This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

PUBLISHED BY THE CLASS JOURNAL COMPANY, 231-241 W. 39TH STREET, NEW YORK CITY

PITTSFIELD

MONUMENTAL IN DURABILITY

Marvelous in the way it will drive your car across Continents. PITTSFIELD Magnetos are the great American Ignition success, for they are of the truly high-tension type, and furnish such an abundance of current that the largest motors start with the first turn of the crank. They give constant, accurate and persistent service for one hundred thousand miles.

Get away from your battery troubles, and do it in a less expensive way than by buying a foreign-built magneto. Yankee genius is just as good as European skill. And the PITTSFIELD Magneto is only one more evidence that America can make as good and economical an article as the world ever saw.

Let us tell you more about it in our booklet on magnetos.

THE AUTOMOBILE

Cobe Trophy Feature of "Fourth" at Indianapolis

INDIANAPOLIS, July 1—For the second time this summer the Indianapolis Motor Speedway opened its gates this afternoon, and despite the excellent card provided a crowd of 6,000 people was lost in the grandstands. This July meet was of a more attractive nature than its predecessor in May, for the reason that it had a number of the trophies up for competition, including the Cobe Cup, the G & J Trophy, the Remy Brassard, and the Speedway Helmet. Two of these were down for decision this afternoon, one of them being the G & J Trophy, which was won by Bob Burman in a Marquette-Buick. The Speedway Helmet offered in the free-for-all at 10 miles, and which was won in May by Bob Burman, was captured this time by Eddie Hearne of Chicago, driving the 120-Benz.

It was a day of sensational record breaking, new marks being established in nearly every one of the stock car events. In the time trials Bob Burman, driving the Buick Special, set 1-4-mile mark at 08.5, an average of 105.87 miles an hour. In the 160-inch class, Herreshoff in a Herreshoff established a new mark of 5:30.61 for this division; Louis Chevrolet in a Buick reduced the 161-230 class 5-mile figures from 4:41.77 to 4:40.8, his own record; in the 231-300 class Burman in the Marquette-Buick smashed the 10, 20, 30, 40 and 50-mile records in the long-distance race for the G & J Trophy. His times were: 10 miles, 8:14.4, previous 8:16.8; 20, 16:21.5, previous 17:10.70; 30, 24:17.1, previous 26:06.11; 40, 32:06.5, previous 34:25.4; 50, 40:03.1, previous 42:03. In the 301-450 class Burman in the Marquette-Buick also cut the 10-mile record from 7:57.1 to 7:56.45, and established a record for 15 miles at 11:46.4. Another demonstration of pace was made by Hearne in the Benz in the Helmet race, in which his 10 miles in 7:13 average 83.14 miles per hour. The G & J Trophy race attracted a field of eleven cars which included Burman and Louis Chevrolet in Marquette - Buicks, Pearce and Heineman in Falcars, Fox in a Pope-Hartford, Harroun and Dawson in Marmons, Moore and Davis in Great Westerns, Miller in a Warren-Detroit, and Cook in a Black Crow. Chevrolet cut out the pace at the start and held the lead for 10 miles, when Burman, sore at being beaten for the Helmet by Hearne, zipped to the front, and set a merry clip for his team-mate. Chevrolet, however, was not beaten so easily, and at the 25-mile post

4—L. Chevrolet, Last Year's Winner, Stops for Gasoline

his number lead the others on the score board. Shortly after this, however, Burman again gained command, and from that point on held his field in check. All the way, however, he was grimly pursued by Chevrolet. Burman, however, had plenty up his sleeve and nearing the finish he felt so safe that he stopped at the pits to take on a supply of gasoline and oil. Even with this he had enough left to beat out Chevrolet by 4 seconds. Pearce in a Falcar had stuck to his task like a veteran and as a result of his perseverance he brought his car home in third place, just ahead of Fox in a Pope-Hartford. In fifth place was Heineman in the other Falcar, while the other two cars that finished the race were the Great Westerns driven by Moore and Davis. Dawson in a Marmon stopped at 45 miles. Miller in the Warren-Detroit went 25, while Harroun in a Marmon and Cook in a Black Crow stopped in their third lap.

Striving for the Speedway Helmet were Zengel in the Chadwick, Hearne in the Benz, Ireland in a Stoddard, Harroun in a Marmon, Louis Chevrolet in a Buick Special, and Wilcox in the Simplex. Burman and Aitken, although entered, did not answer the call the first time, and got out on the track just as the field was breaking for the flying start. It was called no start, however, so Aitken and Burman lined up with the others on the next trial. The early stages of the battle proved a struggle between the National and the Benz, and these two led past the judges' stand on the second lap. Chevrolet's Buick and the Simplex had dropped while Harroun, Zengel, and Ireland were bringing up in the rear. Hearne after this assumed command, having taken the lead away from Aitken who had turned the 5 miles in 3:40.3. Harroun was runner up, but despite his best efforts he could not catch his fellow Chicagoan, who won the race handily with the Chadwick in third place and the Stoddard fourth.

In the minor events Chevrolet in the Buick was the star, winning twice, while his team-mate Burman, in the Marquette Buick, also captured first place honors. The Alco driven by Grant made its debut as a Speedway candidate and won handily while other firsts went to the Herreshoff in its class, and the Maytag in the handicap.

INDIANAPOLIS, July 2—More records were smashed on the second day of the meet, the feature of which was the 100-mile race for the Remy brassard, which was captured by Burman in the Marquette-Buick, with Dawson in a Marmon second, Harroun in Marmon third, and Arthur Chevrolet in a Marquette-Buick fourth. Burman made a remarkable drive of it, going the century without a stop in 20:35.6, as against the previous record of 1:23.43 made by Kincade in a National in the Prest-O-Lite race last May.

Thirteen cars started in this classic and it proved to be a battle between the Marmon and the Marquette-Buick. If points had been counted the Marmon would have captured the honors, but they weren't so the glory goes to Burman, who, however, had to drive his best in order to beat out the new start, Dawson, by a scant 5 seconds. The field that came to the tape included, besides these four, Kincade in a National, Pearce in a Falcar, Cook in a Black Crow, Moore in the Great Western, Louis Chevrolet in a Buick, Stinson in a Black Crow, Aitken and Wilcox in Nationals and Davis in a Great Western.

Kincade in the National made a bold bid for the race in the early stages, and for 30 miles he showed the speed of the party. Then Burman went to the front and flashed first past the tape at 40 and 50 miles. Sixty miles saw a new leader, when Dawson in the Marmon assumed command, holding the pace until past 70 miles. Then Burman came up again and, although grimly pursued by Dawson, the remainder of the distance he held his own and at the end had enough to gain the decision by only a narrow margin. Dawson made a plucky fight of it, but what hurt his chances was the stop he made at the end of the seventh lap for slight repairs which enabled Burman to go to the front. In the next to the last lap Dawson managed to pick up 8 seconds

(*Continued on Page* 30)

Glorious Fourth at Wildwood

WILDWOOD-BY-THE-SEA, July 2—Car No. 13, a large Franklin, driven by Miss Gallagher, belied its number to-day by winning the first sociability run of the North Wildwood Automobile Association from Camden to North Wildwood, N. J., about 121 1-2 miles, with a penalization of only 5 3-4 points.

The allotted time for the run was six hours twenty-three minutes, which included a stop at Alloway of fifteen minutes for luncheon.

In addition to Miss Gallagher, the only other winners of prizes announced this evening were the Chadwick, No. 26, driven by F. B. Wildman, of Norristown, Pa., which won second prize, with a penalization of six points, and third prize, won by Mrs. D. Walter Harper, in a Stanley Steamer, penalty 8 1-2 points.

The official cars of the run were the Franklin, pathfinder; Peerless, which carried the referees; Matheson, patrol No. 1; Peerless, patrol No. 2; Mitchell, press car. The officials were Clyde A. Woolson, referee; Clarence Cranmer, starter; H. N. Sharp, scorer; P. D. Folwell, A. A. A. representative, and J. L. Keir, contest chairman.

WILDWOOD-BY-THE-SEA, July 4—No records were broken at the meet here to-day, the mile track record of 41 2-5 seconds remaining unchanged. The honors of the day very easily belong to J. Fred Betz, 3rd, in his 90-horsepower Simplex, who, in the time trials, negotiated the mile in 45 seconds flat.

The main event of the day, the free-for-all, was captured by the Simplex in 51 1-5 seconds, the Houpt-Rockwell being a good second in 53 1-5. The Knox Giantess was third, Chalmers fourth.

Those who conducted the races were: P. D. Folwell, Representative Contest Board A. A. A.; C. A. Woolson, referee; W. G. Rhodes, assistant referee; C. W. Cranmer, starter; G. Proud and J. Ackley, announcers; A. C. Maucher, chief timer; H. B. Lasher, clerk of course; judges, W. R. Walton, W. Lyman and H. L. Hornberger; umpires, D. W. Boyer, W. Middleton and J. H. Beck; marshals, H. H. Hoffman, L. Smith, A. S. Murphy, L. G. Spingler, Charles Kraus, C. V. Stahl, A. Klein, H. H. Carver and D. C. Bayless. The summaries:

Premier and Moline the

CHICAGO, July 2—By decision of the referee given here to-day No. 1 Premier, driven bŷ Ray MacNamara, was declared winner of the Glidden Trophy, with a total penalty of 93 points. Second honors went to the Chalmers 30, No. 5, with 116 points marked against it. Third place was captured by the Maxwell entry, No. 7, driven by H. E. Walls, with a final score of 208 points. No. 2 Premier was fourth, with 806 points; No. 10 Glide fifth, with 2,247 points, and No. 15 Cino sixth, with 2,414 points.

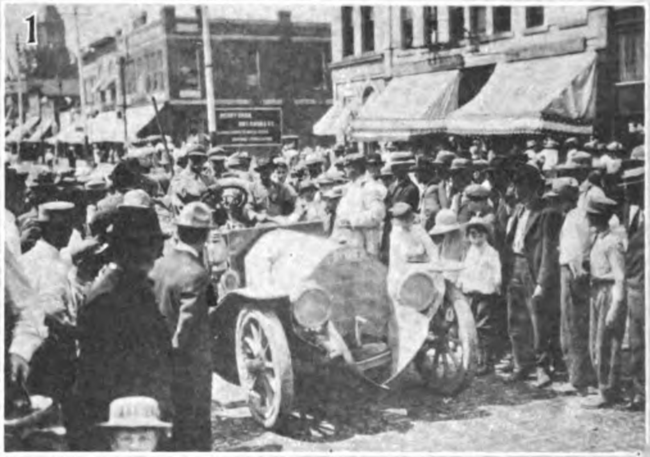
The winning honors in the Chicago Trophy event, which was under the same rules and over the same course as the Glidden, went to No. 100 Moline, driven by C. H. VanderVoort with the lowest score in the field—19 points—the performance of this car being one of the features of the contest, in that it made every checking station on time, took a perfect brake test and lost but 12 points for work on the road and only 7 points in the gruelling final examination at the end of the run in Chicago. This car, according to the rules, had to carry but two passengers, but made the entire 2,850 miles with four passengers, so that in this respect it competed under conditions identical with the Glidden cars. It performed under an 18-mile-an-hour schedule as compared with the 20-mile schedule of the Premier, which was due to its price classification. Second honors in the Chicago Trophy class went to Jesse Illingworth, in No. 107 Maxwell runabout, with 51 points against it. Another Moline, No. 102, driven by F. E. Salisbury, was third with 64 points, and the third Moline No. 101, was fourth, with 481 points. Fifth in this classification went to entry No. 103 Lexington, which it will be remembered broke a side member of its frame running into a sink hole in Arkansas and lost nearly 2,000 points thereby, its final score being 2,042.

Of the twenty-six cars which left Cincinnati three weeks ago on this long test only eleven came into Chicago contesting for either the Chicago or Glidden trophies. There were, however, five of the original entries which entered the city, either as non-contestants or otherwise. Of these five No. 3 Chalmers was disqualified at Oklahoma City for doing work on the car in the garage, but completed the run as a non-contestant, covering every foot of the course. No. 4 Chalmers withdrew at Lawton, Okla., in order to do confetti work, made imperative because of one of the confetti cars breaking down. This car covered the entire distance of the circuit. No. 12 Ohio also completed the entire circuit as a non-contestant, as did No. 106 Falcar, driven by Van Sicklen in the Chicago Trophy division. To this list must be added two four-cylinder Cartercars, that, owing to rear axle trouble, had to lose a day's time and cut the course 100 miles or so in order to catch up with the procession. One of these cars it is asserted actually traveled further than the route called for because of getting lost.

There were several cars which accompanied the tour from the start in a non-contesting capacity, and which covered every mile of the route, these being a Chalmers confetti car, a Columbia car carrying the referee and acting as pacemaker, two Cadillac gun cars carrying four people each, as well as a quick-firing gun, the Halladay press car and the Great Western press car.

As the complete tabulation shows there were but five cars in the whole tour that made perfect control performances—that is, were not late at one checking station on the entire tour—these five cars being: No. 1 Premier, No. 5 Chalmers, No. 7 Maxwell, No. 100 Moline and No. 107 Maxwell. In this respect the Maxwell entry made the best showing, in that it entered but two cars in the two contests and both of these made all controls on time from start to finish. There were two Premiers entered, but one lost out on controls, and of the three Molines, only one was clean on all the checking stations. Only one of the three Chalmers made all checking stations on time.

The final examination at the completion of the tour was a strenuous one in every sense of the term. The first phase of this contest was a brake test in which the cars crossed the braking line at their competing speed of 18 or 20 miles per hour, and their distance was taken for stopping with hand brake, and then with foot brake. Only three of the eleven cars made perfect brake performances—that is, stopped the car under 50 feet with each set of brakes, these three cars being No. 100 Moline, No. 101 Moline and No. 107 Maxwell. There were four other cars that stopped within the 50 feet with the foot brake, but failed with the hand or emergency, these being No. 5 Chalmers, No. 7 Maxwell, No. 102 Moline and No. 103 Lexington. The winning Premier No. 1 was assessed 16 points on its foot brakes, and 48 points on its hand brakes. No. 5 Chalmers, which finished second in the Glidden, was assessed 36 points on the hand brake. No. 7 Maxwell, which lost 33 points on the hand brake, lost these due to a wood shoe forming a part of the braking surface of one brake having been lost.



1—Premier at Marengo, Iowa, Noon Control

2—Chalmers "30" Checking in at Davenport, Iowa

The second phase of the final test was for clutches, the cars having to bring the front wheels to an 8-inch curb and either climb the curb, spin the rear wheels or stall the motor. Only one car was penalized on this score, that being the Lexington No. 103, which was penalized 5 points. After the clutch test the cars were garaged and completely washed so that the technical committee had an opportunity to look over every detail of them for bent, impaired or lost parts. In order to do this the spring wrappings were taken off and no precaution neglected to make the test as thorough as possible. This test revealed several broken fender irons, loose spring clips, and in four or five cases

Glidden Tour Winners

the front springs had slipped back or forward on the axle. Two or three cars showed loose spokes in the wheels and there were two cases of hub-flange bolts being loose. Because of having carried too much weight on the running boards there were two cases of fender and running board brackets having been broken. It was remarkable that after so long and gruelling a test there should have been little trouble as the examination revealed. The complete penalties assessed against each car appear in the tabulation herewith, as well as the points levied in each case.

In summing up the performance of the eleven cars it is most interesting to note that the three Moline entries and No. 107 Maxwell passed the cleanest examinations at the finish. No. 100 Moline had but 7 points, No. 101 had only 3 points and No. 102 set the record of the trip with only 2 points against it, one being for a muffler rod nut lost and the other for the brass sleeve outside of the steering column being loose. The No. 107 Maxwell received but 8 points.

3—Molines, 100 and 101, and Parry No. 105 at Guthrie Center, Ia.
4—Maxwell Checking In at Wichita, Kansas

In the Glidden end of the contest the No. 1 Premier passed the best examination with 15 points assessed against it; then came No. 2 Premier with 20 points and No. 5 Chalmers with 41.

There was not a solitary car that did not receive technical penalties for work done on the road. The car with the cleanest record in this respect was No. 1 Premier with 9 points for taking on water and repairing and replacing fan belts. No. 100 Moline was a close second with but 12 points. The No. 5 Chalmers made the most remarkable road record, in that it went for five days longer than any of the other contestants with its clean road score, and finally lost it on the run into Wichita, Kan., when a fender iron crystallized.

The announcement of the Glidden award was delayed until to-day because of a protest entered by the Chalmers Company against the Premier entry, this protest having been handed to the referee in Kansas City. The protest was on the grounds that the Premiers were not stock in that they carried 1 1-2 gallon oil tanks on the right side under the tonneau floor, and had a hand pump fitted for pumping the oil from these tanks to the crankcase of the motor. An investigation was made and the Premier company claimed to have 74 cars fitted with this form of oiler. The referee would not allow the protest on the ground that the protest, which took into consideration the validity of entry, should have been made before the start of the tour. It is understood that the Chalmers Company is discussing the question of appealing the matter to the Contest Board, which it has the privilege of doing.

The Chicago Motor Club arranged for a checking station in Garfield Park, on the outskirts of the city. At this point a procession was formed of all the contesting and non-contesting cars in the Chicago and Glidden trophies, led by a band.

In the final technical examination detailed penalties were inflicted as follows:

Glidden Trophy

Premier Car No. 1—10, front wheels, spindles, loose; 1, water connection, leaking; 2, engine hanger belt broken; 2, spring clips loose—total 15.

Premier No. 2—2, cylinder head plate, leaking; 5, spring leaf broken, right rear; 5, spring leaf broken, left rear; 1, ignition shaft jaw coupling, loose; 1, hub flange bolt, broken; 4, rear reach rods on foot brakes, bent; 2, rear reach rod lever on foot brakes, bent—total 20.

Chalmers, No. 5—6, fender iron broken; 2, steering gear loose on frame; 1, muffler cutout wire broken; 2, body bolt lost; 1, body bolt loose; 2, shackle bracket loose; 2, ignition terminal broken; 25, tie rod bent—total 41.

Maxwell, No. 7—2, bumper plate lost; 4, four spring clips loose; 5, spring leaf broken, right front; 2, grease cup lost; 5, front wheel loose; 5, steering yoke pin loose; 50, defective brake; 1, body bolt loose; 2, fender bracket loose; 5, front wheel bearing loose—total 81.

Glide, No. 10—5, spring leaf broken, right rear; 2, muffler loose; 150, rear axle housing parted; 2, fan belt lost; 25, fan pulley, broken flange; 1, radiator, leaky connection; 5, spring leaf broken, left front; 6, three spring straps lost; 5, front wheel, loose, left; 5, front wheel, spokes loose, left; 5, front wheel, loose, right; 5 front wheel, spokes loose, right; 5, fender broken; 6, step bracket, broken; 15, steering column crank loose—total 242.

Cino, No. 15—6, three grease cups lost; 15, rear spring bracket, bent; 1, pressure pipe on gasoline feed line, loose; 20, radiator leaky; 2, engine bolts, loose; 10, front wheels, both loose; 2, fender loose; 1, muffler, final exhaust pipe loose; 12, two fender irons broken; 5, spring leaf broken, right front; 5, spring leaf broken, right rear; 5, spring leaf broken, left rear—total 84.

Chicago Trophy

Moline, No. 100—5, front wheel bearing, loose; 2, fan blades, impaired—total 7.

Moline, No. 101—1, gasoline leak; 2, steering column, finishing plate on dash, lost—total 3.

Moline, No. 102—1, muffler nut, lost; 1. steering column sleeve loose—total 2.

Lexington, No. 103—5, ball and socket timer connection broken; 10, both steering yoke bearings loose; 5, wheel bearing loose; 2, grease cup lost; 500, frame side member broken—total 522.

Maxwell, No. 107—1,spring clip loose; 2, nut on step bracket bolt lost; 1, front union on muffler loose; 2, rear fender screw lost; 2, fan bolt lost—total 8.

Owen Cars with Big Wheels and Left-Hand Drive

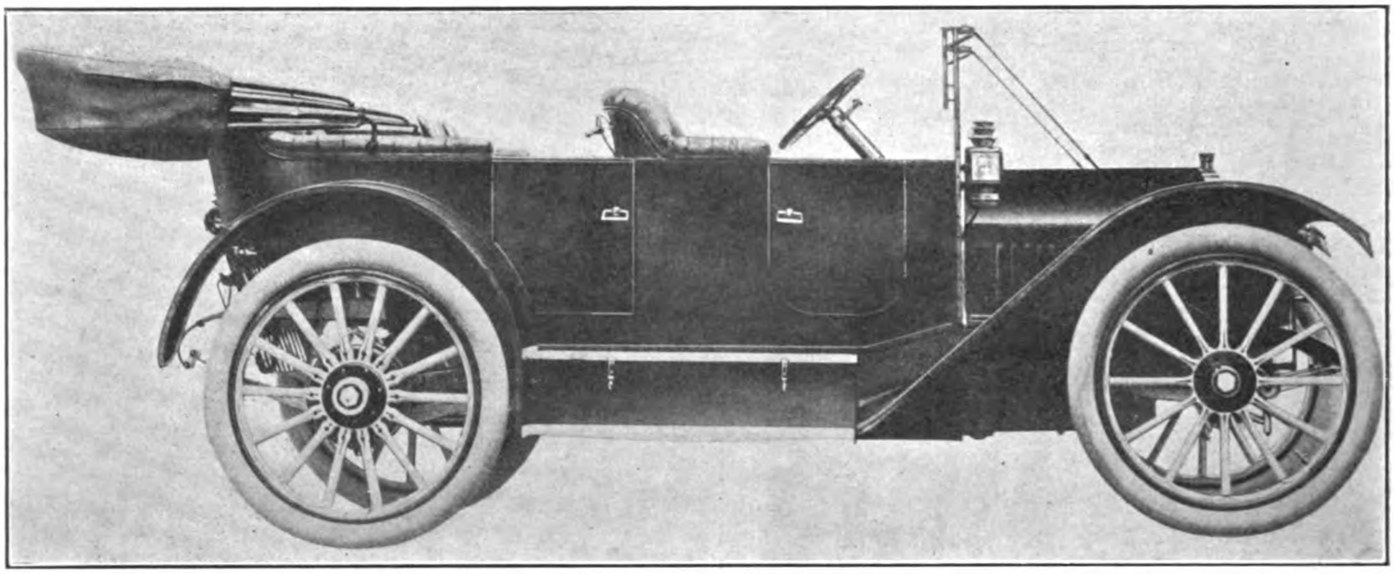

Fig. 1—The car complete with a gunboat type of body, left-hand steer, control amidships and large diameter wheels

COMBINING, as it does, the results of past years of experience as mechanics, designers and producers, unhampered by any questions of factory equipment, firm policy or executive prejudice, it follows that the 1911 product of the Owen Motor Car Company, of Indianapolis, Ind., should represent the last word in latter-day motor car construction.

The fundamental points upon which the Owen product has been built include, among others, these primary essentials: long-stroke engine, left-hand steer, right-hand control, low gravity, closed-front, straight-line body and high wheels.

While much has been said and written as to the relative merits of right and left-hand steer, it is the experience of many qualified drivers that a car can be handled much better from the left than from the right. With the traffic rules in force in this country it is more essential that a clear view of the road to the left be had than to the right; a left turn is fraught with more danger than one to the right; besides, it permits the occupant of the guest seat to alight directly on the curb and not in the mud of the street, at the imminent risk of being run down from the rear by an automobile traveling in the same direction.

Forty-two-inch wheels, the standard equipment of the Owen, make for ease in heavy going, increased traction area, comparative freedom from side-slips and high mileage—in the latter respect the builders claim an increase of from 200 to 300 per cent.

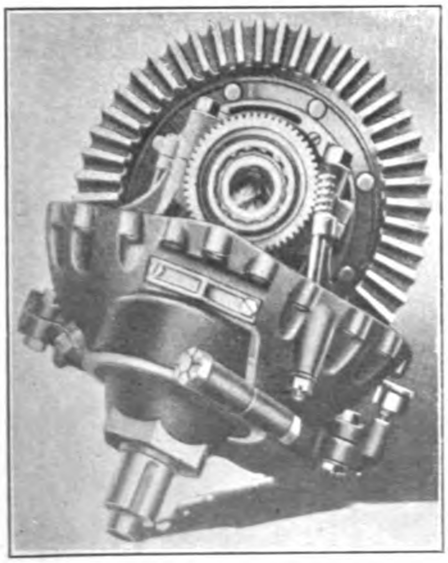

Fig. 2—Differential and bevel drive unit which are separately assembled

The double-dropped and offset frame members facilitate a greater turning angle and enable the production of a high-wheeled car with a lower gravity with respect to spring suspension than is possible by ordinary construction.

The closed-front, straight-line body, the standard Owen equipment, is a much-appreciated guard against wind and weather, and a preventive of trailing robes or garments. Besides, the straight lines set off the finish, all the mouldings being worked out of the solid wall of the sides. The absence of double mouldings and other embellishments conveys an idea of unadorned simplicity.

Notable Mechanical Refinements in the 1911 Car

Passing from the general appearance of the car as it is shown in Fig. 1 to the motor, the left side of which is presented in Fig. 5, opportunity will be taken to comment upon the excellence of the magneto installation. It rests upon a pedestal which blocks it up to the exact right height, so that the armature spindle is in correct alignment with the extension of the driving shaft, and a universal joint intervenes, the function of which is to compensate for such minute differences as may be inadvertently interposed. The magneto is so placed that the wiring of the high-tension system passes up through a conduit to the distributing box, which is parallel to the line of spark plugs, and by a special system of terminals the spark plugs are so joined that each of them may be disconnected with a minimum of effort for purposes of testing.

The upper half of the motor case carries a pair of arms which extend out to the chassis frame, but instead of a sod-pan the aluminum case is flanged out between the arms, serving as a perfect substitute for the sod-pan, and affording a platform on which to rest the auxiliaries, and to place tools which may be used in making ad-

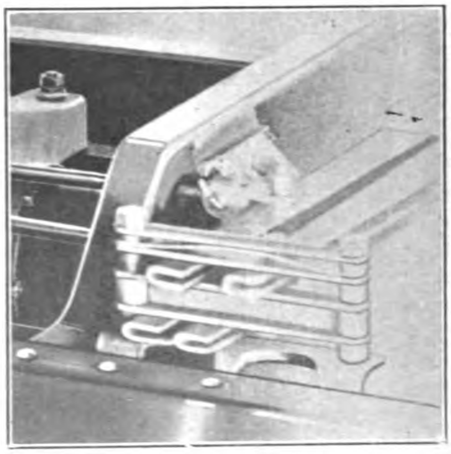

Fig. 3—Details of the equalizing bars for the brakes

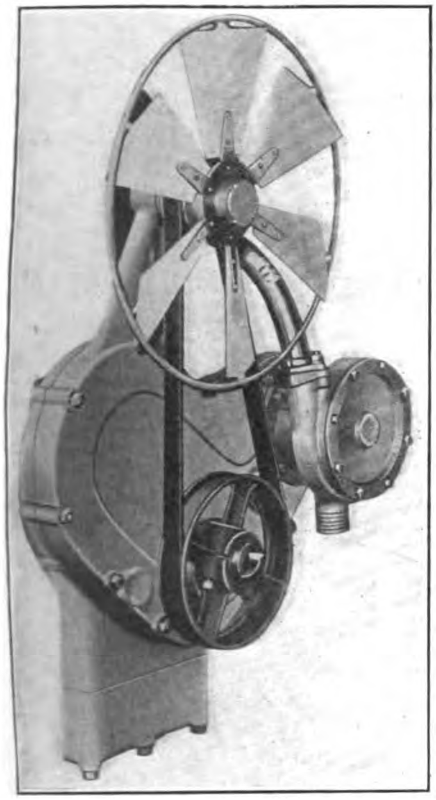

Fig. 4—Front end of the motor showing the fan, method of driving, and water pump

justments on the road. As a further incident of this construction, this integral flanging acts as a stiffener between the arms. The cylinders are cast in pairs, and are of the T-head type, there being two pairs for the 4-cylinder motor. Glancing at the illustration again, it will be observed that one of the tappet housings shows at the rear above the flywheel. The row of valve mechanisms comes on the right side of the motor, and the lifts are enclosed by a telescoping sleeve system, so that they are protected from the dust accumulations, are muffled, and may be gotten at readily. The many other nice mechanical refinements are so clearly shown in the illustration as not to demand further favorable comment.

In the cooling system, beyond stating that the radiator is of well-chosen capacity, additional refinement will be the better understood by referring to Fig. 4, which shows the front end of the motor, the fan bracket and fan, also the belt, and the driving pulley which is double-shrouded and extends out from the halftime gearcase, being pressed on the stub end of the crankshaft. The centrifugal pump is also shown at the right of the fan belt; it is of unusually large capacity and is driven by a pinion which meshes with the halftime gear system. Lubricating oil is carried in a commodious well in the bottom half of the crankcase, and the gear pump which circulates the oil is inserted in the case, and readily detached for purposes of cleaning or inspection. Fig. 7 shows the filler for the lubricating oil and offers an excellent idea of the nice eye to detail which the designer expended upon this car.

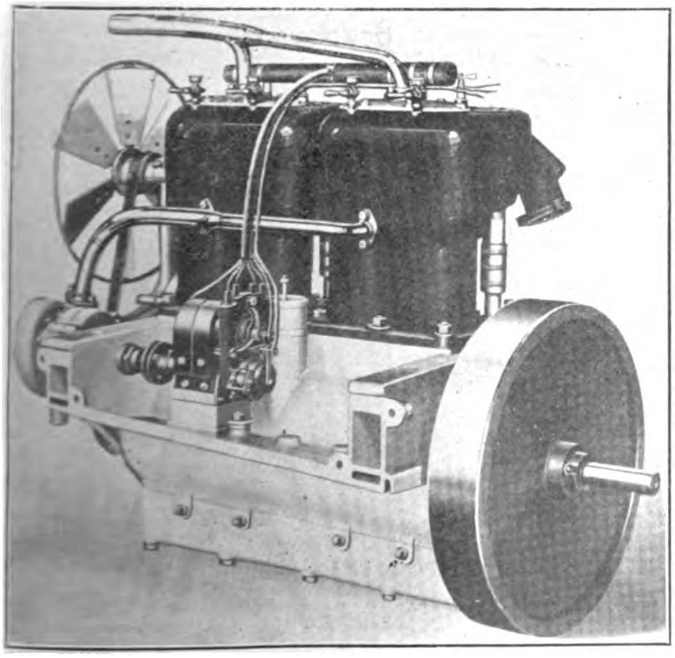

Fig. 5—Left side of the motor presenting details of the magneto mounting, method of wiring, and shape of the motor case

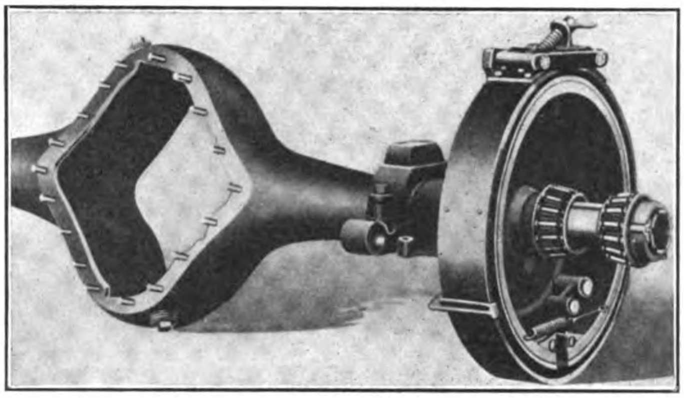

Fig. 6—Live rear axle housing presenting Timken roller bearing mounting, brakedrum, and two sets of brakes

A part of the rear axle is given in Fig. 6, and shows the Timken roller bearings, large diameter brakedrum, external constricting band and internal expanding band, also the spring perch, and the enlargement in the mid-position of the axle which takes the bevel-and-differential unit which is shown in detail in Fig. 2. The strength of the rear axle is adequately depicted in Fig. 6, but to do the subject justice it will be necessary to enlarge somewhat upon the advantages which are present in the unit method of assembling the bevel drive and differential gear sets. This set is mounted on annular-type ball bearings; the bevel pinion and its meshing gear are fixed in their relation by a definite machine method which offers no opportunity for a curious autoist to throw the pinion and gear out of their true relation, but this point ranks low in the series of advantages as compared with the opportunity which is afforded the men who work on the system; they are enabled to do a definite and accurate machine job, using suitable templets and gauges on a jigging basis. Noiseless performance, coupled with high efficiency and long life, are therefore normal expectations. Fig. 3 is just a detail in the chassis work. It shows the equalizer bars for the brakes, and their guides above the level of the chassis frame.

Goodrich, Diamond, Fisk or Firestone are tire options.

The Owen price propositions include: Six-passenger touring car, fully equipped, $4,000; two-passenger runabout, fully equipped, $4,000; Berlin (fore-door) limousine, $5,400; Berlin (fore-door) limousine, body, $1,800; chassis, $3,600.

Palmer & Singer Offer Four Models for 1911

ADHERING to their 1910 policy, Palmer & Singer announce four models for 1911—two six-cylinder and two four-cylinder cars. The sixes will be the Six-Sixty and the Six-Forty; the fours, the Four-Fifty and the Four-Thirty. The demand for more power by the four-cylinder clientèle of the company has been met by the introduction of the Four-Fifty, while the new Six-Forty has been introduced for those of the Palmer & Singer six-cylinder devotees who desire a lower-powered, smaller car. The Six-Forty is equipped with either five-passenger touring or closed body, as is the Four-Fifty. The other models are offered in the same wide range of body equipment which characterized the 1910 cars. Uniformity characterizes the principles of construction underlying all four models; the engineering motif being the same for all the cars made.

The reliability and smooth-running qualities of the Palmer & Singer are to be attributed in large measure to the special triple jet carbureter used on them. By its use the mixture of gasoline and air is automatically controlled so that it always suits the motor speed and the climatic condition, giving uniformity and economy of fuel.

While the pressure feed system is normally used, gravity feed will be provided on small runabouts, if desired. Pressure is supplied by a pressure regulating valve on the exhaust side of the motor, having a special safety adjustment. A gauge and hand air pump on the dash are provided.

All Palmer & Singer motors have been designed for the high-tension dual ignition system with separate spark plugs, both being located on the inlet side of the motor. A battery high-tension distributor and single vibrating coil on the dash and a Bosch magneto are provided, a switch permitting either, or both, to be employed.

Barring the difference in sizes, the models are identical in design and workmanship with the Six-Sixty, except that an annular ball bearing is used for the front crank-shaft bearing of the Six-Forty, the cylinders of the little six are cast en bloc, three together, and the valves on the smaller four are both on the same side.

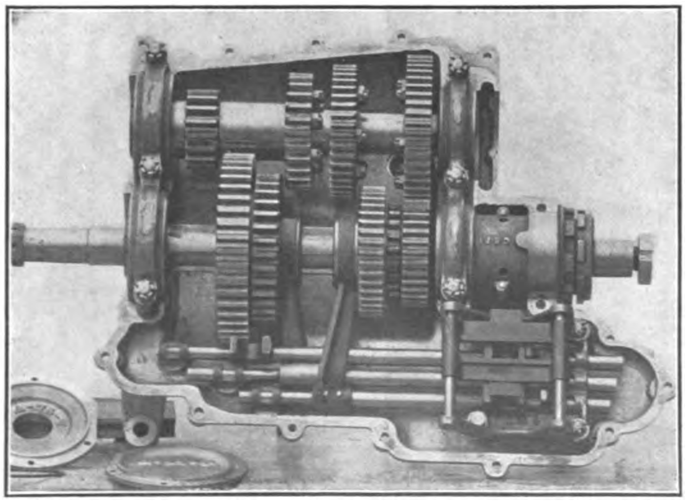

Fig. 2—Four-speed selective sliding gear transmission, with annular type ball bearings, and selectors within same housing

The clutch is housed in the flywheel in the two larger models, while in the smaller pair it is in a separate oil-tight compartment of the transmission case to economize space and permit the use of a longer propeller shaft.

The drive is direct through integral gear on the fourth speed on the Six-Sixty and Four-Fifty models, and direct on the third on the lower-powered cars.

Thirty-six-inch wheels, front and rear, are the standard equipment on all except the Town Car, with conical roller bearings on the larger models and imported annular ball bearings on the smaller. Diamond tires, of a size suitable to the weight of the different models, and amply large in all cases, are Palmer & Singer standard equipment.

Mechanical Refinements on a Six-Cylinder Basis

The general appearance of the car is shown in Fig. 1, referring to the 40-horsepower, 6-cylinder power plant, and among the prominent points is the fact that the length of the bonnet is not marked, which is an indication that the 6-cylinder power plant is compactly designed.

The new "Little Six" motor is shown in elevation in Fig. 4, looking at the right side with magneto in front, driven from a shaft which extends out of the halftime case, the other end of the shaft having a pinion which meshes with the halftime gear system. The carbureter is located in a mid-position, high enough up to be accessible, and is connected by a straight away

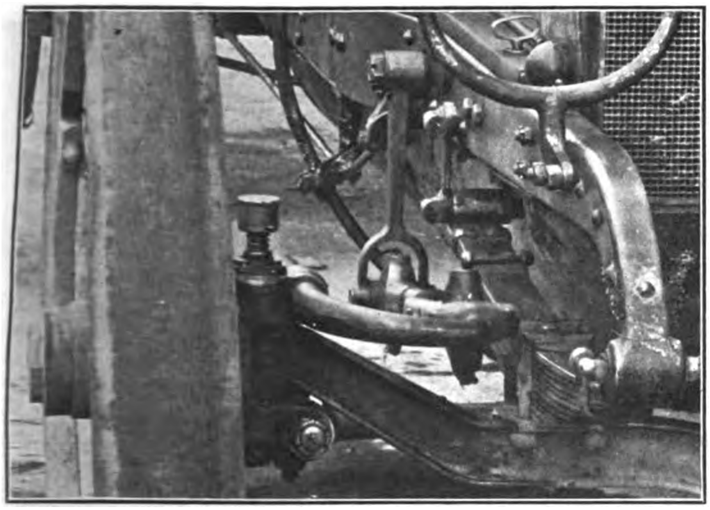

Fig. 3—Detail of front axle presenting an I-section with flat perches for semi-elliptic springs, substantial knuckle with a through pin and means for lubrication

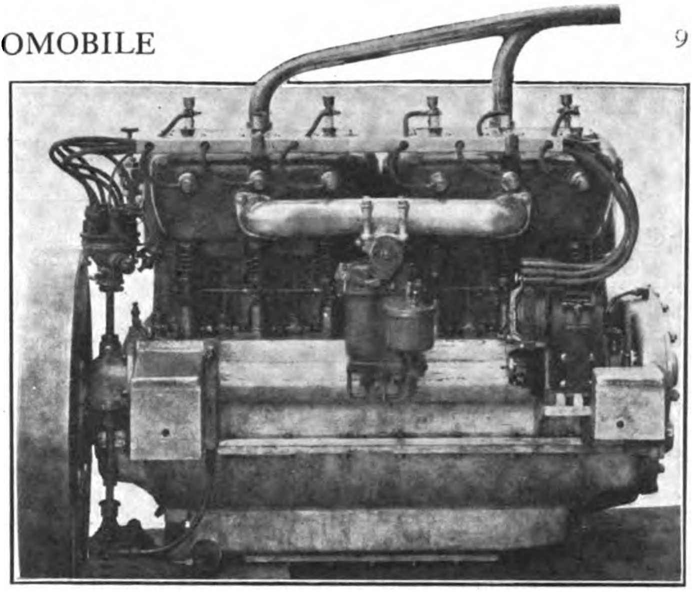

Fig. 4—Right side of "Little Six" motor, showing magneto in front, connections to spark plugs and timer at back, also the carbureter and its manifold connections

manifold to the two pair of cylinder castings, there being three cylinders in each casting. The wiring from the magneto extends in a loop up to a box, and a lead is distributed out of the box to each of the spark plugs in turn; some of the leads pass beyond, back to the timer, which is located at the rear of the last cylinder above the line of the diameter of the flywheel; rotation is given to the timer by a vertical shaft through a gear set on the end of the camshaft. The crankcase is in two halves flanged on the horizontal center and below the dip of the connecting rods, a long oil well is provided, and oil circulation is maintained by means of a gear pump which is driven by a vertical shaft in line with the vertical shaft which gives rotation to the timer. There is a cover on the underside of the lower half of the crankcase which may be removed at will and sediment as it collects in the bottom of the oil well may be scraped out through this accommodation. The flywheel is of large diameter and relatively light, considering the flywheel effect afforded; the spokes are fan fashion, and serve for pulling air through the radiator in the cooling process.

In order not to confuse the situation, the illustrations and discussion here will be confined to the simple process of indicating the character of the work done, and the methods of design, it being the case that Palmer-Singer engineering is common throughout the four different models which are offered to 1911 patrons. As an illustration of transmission gear work, Fig. 2 is presented. It shows a four-speed and reverse sliding gear system of the selective type with the selective mechanism enclosed within the same case. The lay shaft is short and relatively thick, with all of the gears flanged on, excepting low, which is formed integral. The sliding members are of substantial construction, slip over splines cut integral, and direct on "high" is obtained by the meshing of an external with an internal involute type of gears. The shafts throughout are centered on annular type ball bearings of large sizes, and they are accurately fitted into their housings in the lower half and maintained in position independently of the upper half, bolting yokes being used for the purpose. The upper half of the case serves merely as a protection, and handhole covers are provided therein for the purpose of inspection. The detail of the reverse gear is shown in Fig. 5; it runs on a spindle in a yoke of a bell crank member which oscillates on a pinned fulcrum under the direction of a cam, which engages a roller attached to the free end of the bell crank member. Instead of sliding into reverse, this pinion is swung into mesh, describing an arc equal to the radius from the center of the fulcrum pin to the center of the pinion pin, so that engagement of the reverse pinion is in the radial relation with its mate.

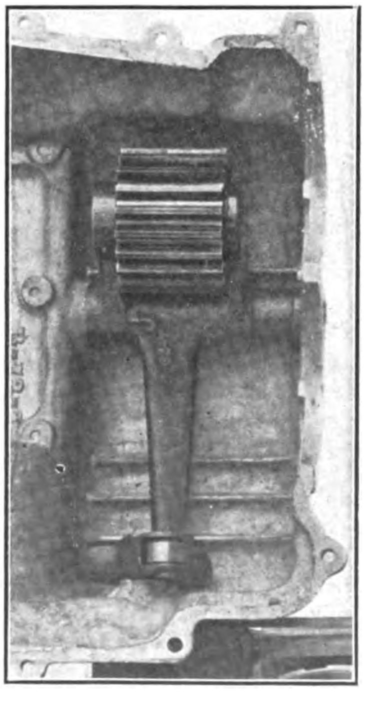

Fig. 5—Detail of reverse mechanism which lays in lower half of gear-case and is operated by a sliding cam engaging a roller on end of lever

As a further indication of the methods of design utilized in these products Fig. 3 is offered. It shows the I-section front axle, method of supporting the half-elliptic front springs, shape of the chassis frame at the point of fastening, how the lamp brackets are bolted on, and the steering knuckle with its large pin, and a substantial grease cup to provide lubrication, also the steering arm and a perspective of the connecting link between it and the steering lever which extends out to the chassis frame from the steering gear. Substantial universal joints are used in the steering system, and locking nuts obtain at every point so that when the parts are assembled in their tight relation they are so maintained, but disassembling is relatively simple, due to the definite means employed, and the locking nuts which may be undone as an initial effort.

Worthy Points for Special Mention

In the two larger models the clutch is housed in the flywheel, whereas in the remaining models it is in a separate oil-tight compartment of the transmission case. In all models the multiple disc type of clutch is used; it is composed of 47 discs of saw-blade steel, operating in an oil bath. The clutch spring is adjustable, and the clutch trunnion is lubricated by two grease cups. Transmission is by propeller shaft to the live rear axle, and the bevel gear set is of nickel steel. The rear axle is of the full floating type, and hardened square ends engage with the differential pinion. Steel dogs transmit the power from shafts to road wheels. The rear axle housing is trussed, and a large removable cover gives access to the differential set for purposes of inspection and lubrication. Imported annular ball bearings are used throughout. The details of the brakes are worked out to a fitting end. The service brake operates by a foot pedal, is of the internal expanding type lined with "Raybestos," and the emergency brakes are operated by a side lever, they being of the external constricting type. The channel section frames have four cross members.

Empire "Twenty"—Hails from Indianapolis

PROCEEDING on the theory that a plethora of models means increased cost of production and a corresponding increase in selling price, the Empire Motor Car Company, of Indianapolis, is devoting the best energies of its entire plant to the production of the Empire "20" Model C—a two-passenger roadster, swung low and presenting a stylish, racy appearance. Every detail throughout the distinctive and exclusive design is executed with the two-passenger idea in mind. Rumble seats, surrey seats and other combinations are not offered, and it is evident at a glance that the car is not in the convertible class.

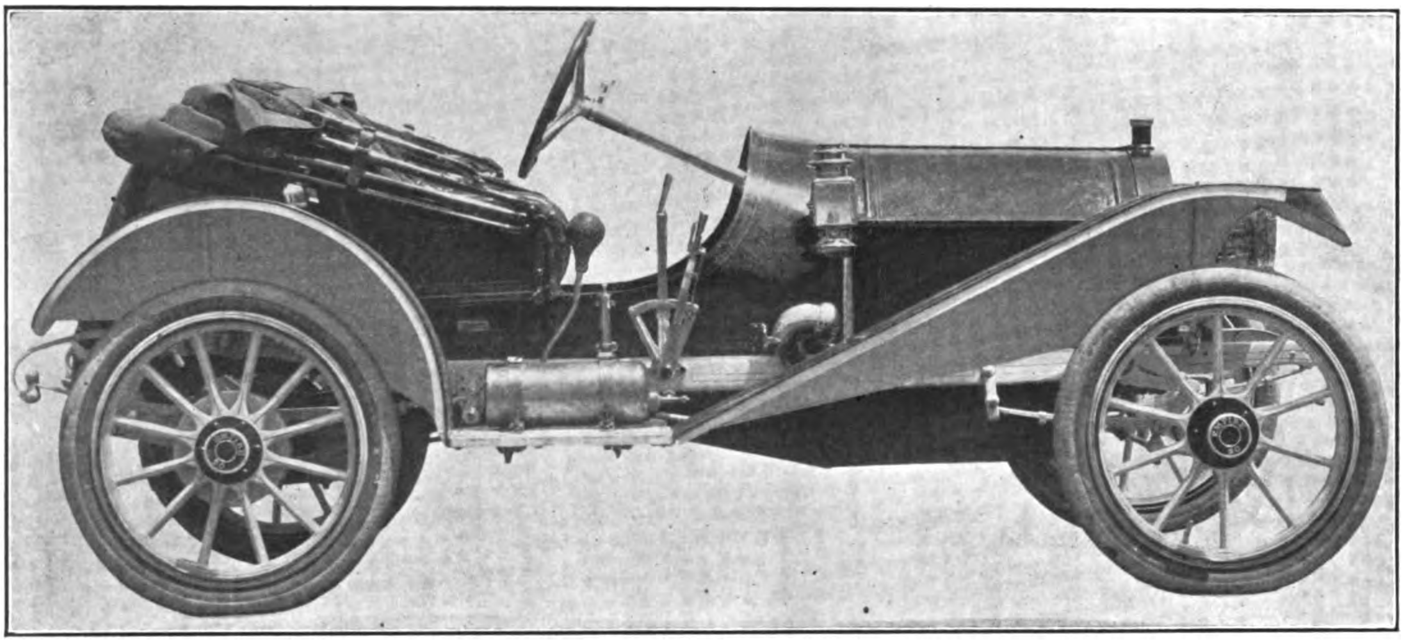

Fig. 1—Side View of Model C Empire "Twenty" Automobile, showing flaring mud guards, low seat, convenience of side levers, etc.

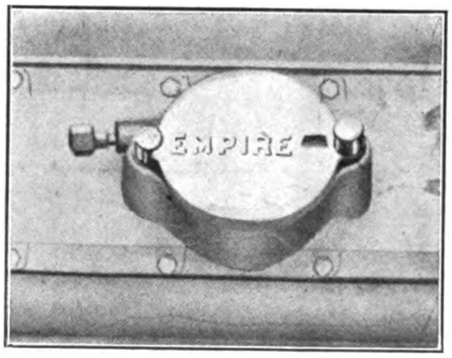

Fig. 2—Removable handhole cover on detachable plate of upper half of crankcase

The Empire "20" is not an assembled car, being made entirely within the company's plant. The spring suspension, the design of the seats and their location with reference to the axle, the drop frame, the large wheels and the enclosed dash are points of refinement that give the car exceptionally easy riding qualities and make it a roadster of the most comfortable type.

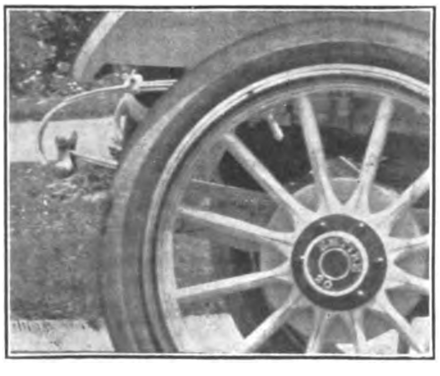

Fig. 3—View of rear suspension, showing three-quarter elliptic springs

Unit Power Plant

The motor is of the 4-cycle, water-cooled type, rated at 20 horsepower, with T-head cylinders having valves on opposite sides as shown in Fig. 5. In this view, the magneto is indicated on the left side of the motor toward the front, and a Wheeler & Schebler carbureter is located back of the magneto, but high enough up to be in a perfectly accessible position. The halftime gears are enclosed in an oil-tight case, and the magneto is driven by a stub end shaft which projects back from an extension of this case, the other end of the shaft having a pinion which meshes with one of the halftime gears. The cylinders are of the barrel type, cylinder head, intake and exhaust manifolds, also the water jacket, being cast integral. This type of cylinders presents a neat and symmetrical exterior, and from a thermodynamic standpoint offers advantages which result in economy of performance.

The magneto is supported by an auxiliary, utilizing the dual system of ignition. Lubrication is by means of four deep compartments formed in the crankcase into which the connecting rods dip, and provision is made on the caps for the picking up of sufficient oil to produce copious lubrication. The capacity of the lubricating system is three quarts of oil, and a hand pump is provided for replenishing purposes. In the cooling system a vertical tube radiator is employed, and circulation is on the thermo-syphon principle. The clutch is of the cone type, leather-faced, and the leather is held into intimate engagement by means of six plungers actuated by springs. The general appearance of the car is shown in Fig. 1; it is designated as

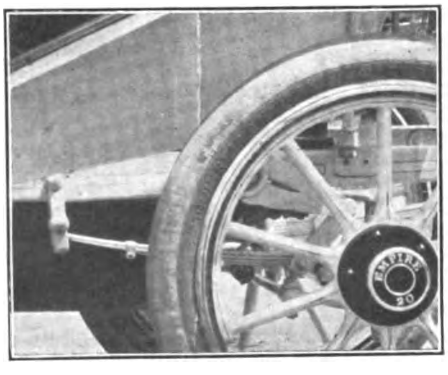

Fig. 4—Part of front suspension, showing details of half-elliptic spring shackle.

Model C Empire; presents a racy appearance, and affords protection to the occupants of the seat due to the considerable overhang of the dash. In this view the cape top is folded back.

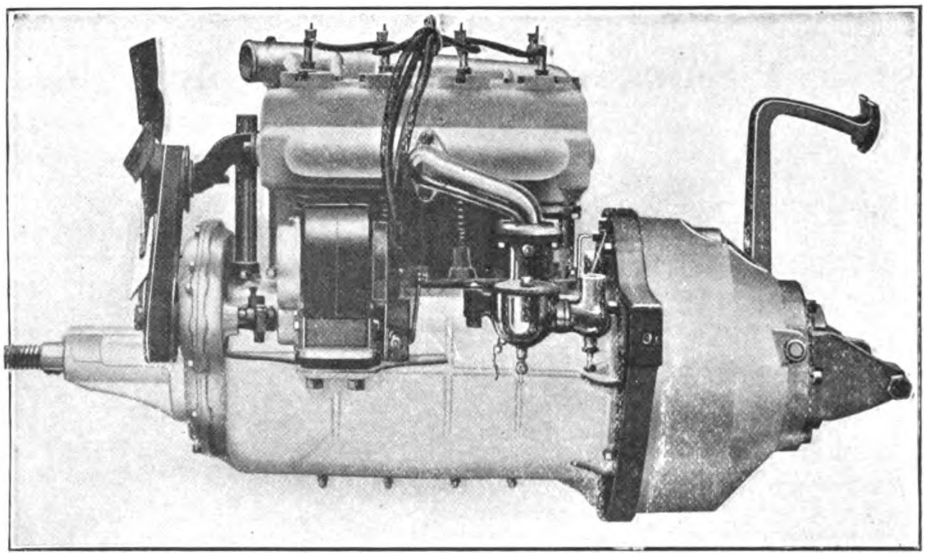

Fig. 5—Side view of self-contained power plant showing magneto and carbureter on left side of the motor

Carefully Thought-Out Details

Fig. 2 shows a quick detachable handhole cover on the crankcase, which is fitted to the crankcase plate; the latter is bolted on and may be readily removed if, for any reason, it is desired to have access to the bearings. Fig. 3 shows the three-quarter elliptic springs, and the method of shackling, also the wheel hub, wood work, and large diameter brakedrum. Fig. 4 presents the shackling of the half-elliptic front springs, also shows the front-wheel construction and the shock absorber, together with the method of attaching same. Fig. 6 is a view of the rear axle showing the three-quarter elliptic spring, its mounting on the perch, the fastening of the shock absorber, also the brakedrum, how it is protected from mud accumulations, and other details along engineering lines. Fig. 7 is a view of the driver's side, showing the relation of the seat to the dash, side levers, oil pump, rake of the steering post, and the Prest-O-Lite tank on the running board.

General Characteristics of the Model C Car

The 20-horsepower motor has cylinders 3½ x 4-inch bore and stroke respectively, and in the construction of the car it was the idea to maintain a certain harmony of the relation of the parts to each other, taking into account the maximum possible torque of the motor and the greatest strain which could be brought to bear in a breaking effort. The side frames are of pressed steel, open-hearth stock, 3½ inches deep, with 1½-inch flanges, with a 3¾-inch drop at the rear.

Among the other advances there are questions of refined material, as the crankshaft, which is drop forged of special alloy steel, and thereafter heat treated to impart rigidity and kinetic qualities. The bearings are of Parsons white bronze, and the fitting is done with precision. The camshafts are drop forged in one piece with integral cams; cementing stock is used, and the cam faces are hardened to a sufficient depth to survive in service. The valve dimensions are large, the head being 1¾ inches in the clear, which is half the diameter of the piston. The compression is regulated with a view to utilizing these large diameter valves to advantage, and the torquing performance of the motor is on a constant basis as the speed increases.

Selected second-growth hickory is used in the wheels, which have 10 spokes in front, 12 in rear, with Q. D. rims. The tires are 32 x 3½ inches both front and rear.

The blue body, of sheet metal, semi-torpedo type, with inclosed dash, and cream running gear, is an especially natty combination.

The equipment of the Empire consists of 6½-inch gas lamps with nine-inch flare, brackets included; oil side lamps, tail lamps, horn, complete kit of tools, tire repair kit and tire pump.

The price is $950, f. o. b. Indianapolis. As regards extra equipment—a Racy type top will be fitted for an additional $50; folding glass front, $25; Prest-O-Lite tank, fitted and gas line installed, $20; 60-inch tread (for Southern travel), $20.

Digest Along Technical Lines for the Engineer

Means for operating a motor at high temperatures and without water or air cooling by separating piston stroke from gas expansion——Spring suspension which reduces up and down motion——Common sense in calculation of valve springs——Paris 'bus run with coal gas.

Radical means for avoiding radical cooling of internal combustion motors are suggested by Martin-Saxton, an engineer. The only reason for intensive cooling is the need of lubrication between piston and cylinder, which requires a temperature of less than 300 degrees for the interior cylinder walls. And, for a little matter of lubrication, one encumbers the motor with elaborate apparatus which is liable to get out of order. Moreover, this cooling absorbs 44 per cent. of the heat, 24 by convection and 20 by radiation. It must be gotten rid of. Impossible! No, simplest thing in the world. All that is necessary is to separate the working chamber of the hot gases from the zone of the necessary sliding joint between piston and cylinder. The cylinder *C*, in which the piston plays, is prolonged upward by means of a closed cylinder of slightly larger interior diameter, which is to be the working chamber for the gases and whose walls may be of any material, provided they will resist the pressures, the temperatures and the vibrations. Then, the piston *D* is surmounted with a plunger *B* of an exterior diameter slightly smaller than that of the stroke-cylinder, and of such length that at the top of the stroke it obstructs the gas chamber almost completely and at the bottom of the stroke it masks the stroke portions *C* against the heat from the gas chamber. By this procedure the sliding joint between piston and cylinder is never reached by more gas than that which penetrates through the slight clearance between the plunger and the cylinder walls and receives only an insignificant quantity of heat. Hence the walls don't get hot and lubrication is accomplished without any difficulty. Cooling is dispensed with. In the industrial motors, fuel economy is paramount; the heat losses should be reduced to a mimimum; the walls should be non-conductors. The gas chamber should be coated interiorly and the plunger exteriorly with refractory material. To avoid premature ignition, the explosion type should be abandoned for the type giving relatively slow combustion and expansion of the gases, as by employing separate pumps for the liquid fuel and for the air. (Some trouble may be apprehended in making the fuel reach the gas chamber without disintegration through highly heated pipes and valves.)

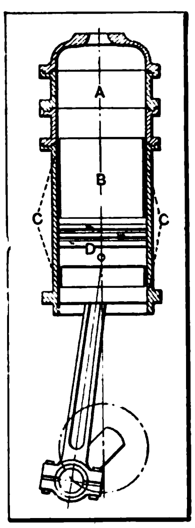

Fig. 1—Martin Saxton Motor

With a light motor, as shown in Fig. 1. fuel economy is secondary, and it should be sufficient to use belts of metallic walls separated by rings of non-conductive material. By having several belts and several rings, the temperature of the ring nearest the stroke portion of the cylinder may theoretically be reduced to less than one-half of the degrees reached in the exhaust gas, even if the insulation rings are supposed to be very thin. To prevent dislocations from expansions and contractions, encasings with limited lateral play are employed.

As in these light motors the walls are metallic, they will radiate exteriorly and will not reach temperatures which will produce premature combustion, hence any type of motor may be used: four-cycle, two-cycle, high or low compression, rapid or slow ignition. To effect a transformation of an ordinary motor, only the combustion chamber need to be changed and a plunger added to the piston. Simple! (The author must have in mind, it seems, the addition to his system of the ordinary air-cooling provisions, if he shall hope to avoid premature ignition.) Valves might get red hot. They, too, should be kept away from contact with the superhot gases. By a special arrangement each valve is masked except at the moment when it functions. This arrangement consists, as shown in the illustration, Fig. 1, in a plate secured to the valve, which, when the latter is closed, almost completely obstructs access from and to the combustion chamber. It is, in fact, a sort of auxiliary valve which does not quite reach its seat. It acts in the same manner as a metallic screen, preventing the inflammation of the gas contained in the valve chamber. Besides, the valve chamber is insulated from the motor by joints of refractory material, and might, if need be, be provided with air-cooling flanges. The system promises a considerable lightening of motors, greater reliability of light motors, greater fuel economy and the removal of troubles with cooling apparatus and cylinder oils.—*La Vie Automobile,* June 11.

A spring suspension system by which much of the motion required of spring action is transformed from vertical motion, which shakes the occupant of the vehicle, into horizontal motion, has been tried in practice in Germany, and is shown in part in the accompanying illustration, Fig. 2. Unfortunately, the elements are omitted which would explain how the recoil of the spring is utilized or disposed of. Apparently the spring, which is suspended from *x* to *y*, must be a combined extension and compression spring mounted, possibly in telescoping tubes, under a tension corresponding to the normal weight of vehicle body and load. The system is mentioned as the Deussen Suspension. By its use the front and rear portions of the automobile frame are both shortened, and the wrought iron shapes which hold the bell levers are riveted to the frame ends. The helical spring is secured, as mentioned, to the upright arms of the bell levers, while the horizontal arms are shackled to the wheel axle in a manner the details of which are as yet withheld from publicity. When the wheel axle is pushed upward by an inequality in the road, the shock is transmitted through the shackles and the horizontal arms, *a—b,* to the bell-lever bolts and the upright arms, *a—c,* the latter spreading and extending the spring. By suitable choice of the lengths of the arms very considerable obstructions may be surmounted with very little raising or lowering of the vehicle body. At the trials it was noticed that very uneven ground produced some horizontal motion of the vehicle body, which was noticeable but not disagreeable to the occupants, while the vertical motion was much smaller than with any combination of leaf springs and pneumatic tires.—G. Wentz in *Der Motorwagen,* June 10.

Calculation of the dimensions and strength of valve springs on the basis of a graphic development of the velocity-curve produced by a given shape of the cam and an acceleration-curve developed from the velocity-curve, formed the difficult subject of a treatise by von Doblhoff, of which mention was recently made in these columns. As slight variations in the temper of valve springs, as well as the preferences of the designer with regard to cam shapes, would cover a considerable range, the treatise seemed to illustrate a design method remarkable for its refinement more than for its necessity. Hubert Schimpf, another German engineer, has taken up the gauntlet, however, and by analysis of his colleague's work finds errors in the graphical developments, and he designs a new acceleration-curve, from which he then proceeds to draw inferences with regard to what constitutes the most favorable form for cams, with a view to using springs of the smallest practicable tension as well as the other considerations relating to the timing of valve action. He arrives at the conclusion which empiric designers had already adopted, that neither the cam shape nor the strength of the springs, which depends upon the cam shape, may be calculated without a compromise between the requirements. In other words, a rapid and definite valve lift will involve a strong spring and increased wear of parts, while a noiseless valve action cannot be realized without sacrifice in the form of a more or less dragging valve lift and valve closing.—*Der Motorwagen,* June 10.

Among the many motor 'buses offered to the Paris General Omnibus Company is one that employs neither gasoline, alcohol nor benzol as fuel. The Cazes, produced by a firm having made a specialty of stationary and kerosene motors, has its own coal-gas producing plant, and consumes low grade coal gas as fuel. In accordance with the new requirements of the Paris municipality, it is a single deck omnibus with first and second-class places and a rear entrance on which two passengers can be carried. The motor is forward, under a bonnet, unlike the present vehicles, which have their power plants under the driver's feet. Special attention has been paid to suspension and the abolition of vibration, and with this object in view the 'bus is mounted on long semi-elliptic springs, and in addition has pneumatic shock absorbers attached to the forward dumb irons and linked up to the front axle just below the spring clips by means of a rod. This is contrary to usual practice, in which the springs have been connected up direct to the shock absorbers. The front springs, too, are shackled at their forward end in a manner first introduced by the De Dion Bouton Company. Although the 'bus is being used as a demonstration vehicle with the hope of convincing the company of its superiority over all other makes, the manufacturers have very little to say about its distinctive features. They declare that its gas-producing plant, carried by the side of the driver, allows this vehicle to be run at a fuel cost of 9 cents a kilometer, compared with 55 cents for a similar vehicle employing gasoline. In comparing such figures it is necessary to take into account the fact that gasoline in France costs from 38 to 40 cents a gallon, and that there is in addition a tax of practically 18 cents on all that is consumed in the city of Paris. Under such conditions the operating company is closely concerned in finding an economical substitute for gasoline, and it is here that the Cazes Company believe they have an advantage.

The mechanical features of the omnibus are four separate cylinders, water cooled by pump circulation, and only differing from the standard gasoline motor by the nature of the intake piping. Ignition is by high tension magneto. A cone clutch is employed, a four-speed gear box is fitted, and final drive is taken to the rear axle by side chains contained in oil-tight metal cases.—W. F. Bradley.

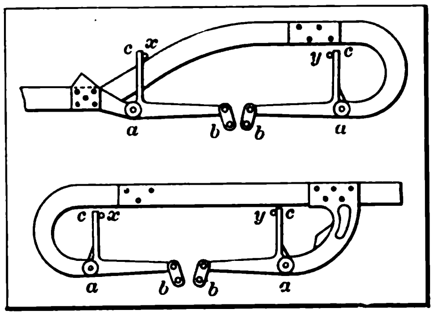

Fig. 2—Diagram of Deussen Suspension

It rests with automobile engineers to supply the scientific methods which may be required in the development of motor travel through the atmosphere, since the engineering talent specifically engaged in aviation is too busy with the fundamental problem to pay much attention to refinements not directly connected with design. The haphazard planning of aviation meets without reference to the science of meteorology, which might safeguard the success of these trials and exhibitions, grates on the trained sense which loves to fit means to ends with some accuracy. And, on the other hand, it has already been proven that the science of the weather has much to gain by applying itself and its resources, heretofore largely restricted to the laboratory, to the very definite determinations and forecasts which aviators will so greatly appreciate. Among the first cares is the devising of really suitable instruments for measuring the velocity of the wind at various altitudes. At the recent meet at Lyons the assistance of André, the director of the Lyons Observatory, was secured, and weather reports announcing atmospheric movements from the surrounding territory were received twice a day, and ingenious instruments were erected, one of which indicated the velocity of the wind by sound signals. A description of the instruments is supplied.—*Revue de l'Automobile Club du Rhône.*

Studies in Aviation Theory and Practice

By MARIUS C. KRARUP

STABILITY for aeroplanes, as has been shown in previous installments, is one of the two principal elements which must be materialized in aeroplane design in order to secure and maintain equilibrium, the other being control of the relative positions of the supporting planes through the actions of the aviator. An excess of stability would render control impossible or impracticable. For example, if stability sets up a resistance of 100 pounds against a deviation of 70 degrees from the normal horizontal poise of the machine, a control action meant to cause such a deviation would be required to overcome this resistance of 100 pounds, before it could become effective. If the deviation were to be accomplished in one second, as might easily be required for safety in avoiding collision with another aeroplane, treetops or any other obstruction, the effort of overcoming the resistance would have to be concentrated in the same short period, and this would tax the aviator too heavily. Laterally the stability can perhaps be allowed to be more pronounced, because centrifugality will help the aviator to produce the canting of the machine, which is necessary for holding one's course at a turn in horizontal direction. And departures from lateral horizontally is not otherwise required for travel. These simple considerations show at once that the stability which is secured by locating the center of gravity far below the planes may be bought too dearly. When inertia enters as a factor, as at starts, stops, retardations and accelerations, a very low location of the center of gravity may even actually contribute to loss of equilibrium, as the weighty bottom portions will tend to swing around the more resistant and lighter areas, or the reverse. Stability, as distinguished from equilibrium by control, evidently differs greatly from the same property in boats. It may not be built into the aeroplane in any desired degree, but consists at its best in a certain proportionateness between the weight distribution and the area distribution, and must be figured out and tried out in practice with due regard to all the various things which can happen to an aeroplane, with motor going and with motor stalled, with headwind, sidewind and wind from below or above. It must be proportioned with some reference to the muscular efforts which an aviator can apply and with some reference, too, to the range of control action which the aviator has at his command. The accompanying vignette, for example, tends strongly to prove that lateral stability is much too weakly developed in the ordinary biplane, in which the means for preserving lateral equilibrium by control action do not exist except in slight degree in connection with steering. In the Voisin biplane, shown in the reproduction, the lateral equilibrium is further endangered by the vertical partitions characteristic of this type, while the concentration of weight in the central part of the machine, it is believed, also minimizes the resistance to teetering of the structure.

An objection to this view has been offered to the effect that, even if weights were distributed more evenly along the level of the lower plane, as in the Wright machine, one-half of this weight would be tipped down while the other half was tipped up, and that the result, so far as the lateral balance is concerned, should be the same as with the weight all in the center. In a recent discussion on this point it was brought out, against this construction, that the machine is normally speeding forward and the planes are exerting a considerable pressure downwardly against a stratum of air which is condensed or formed into eddies, while the atmosphere above the planes is correspondingly or at least in some degree rarefied. Also, that there is seldom question of an absolutely one-sided impulsion from the wind. If a gust tends to lift one side of the machine, it will practically always also tend to lift the other side, though with less force. Finally, that the planes intrinsically offer less resistance against upward motion than against downward motion, owing to their shape. In the balancing of the forces acting to upset the machine laterally, the turning axis will therefore not be in the longitudinal axis of the machine, but nearer to the end farthest from the disturbing force, and weight will have to be lifted, not only turned around an axis. As these considerations seem to suggest themselves in connection with the subject, they are here mentioned, but, figuring the matter out with a diagram, only the last argument seems to maintain its force, and it only because the designer who places all weighty portions in the middle is practically compelled to place some of them higher than the floor of the lower plane and higher than he would be enabled to place them by using more "floor space," and as a result the center of gravity is therefore almost of necessity higher in the machine whose working parts are concentrated in the middle than in another in which these parts are spread more widely apart laterally. The important point seems to be that there can be no valid objection to the spreading of the weights, and that the accidents frequently befalling aeroplanes, as instanced in the illustration, seem to indicate that additional stability is required, at least so long as the means for preserving lateral equilibrium by control action are almost wholly lacking, and that one of the methods for securing increased stability consists in lowering the center of gravity, by spreading these parts out more than is usually done, while yet keeping the working parts inside of the general contours of the machine.

But it must be remembered, of course, that lowering of the center of gravity is less unobjectionable for the fore-and-aft equilibrium than for the lateral balance, and it may possibly be found that better means exist for avoiding lateral falls. Among the available means to this end, and relating to stability rather than to control, are pointed wings (planes), wings turned up at the ends and wings with elastic portions which ride easy over the "bumps in the air."

As equilibrium must depend upon a compromise between burdensome control and clumsy stability, and stability can probably not be obtained, in whatever degree shall finally be found desirable, without some sacrifice of sustentation, it is scarcely possible to do more than to mention the factors involved and the expedients at command, while the trained judgment of each individual designer, which must after all be supreme in matters which are beyond all quantitative figuring, must decide how much to concede to a low center of gravity, how much to pointed wings or wings at an angle or to the provision of resilient surfaces. As generalities, even when unavoidable, make irksome reading, the writer proposes to prevent drawings in a subsequent issue of an aeroplane in which his individual judgment on the subject, as well as the other connected subjects relating to sustentation, control, propulsion and materials, is exemplified.

In connection with lateral stability in the aeroplanes of current design, a matter relating to the maintenance of lateral balance may here be mentioned, though it relates to control rather than to built-in, automatic stability against lateral disturbance. For obviating a lateral fall the present day aviator depends almost wholly on speed, which is a control factor, but the adroit ones among the aviators, when threatened with a fall to the right, turn to the right—like a bicycle rider does under similar circumstances—without using the steering rudder, however. That is, they warp the planes or turn the winglets (ailerons). By this action increased sustentation is produced on the side to which the machine is tipping, and less sustentation is at the same time produced on the opposite side. But it seems that the warp system has a considerable advantage over the winglet system with regard to the aviator's chance for saving himself by this means, for, while the winglets produce a certain amount of action, they do not affect the action of the main planes, which remains as the large constant in which the small variant loses much of its proportionate effect. Structurally an aeroplane built with the warp system should, therefore, have the superior lateral equilibrium, while in automatic stability the two types are about equal, neither of them having any adequate provisions, the stationary vertical planes with which they may be equipped having a steadying effect only in calm weather and within the range of security which is produced by speed, and depends upon this factor.

How far true stability depends upon the location of the center of gravity, and how far and in what manner it depends upon the location of the areas and their slant or direction, remains the principal question for discussion.

In the automatic stability of aeroplanes the following factors are involved: Weight, area, direction of areas, center of gravity or distribution of weight, distribution of areas, shapes of areas, propulsive force, location of the propulsive force (including its direction) and, finally, the largest and most disturbing factor, the wind, coming, as it may, from all imaginable directions, and varying in power in the most unforeseeable manner. In general, gravitation makes weighty portions lead in the earthward direction and makes the area portions trail above, provided these area portions are not turned on edge, but continue to offer a greater air resistance to the downward movement than the weighty portions. Momentum, which is a product of the propulsive force and the weight, makes weighty portions lead in the momentary direction of motion, and makes area portions trail. Propulsion divides air resistances equally around the axis of propulsion; that is, any plane vertical upon the axis divides the total air resistance against propulsion in equal halves. The wind makes area portions lead in the wind's direction, and the weighty portions trail, but may attack one part of the structure in one direction and another part at a different angle, and its peculiar action upon planes which are held obliquely to the wind's direction as well as all the modifications of the direction of its thrusts, as due to the shapes and angles of incidence of the areas which it attacks, must, of course, be considered. In designing an aeroplane so as to produce automatic stability, to whatever extent is practicable, all the factors and forces just referred to must be reconciled. Whether the machine is propelled by its power, or is gliding by gravitation, or is halted in its progress by a sudden wind, there must be a certain amount of progressive resistance against deviation from that poise of the machine in the atmosphere, which means safety. The only simplifying element in this maze seems to be the fortunate circumstance that the large movements of the atmosphere, which carry the machine out of its course, perhaps, with relation to things on fixed earth, need only be figured on in so far as they are resisted by the propulsive force, or by the gravitation utilized for propulsion in gliding. A few diagrams will illustrate the proportions and shapes which serve automatic stability, constantly with reference to the idea, however, that this property may be realized in aeroplanes only in limited degree, as absolute stability would defeat the purpose of the machine as a vehicle for transportation.

Rejuvenating the Old Automobile

By G. J. MERCER

PROCEEDING along the lines as laid down for the previous efforts in this direction, the old body is utilized in the new undertaking, and the fore-door is designed so as to conform to the general appearance of the body as a whole. Fig. 13 shows how the body will look when it is rebuilt, and the shape of the overhang of the dash in order that it will join with the door post, making a workmanlike and artistic job. Fig. 14 is a detail of the fore-door on the entrance side with dotted lines which will be serviceable to the body maker, and Fig. 15 shows the disposition of the side levers, and the modification which will have to be made to accommodate them, while Fig. 16 is a plan of the new work.

Illustrating a modern fore-door type of body as it would appear on a Locomobile "Thirty" automobile, giving all information required by a body maker, and showing how the car will appear when completed. In this case the side levers are disposed of so that the sliding gear lever comes inside and the emergency brake lever falls to the outside.

Glancing at Fig. 15, it will be observed that the quadrant comes low enough to permit of bringing the gear level inside, it being perfectly straight as shown in the dotted lines, but the emergency brake lever comes to the outside, and while it is straight for its whole distance, it is bent sharply at a point just above the quadrant, and the handle is far enough out so that the operator, when he grasps the same, will have room for the hand without scraping against the head of the door. In the construction of this body, a bent ash pillar *A* in one piece forms the framing around the door at the back and bottom, this piece terminates at *B*. It is fitted to the front of the seat and fastened to the same with screws, reinforced by plates or straps. A sufficient offset is given to compensate between the distance across the underbody and that at the bottom of the seat.

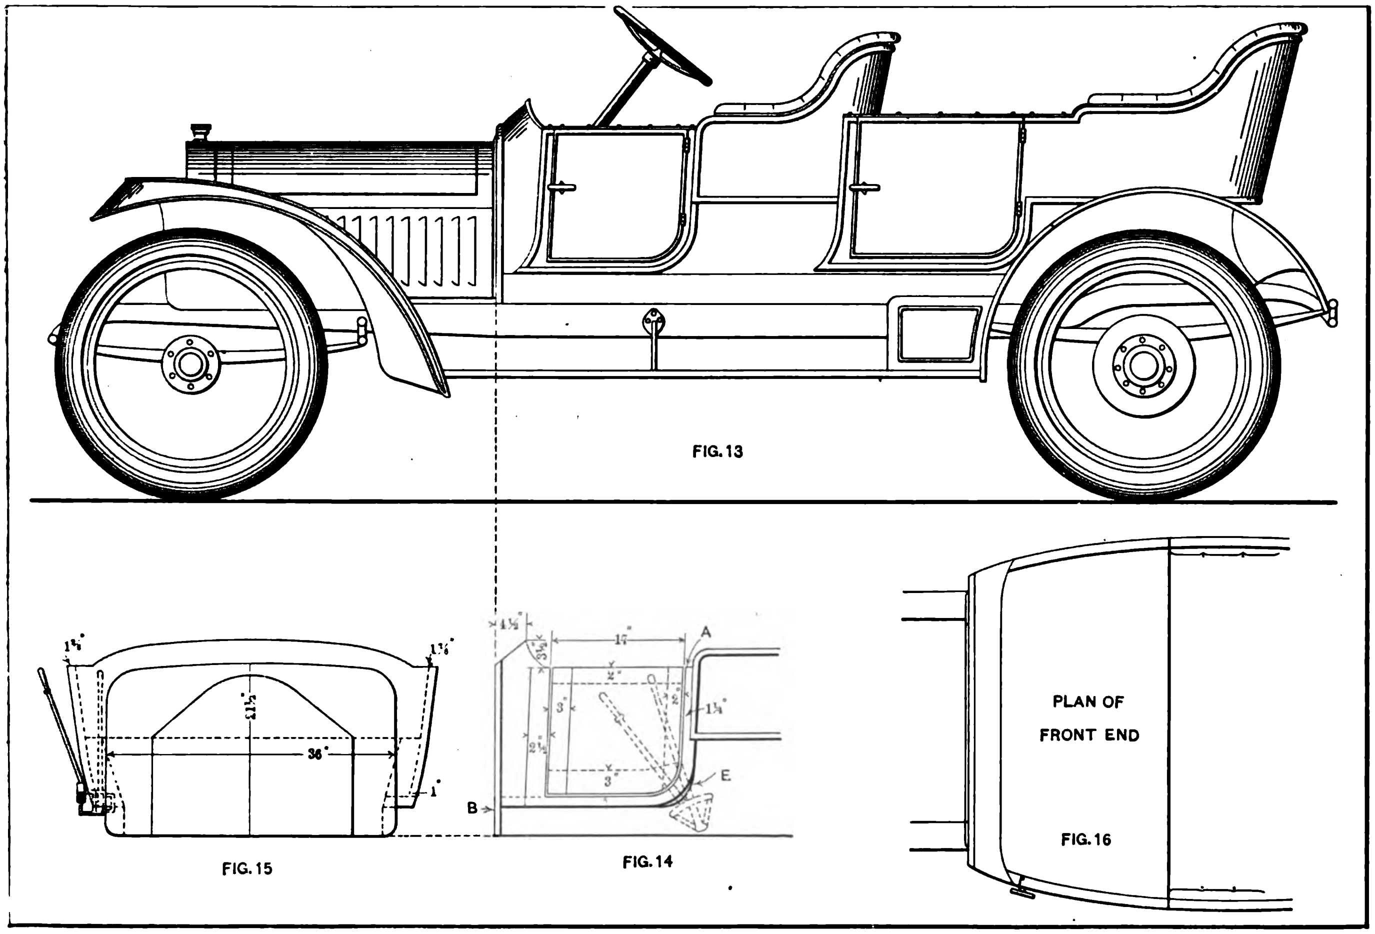

Fig. 13—Fore-door appearance of the Locomobile "Thirty" when the old body is changed over. Fig. 14—Detail of the new fore-door work. Fig. 15—Front elevation. Fig. 16—Plan

Forced Lubrication—Trend in English Practice

By R. K. MORCOM

(Fifth Installment)

CONCLUDING this paper on forced lubrication, tabulations of a statistical character are offered in order to show the methods in vogue in many of the best examples of foreign makes of automobiles, giving such detailed information as will permit the interested reader to judge for himself as to the practices abroad when reference is had to this important phase of automobile engineering. The conclusion is that lubrication is of the first importance, to be sure of a continuity of performance of the automobile from day to day, but also to influence in favor of a low cost of maintenance and a long life.

STATISTICAL TABLE SHOWING THE LUBRICATION METHODS IN

Name of Car	Adams	Ariel	Argyll	Alldays	Austin	Albion	B. S. A.
H.P.	16	31	15.8	10/12, 14/18, 20/25	15	16 and 24/30	15/20

Lost Motion Denotes Danger to the Autoist

Importance of properly fitting keys discussed; fetching up on a taper requires pressure; taper pins must be free from oil and fit in a reamed hole; some means for preventing levers from floating off shafts discussed; lamps deteriorate if they are not fastened to the brackets in a secure manner and methods are discussed.

LIFE as it relates to an automobile will be long or short, and the cost will accumulate, accordingly as the parts are kept in their proper relation, which involves inspection and adjustment as the occasion requires. The rotative members are protected if they are "booted" and a sufficiency of good lubricant is supplied, remembering, however, that the unctuousness of lubricating oil, when it departs, as it will in service, must be supplanted in a new supply of oil, considering, too, that the residuum (when unctuousness no longer obtains) has all the deteriorating charactertistics of a gummy mass, with a goodly sprinkling of abrasive material intermingled.

Taking it for granted that this phase of the automobile problem will receive its quota of attention, it remains for the autoist to inspect his car at frequent intervals, for the purpose of noting whether or not the linkages and levers are a tight and proper fit with the members to which they relate. Keys, if they are to measure in ability just sufficient to check up with the strength of the shaft after the keyway is cut, have to be quite small. On the other hand, if the keys are relatively large the shaft will be relatively weak. Designers, in view of the problem involved, are disposed to put the limit on the strength of the key, rather than to cut into the reserve strength of the shaft. Considering this wise provision, it is necessary to make sure that the keys are a proper fit, that they bear tightly on their sides and that they do not bear on the metal in the radial plane. In fitting keys, they are given a very slight taper, and when the workman is fully alive to the exigencies of key service he does the final fitting, utilizing Prussian blue and a dead smooth file, refitting sufficiently to make sure that the final driving of the key will fetch it up against the sides with a considerable amount of pressure, avoiding at the same time the damaging of the key, or the spline in which it fits.

If it requires a workman of no mean skill to properly fit a key so that it will stay in place and do its work with certainty, it goes without saying that an unskilled autoist is afforded an excellent opportunity to fail in his attempt to refit a key after it has been in service long enough to show signs of crushing, but it is not to be expected of an old key that it will serve any very good purpose if during inspection the autoist finds that the key is loose and he simply drives it home with a hammer with the expectation that this kind of key-fitting will be a near approximation to the character of the work which is done by a careful workman during the initial effort. When a key works loose in service and shows signs of wear it is time to dispose of it, and it will then be necessary to redress the keyways and fit in a new key. The fitting will have to be done with even greater care than originally, because the faces of the keyway will never be as good as they should be with a new car.

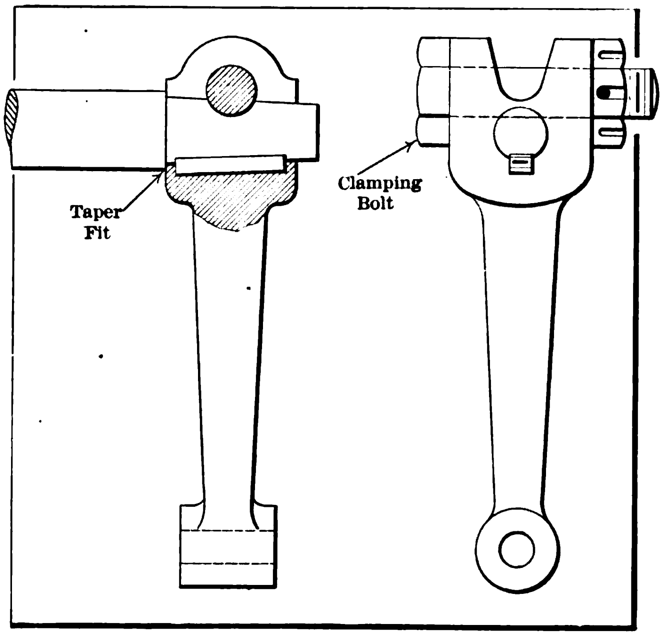

Fig. 1—Showing a lever with a key on a tapered shaft with a clamping bolt and locking nut

One way to maintain a tight relation of the key to its spline is shown in Fig. 1, which is of a lever on the end of a shaft with a taper fit of 3-16 of an inch to the foot, measuring from the center; in addition to the key, the hub of the lever, being split, is provided with a clamping bolt, and the bolt cuts the diameter of the tapered shaft where it passes through. The hub is a neat fit on the shaft, and the key is side-fitted with accuracy. The clamping bolt is then inserted, and the nut is set up until the clamping effect is sufficient for the purpose. The key is imbedded in the hub of the lever and the keyway is cut for the whole distance of the taper, parallel to the axis of the shaft. The clamping bolt has a locking nut, but the autoist must take into account the fact that the bolt will elongate in service, and that the nut ought to be taken up a little from time to time until the initial elongation of the bolt is supplanted by final rigidity.

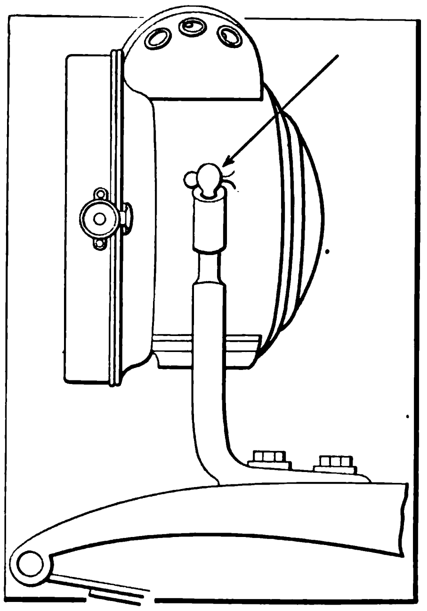

Fig. 2—Cotter pin over the washer on a lamp bracket placed to prevent the lamp from jarring loose

The clamping fit shown in Fig. 1 is on a round (tapered) shaft. In steering post work, however, it is not uncommon to use a square shank on the protruding end of the shaft. This idea is shown in Fig. 4. The square shaft is tapered and this character of fit, considering the four-sided shank, demands more attention than that which must be accorded the round shaft, because the latter may be reduced to its proper diameter by grinding methods. When the square shaft is properly sized, and the hub of the lever, with its broached hole, is "blued" and scraped to a neat fit, the clamping bolt is brought into play in precisely the same way as was described for Fig. 1, but there is just the same difficulty due to the tendency of the bolt to elongate in service, and the only way to overcome it is to take up on the locking nut as the occasion requires. The way to find out if a lever is loose on its shank is to take hold of the lever and see if it has any shake; there should be no sign of lost motion, but it rarely ever transpires that clamping bolts, if they are put under sufficient pressure initially, will continue in service without elongating, so that the autoist who finds his levers in a shaky condition should not be disappointed, but he is laying the foundation for a respectably sized repair bill if he fails to take action with reasonable promptness.

Fig. 3 shows a lever which is held on the shaft and prevented from rotating by a taper pin. It is a poor idea, nor can it be expected that the taper pin will hold out very long. With trouble of this sort, and it means trouble sooner or later, the average autoist finds himself in a quandary. When the old taper pin gives out he selects a nice, shiny new one, and he drives it into the hole with about the same force that the tup on a spile driver attacks the end of a spile. It is all to no purpose. No matter how much pressure is put on the taper pin it will not stay in place anyway unless the hole is re-reamed, to do which requires the proper use of a sharp reamer of the right size; even then, if the shaft is hardened, nothing good can come of it unless it is annealed before reaming. Finally, if a taper pin is to be regarded as efficacious, it must be cleaned thoroughly, removing all traces of oil, before it is inserted in the taper hole or else it will come out again; this is what lubricating oil is for. The walls of the holes serve as a bearing for the pin and if a lubricant is furnished there will be no metal-to-metal contact. In order to have metal-to-metal contact, which is what is wanted to keep a pin in place, the oil must be removed.

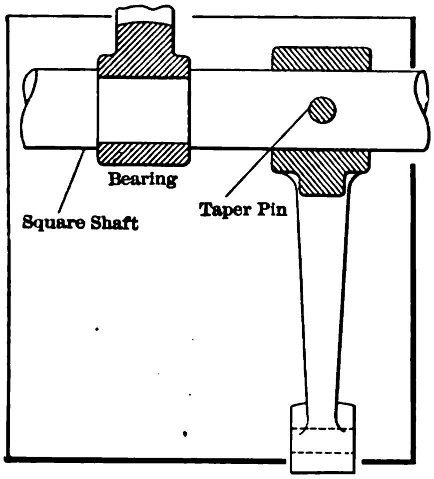

Fig. 3—Taper pin placed to prevent a lever from rotating on the shaft

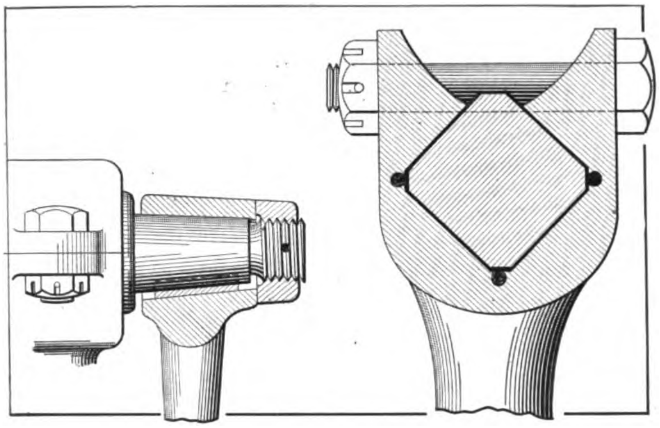

Fig. 4—Square shaft with a broached hole in a clamping lever hub and a bolt with a lock nut for clamping purposes

Lamps to give satisfaction, even if they are rightly designed, must be so installed that they will stay in place. This is not always the case, and Fig. 2 is used as an example to suggest one of the several ways which may be resorted to in order to hold the lamps in place. The brackets should be of steel and securely bolted to the frame.

Testing Steel—For Impact, Bending, Etc.

By BERTRAM BLOUNT, W. G. KIRKALDY and Capt. H. RIALL SANKEY.

(Third Installment)

Continuing the story of the tests as outlined in the last installment, the authors show the methods by which the tensile, chemical, and tensile-impact tests were carried out, and the results obtained. A diagrammatic sketch of the apparatus designed for the tensile-impact tests will assist the reader to a better understanding of the process.

THE following are some of the points attended to in the matter of selecting the position of test pieces.

When dealing with the steel plates, all test specimens were prepared lengthwise or in the direction of rolling, and it was not deemed necessary for the purposes of this investigation to include tests in the crosswise direction. As far as practicable the small specimens were taken from the same relative position, in order to minimize differences arising from difference in position. It was found impracticable to eliminate altogether effects due to position; for instance, the repeated bend specimens were taken near the skin surface, as would naturally be the case in ordinary workshop practice, and they then did not quite correspond in position with the small impact tensile and small static-tensile specimens, because the provision of suitable heads for holding necessitated the center or body of those specimens being located somewhat further in from the exterior surface.

Again, it should be noted that the standard-sized tensile specimens were made for the purpose of establishing the ordinary test data regarding the various types of steel and not for the purpose of comparison with the small specimens.

Tensile Tests

The tensile tests were carried out in the usual way and the standard test-pieces were made in accordance with the provisions of the British standard specifications. The small test pieces were 0.357 inch diameter with 2-inch gauge length. Mention need only be made as to the determination of the elastic stress. The procedure followed was that observed by the late Mr. David Kirkaldy, who, when commencing his testing operations, adopted the definition for the elastic stress as that where the rate of stretch ceases to be proportional to the load applied. This is determined by observing the rates of extension of the test-piece at regular increments of stress, and wherever the rate of extension increases the load is then noted.

As a matter of interest for this communication, the yield point, as evidenced by the drop of the steelyard of the testing machine, has been added; but Mr. Kirkaldy desires to point out that the practice at his testing laboratory has been steadfastly to combat the recognition of the "yield point." It is not

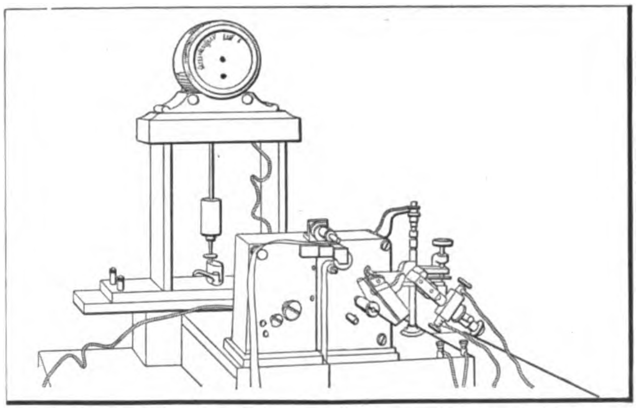

Fig. 4—Time recorder with half-second pendulum clock

a reliable criterion of the elastic limit, and he thinks that it ought to be discouraged. It is only during very recent years that he has been constrained to include this "yield point" in his official reports owing to the pressure put upon him by engineers insisting upon having it; as a *modus vivendi* he has therefore included it in his reports where wanted; but it has even then always been in conjunction with the determination of what he deems to be the elastic stress.

Chemical Tests

The following is a short description of the methods adopted for making the chemical tests which were carried out in Mr. Bertram Blount's laboratory:

Carbon, silicon, sulphur, phosphorus and manganese were determined in all the specimens, and in addition chromium and nickel in the specimen of high tensile steel intended for automobile parts. The methods of analysis employed were those usually accepted by steel chemists, and it is sufficient to indicate briefly which of the several methods recognized as reliable were preferred.

Carbon was determined by dissolution of the steel in potassium cupric chloride, its collection on asbestos in a tube closed with a perforated platinum cap and combustion in a quartz tube in a stream of purified air (not oxygen), the gases being passed over heated copper oxide.

Silicon, sulphur and phosphorus were determined by the methods given by Blair without modification.

Manganese was determined by Rothe's method, depending on the solubility of ferric chloride in ether for removing the bulk of the iron, followed by a basic acetate separation.

Nickel was estimated by a method depending on the formation of a double cyanide of nickel and potassium incompetent to dissolve silver iodide. A gravimetric method was also employed, consisting in removing the bulk of the iron as in the Rothe process, separating the manganese as dioxide and precipitating the nickel as sulphide in acetic acid solution, the small quantities of nickel remaining associated with the iron and manganese being separated by a basic acetate precipitation in the usual manner.

Chromium was determined by fusion of the product of the dissolution of the steel with sodium carbonate and potassium carbonate, the operation being repeated and the chromium reduced from its solution as chromate. and weighed as Cr_2O_3.

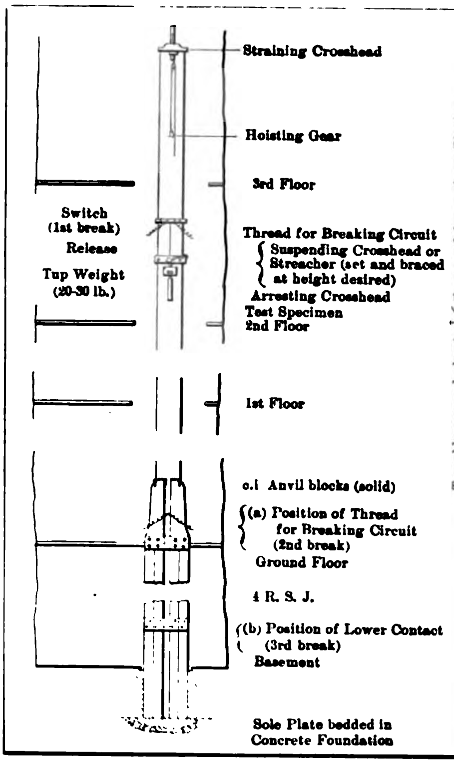

Fig. 2—Diagram of apparatus designed for impact-tensile tests

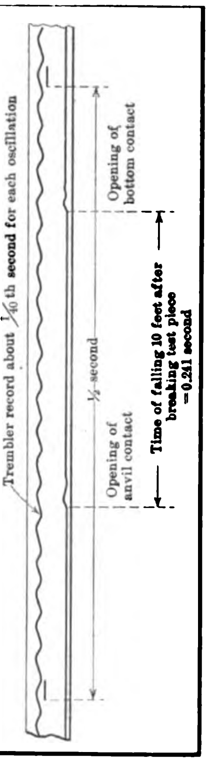

Fig. 5—Reproduction of record from time recorder

Tensile Tests

The general principles on which the machine used for these tests has been designed were referred to in the first installment. Fig. 2 gives a diagrammatic elevation of the machine and Figs. 3 and 4, Plate 1, some of its details. The anvil consists of a couple of castings weighing 400 pounds each, and securely bolted to four upright H-section steel columns, which in turn are bedded in concrete. The joint between the castings and the steel columns was machined and carefully fitted; the effective weight is 2,000 pounds and in this way an adequate mass has been given to the anvil. The edges of the casting are protected at the place where the blow from the tup has to be received by hard steel strips carefully bedded and securely bolted to the casting.

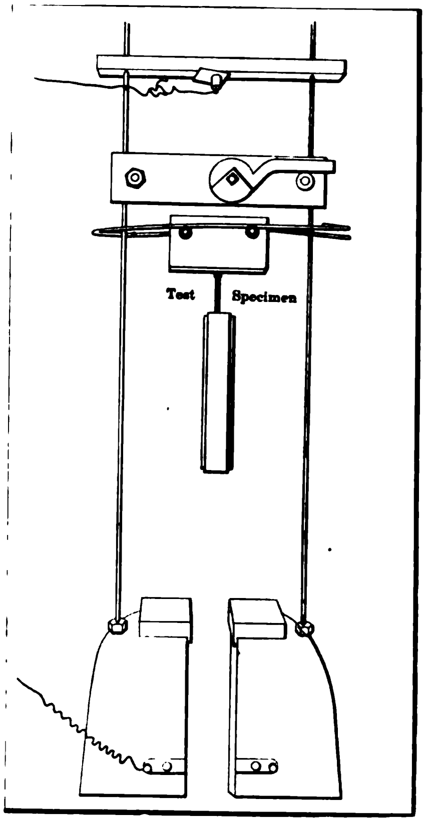

Fig. 3—Details of impact-tensile testing machine

The test piece connects together the "tup" and the arresting crosshead, the lower grip being fixed to the tup and the upper one to the crosshead, as shown in Figs. 2 and 3, and special care was taken in designing the ends of the test-pieces and the grip so that the line of pull would sensibly pass through the axis of the test-piece. The combination of crosshead, test-piece and tup is allowed to fall freely, there being no contact between the crosshead and the two wires shown in Fig. 2 on this page. and it will be seen that when the crosshead strikes the anvil its motion is suddenly arrested, but that none of its energy is communicated to the test-piece. The energy in the tup is, however, exerted on the test-piece and ruptures it, and with a given height of fall the weight of the tup is so chosen that there will be an energy excess to insure breaking the test-piece with one blow.

A stretcher is fixed to the two wires illustrated in Fig. 3, at any height desired, so that by connecting the crosshead to it any desired fall of the tup can be arranged for up to 40 feet. The connection of the crosshead to the stretcher is made by a suitable releasing catch. This catch is so arranged that the crosshead and the tup are instantaneously released without imparting any side motion to them—a more difficult thing to do than might at first sight appear. The tup was so designed that additional side pieces can be added to it. The smallest weight weighs 10 pounds and it can be increased to 20 pounds by steps of 2 pounds.

The energy applied to the test-piece at the moment of rupture can be accurately calculated from the height of fall, since it is a free fall, and as already stated the measurement of the remaining energy is determined from the velocity the tup has immediately after rupture. This measurement is made by observing the time interval between the breaking of two electric contacts, one placed immediately after rupturing the test-piece and the second 10 feet lower down. The energy absorbed by the breaking of the specimen is then determined.

Questions That Arise—General in Scope

Best way to locate cracks in cylinders; how to take automobile gasoline off of wearing apparel; reagents used in testing storage batteries; variations of the depression around carbureter nozzles; effect of such variations; functions of the intake manifold from the carbureter point of view; facility offered by tortuous passageways in the process of vaporization.

[152]—What is the best way to locate a crack in a cylinder if it is barely, if at all, discernible, especially if it is desired to determine how extended it is?

Moisten the surface of the metal with kerosene all around the suspected surface; rub off the oil and then chalk it over; the oil in the crack will exude and discolor the chalk: in this way the crack may be traced.

[153]—Would it not be good to know how to remove grease and other accumulations which are so prone to attack one's garments, especially when a repair by the roadside must be undertaken, and no provision is made for suitable over-garments of an appropriate character?

An old duster will protect the roadside repair man's clothing; if none is at hand and grease does find its way onto the garments, the cleaning process to employ depends upon the character of the cloth in the garment to be cleaned.

How to Clean Garments of Automobile Oil and Grease

Cotton cloth: rub with lard, then apply soap, in quantity to saponify the lard. Wash alternately with water and turpentine.

Woolen cloth: same as for cotton cloth.

Linen cloth: apply soap, or oil of turpentine, alternating with a stream of water under some pressure.

Silk fabric: apply lard, then soap, after which wash with benzine and water alternately; let the water fall from a height, or use a stream under some pressure.

Caution: Before proceeding to clean a delicate fabric, it will be a good precaution to try the process out on a sample of the same material, with a view to noting if there is some peculiarity of the fabric that will resist cleaning—it might be made worse.

[154]—What is the relation of nitrogen to oxygen in atmospheric air, under a pressure of one atmosphere, and at a temperature of 60 degrees Fahrenheit?

(*a*) To find the quantity of nitrogen, by volume, in atmospheric air, corresponding to one volume of oxygen, proceed as follows:

$$N = O \times 3.770992 \quad \ldots\ldots (1)$$

(*b*) To find the quantity of oxygen, by volume, corresponding to one volume of nitrogen, proceed as follows:

$$O = N \times 0.265182 \quad \ldots\ldots (2)$$

Volume changes with temperature; which must be considered.

[155]—What list of re-agents is used in storage battery work?

REAGENTS USED IN TESTING ELECTRIC STORAGE BATTERIES

Formula.	Reagents. Name.	To Make Solution, Proceed as Below.
$Ag\,N\,O_3$	Nitrate of silver.	1 part salt, 20 parts water, in orange colored bottle.
$K_3\,Fe\,Cy_6$	Potassium ferrocyanide, Red prussiate of potassium.	1 part salt, 12 parts water.
$K_4\,Fe\,Cy_6$	Potassium ferrocyanide, Yellow prussiate of potassium.	1 part salt, 12 parts water.
$N\,H_3$	Aqua ammonia, Ammonia water.	Purchase 16 degs. B., in glass-stoppered bottle.
K O H	Liquor potassæ.	Purchase ready for use, green glass bottle.
$Ca\,H_2\,O_2$	Hydrate of calcium and water, Lime water.	½ grain of lime to 1 oz. of water.
K I	Iodide of potassium.	1 part salt to 20 parts water.
$H_2\,S\,O_4$	Concentrated sulphuric acid.	Purchase 66 degs. B. sulphuric acid.
Cu	Copper filings.	Purchase test copper.
$Fe\,S\,O_4\,7\,Aq$	Green vitriol, Proto-sulphate of iron.	1 part salt, 8 parts water.
Au	Gold leaf.	Purchase as required.
H Cl	Muriatic acid, Hydrochloric acid.	Purchase concentrated acid in glass-stoppered bottle.
$Sn\,Cl_2$	Proto-chloride of tin.	1 part salt, 10 parts water.

[156]—What is the depression around the nozzle in the average carbureter as measured in ounces?

In view of the marked effect it has on the power of a motor, it should be maintained at the lowest possible limit. It is frequently estimated to be about 8 ounces per square inch. It has been found to exceed 32 ounces (2 pounds) per square inch.

[157]—What is the function of this depression?

The gasoline raises to near the opening of the nozzle, and the force which induces it to spray out is represented in the depression. This depression is below the atmosphere so that it is what is normally described as a partial vacuum. The difference between the pressure of the atmosphere and the depression (vacuum) represents the force which moves the gasoline out of the nozzle, more or less as a spray, into the air current as it is induced by displacement of the piston of the motor where the gasoline is taken up and more or less vaporized as it mingles with the inrushing air, thus producing the fuel mixture for the motor.

[158]—To what extent is vaporization attained around the nozzle?

It is probably true that vaporization starts at the instant the spray of gasoline is picked up by the air, and the intensity of this action depends upon the extent to which the pressure is lowered.

[159]—What are the influences for complete vaporization?

If the vaaporized gasoline is in spherical formation, or approximately so, the smaller the spheroids are, the more efficacious the result will be. Since vaporization is only possible if enough heat is delivered to the gasoline vapor to equal its latent heat of evaporation, it follows that there must be enough heat in the inrushing air to accomplish this end, but the spheroids must be small enough and offer sufficient surface, so that the heat transfer can be accomplished within the time available.

[160]—Does the length of the intake manifold affect this situation?

Since it is highly improbable that the gasoline, as it is sucked out of the nozzle, is in minutely subdivided particles, it follows that the heat-laden air will be retarded in the intermingling process and much more time is required in the process of vaporization than that available if the manifold is of small diameter and short. In view of these facts it is not out of place to consider that the manifold is but a part of the carbureter, and that it should be long enough to serve for the purpose of giving enough time to permit the air to give up its heat to the gasoline to form vapor. In other words, the intake manifold performs the function of a mixer.

[161]—Since the mixture will travel fast if the area of the manifold is restricted, why not make the manifold of large area, and in this way add to the period of time without having to add to the length of the manifold for the purpose of affording the requisite time to complete vaporization?

It is true that the larger area would afford its measure of compensation, but designers are debarred from resorting to this means for the reason that the rate of flame travel in the mixture must be below the rate of travel of the mixture, or, when the inlet valves open, flame from the combustion chamber will fire the inrushing mixture and will travel down to the carbureter, thus making what is commonly termed "popping in the carbureter."

[162]—Is it possible to prevent "popping in the carbureter" by designing the intake manifold with this end in view?

If the area of the intake manifold is sufficiently restricted, popping in the carbureter will be avoided, even though a spark plug be placed in the intake manifold and a spark applied, if the timing of the spark is such as to induce it after the intake valve opens.

What Side of the Road Should an Auto Take?

Editor THE AUTOMOBILE:

[2,317]—Will you please answer the following questions: When an auto driver wishes to pass a horse and buggy going the same way, which side of the road should the auto take? Under such circumstances, does the Ohio State Law oblige the driver of the horse to give the auto one-third of the road? A. E. E.

Lodi, Ohio.

When an automobile driver wishes to drive his car by a vehicle ahead, it is his duty to see that the road ahead is clear and pass the approaching vehicle on its left side. The law, whether or not there is a specific expression, is so construed that carelessness or recklessness must not be indulged in. Even if the law should provide for an allowance of one-third of the road for a horse-drawn vehicle, it does not necessarily follow that an automobile driver would be safe in passing the horse-drawn vehicle, either at a high speed or in such a way as to scare the horse; it would still be necessary to exercise "due caution."

Trouble is Tappet Rod Sticks

Editor THE AUTOMOBILE:

[2,318]—I have a two-cylinder motor of the opposed type, and it runs along very nicely excepting on occasions when the motor suddenly shuts down. I have gone over the timing, ignition system, carbureter, and pretty much everything, but the mysterious trouble above noted is still in the car. SUBSCRIBER.

Buffalo, N. Y.

Referring to Fig. 1, you will observe that the valve stem is offset from the tappet rod, and it is very likely that the guides are somewhat worn. The pressure comes on out of a straight line, and a certain amount of heat causes the lubricant in the guides to gum up. Your trouble, under the circumstances, is due to the sticking of the tappet rod, and you will be able to overcome it by using a stouter spring on the valve or hooking an auxiliary spring into an eye in the foot of the tappet head so that it will snap back and hug the face of the cam all the time instead of staying open, as shown.

Piston Rings Are Worn; Lost Compression

Editor THE AUTOMOBILE:

[2,319]—I have a two-cycle motor which works to my satisfaction for a part of the time; at other times I fail to get any good out of it at all, and I judge from indications that the compression is almost nil. W. A. L.

Harrisburg, Pa.

You will probably find that the piston rings are of stout section and lack flexibility. The ports are also wide, and as the rings sweep over the ports they tend to fall in; the result is that the corners of the rings are worn over the diameters which sweep the ports, and not being pinned, they float so that there is no compensation between them. A new set of well-made rings should help you out, although the remedy will be but partial if the cylinder bore is out of true. Regrinding the cylinders would be the further remedy. Fig. 2 is offered as a rough illustration of the idea here presented.

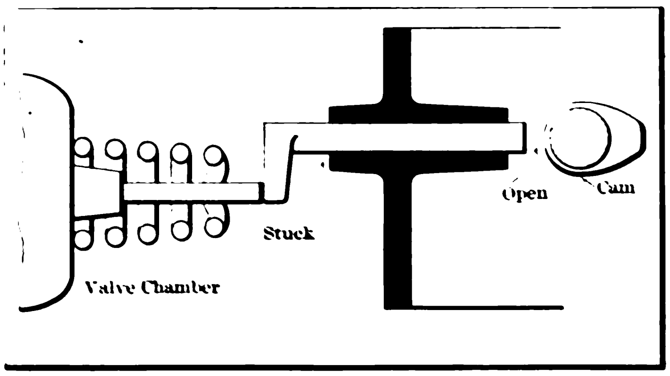

Fig. 1—Depicting offset tappet and showing how it sticks if it is not lubricated

Supply the Right Amount of Good Oil

Editor THE AUTOMOBILE:

[2,320]—My motor smokes every time I put oil in the crankcase, and continues to do so for upward of a half hour after I start out. The rough sketch enclosed shows how the oil is carried in the lower half of the crankbox, and the trouble is that I do not know when I put in enough oil; being afraid of lubricating trouble I am inclined to use an excess, but how am I to do otherwise with safety? READER.

Wheeling, Va.

Taking the liberty to revise your sketch as shown in Fig. 3, it is with the idea of putting a standpipe on the end of the drain cocks, which standpipe should be high enough so that it will project upwards within the case just the amount which will fix the desired oil level, so that the scoops on the ends of the connecting rods will dip into the oil each time they cross the bottom dwell point. Alongside of the drain cocks plugs are placed, one for each chamber, for the purpose of draining all the oil out of the wells at intervals in order that the quality of the lubricant may be kept up to a reasonable standard. It will be readily understood that after oil is put into the crankcase, if the drain-cocks are open, the excess of oil will drain out, leaving the exact right amount for working purposes.

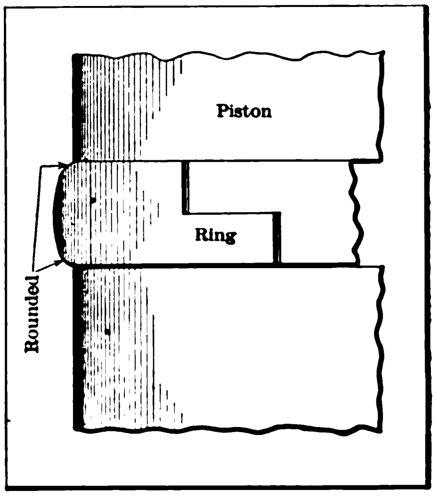

Fig. 2—Showing rounded corners of the piston rings due to the rigidity of design and wide ports

Turning Over Speed in Miles Per Hour

Editor The AUTOMOBILE:

[2,321]—I am much interested in your discussions in relation to the operation of automobiles, and I judge from talks which I have had with other beginners like myself that the question of safety on a curve is one which might be profitably exploited, and it ought to be of some assistance were one to know something of the border line of safety. Can you enlighten readers of "The Automobile" on this subject? K. A. C.

Bowling Green, Ky.

No two makes of automobiles perform precisely alike in this respect. Much depends upon the distribution of weight on the four wheels, and upon the center of gravity of the car as a whole. Assuming that the distribution is equal on the four wheels, and that the center of gravity is approximately in the plane of the axles, the curve, as shown in Fig. 4, will serve for the purpose. In this curve the turning arc is given in feet, as ordinates at the bottom of the chart, and the speeds at which the car will capsize are given as abscissa.

Discussion of Carbon Cracking Phenomenon

Editor THE AUTOMOBILE:

[2,322]—In your reply to letter No. 2,304, you mention free carbon as a second cause of sooting. I wonder if you are not perpetuating an error in this matter. I have experimented a great deal with oils since first driving an automobile and my experience goes to indicate that the presence of free carbon is a good sign rather than a bad one. This is so contrary to the accepted belief that some explanation is necessary. I early decided that the hotter the engine could be run the greater would be the economy, and possibly the power, and the less the radiating complications. The hot engine necessitates a high-test oil, and a hot engine will "crack" the fuel or oil much more rapidly than a cool one and, therefore, will soot up or carbonize more rapidly than a cool engine unless the heat is up to a still higher point where the carbon burns as it should and disappears. My water-cooled engines were not as hot as this but were hot enough to carbonize quickly.

My experience was, therefore, as follows: The low-test oil cracked, smoked, and sooted rapidly. The high-test oils remained on the cylinder walls and did not need to be fed in such a large amount. The low-test oils could be clear, almost white, and, therefore, probably free from "free carbon." The high-test oils were darker in color, which was quite manifestly due to "free carbon." When one takes a clear oil and mixes lamp-black with it to make it look like the darker oil, he is surprised at the small amount of lamp-black needed to effect the coloring. So small is the actual weight of black that it seems negligible. But the thought for your readers to keep in mind is that all mineral oil is a composition of hydrogen and carbon; that the large proportion of carbon is what adds the lubricating ability, and that the larger the proportion of combined carbon the better the lubricating ability generally; that gasolene and kerosene contain enough combined carbon to soot an engine quickly if "cracked," or separated, as they may readily try by turning the carbureter needle to get too much fuel and form a black smoke; that only as much fuel and oil should be used as the air will burn; that burning oil makes a very slow flame, and so yields very little power; that an excess of oil uses air which should be used by a proper amount of gasolene; that less of a high test oil will serve better than more of a low test oil; that the high test oil does not burn nor crack, as does the lower test oil. (This is readily proven by noting that an excess of gasolene makes a black smoke, whereas an excess of oil usually makes a blue vapor.)

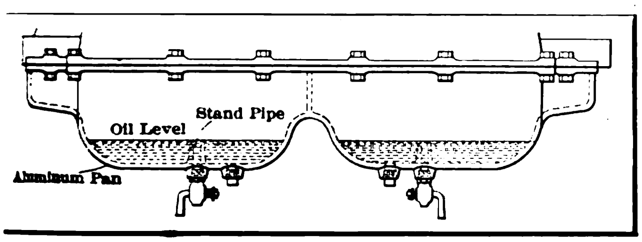

Fig. 3—Oil wells in the lower half of the case and method suggested to maintain the proper level

From the above I trust it will be seen that the other portions of your answers are correct, and that free carbon, instead of being an objectionable feature, may be evidence of a good oil, and therefore is not to be avoided.

The other thought in this connection is that engines may be run so hot as to burn the carbon deposits; carbon is simply fuel in solid form. That "red particle" of carbon which is supposed to cause preignition will burn and disappear if given sufficient free air for its combustion. If it does not get red enough to burn it does not get red enough to pre-ignite. The great trouble is that the driver, in striving to get maximum power, will feed all the fuel the air will take, and there is no free air left to burn this free carbon. The remedy for this is to use larger engines and have the gasolene needle where it can be reached so that when full power is not needed the mixture may be lean with plenty of free air. This not only burns the carbon but is economical and avoids odor.

Reading, Pa.

Temperature Must Favor the Boiling Point

Editor THE AUTOMOBILE:

[2,323]—Your reply to letter No. 2,309 indicates that you believe the temperature of the motor is an essential condition in spark starting. I am sure this is wrong. Gasoline will vaporize at ordinary temperatures and so will make an explosive mixture in the cylinder even when the engine is cool. The only requirements, then, are to have the piston where it can receive an impulse effectively and to have a mixture of proper quality, hot or cold, and to make a spark. If the engine is to start when cold the cylinder oil must be very thin, so the engine can turn easily. The mixture should be overfat. When the engine stops the hot walls will expand the charge and force out some of it past the rings; then, as the engine cools, pure air will be drawn in. If the charge is of proper economic proportions this air will reduce it so it will have but little power, but if overfat in the first place, the addition of air will make it more powerful, and taking out the spark plugs may be an advantage. From the above it will be seen that spark starting is not in line with economy, and, therefore, not to be considered as an unclouded good.

Your comments on the loss of heat in the air-cooled engine (page 1,138, issue June 23) seem to me incorrect. By using graphite for lubricant, and alcohol for fuel, it is possible to make an engine that need not be cooled worth mentioning; such an engine radiates the wall heat into the new charge and this heat is not lost. I use this simply as an illustration to show that the hotter the walls of an engine the less the heat loss. In the paper in question we must assume that the walls receive a fixed quantity of heat per impulse. To maintain the outer surface at 100 degrees centigrade requires a large amount of radiator surface for two reasons; the amount of heat to be dissipated is greater and the ability of the radiator is less, but if the walls can be worked at 200 degrees centigrade they will radiate more heat back into the new charges, and lose less by outward radiation; second, the radiating substance, being hotter, will part with its heat to the air doubly fast, and so need not have so large a surface. This is plainly shown by my experience with air-cooled engines having copper spines. Although of the 2-cycle type, they keep workably cool without the use of a fan, because the copper both carries the heat out quickly and parts with it to the air rapidly. There is a most noticeable difference in two engines of same size, one having cast-iron flanges, and the other having copper spines. The cast-iron flanges will be so cool one can feel them with the hand, without getting burned, but the copper spines will be sizzling hot, yet the iron cylinder will be overheated on a hard pull, while the copper spined one will be in fine working order.

CHAS. E. DURYEA.

Reading, Pa.

The temperature of boiling of automobile gasoline is all that is necessary—it may be low.

CINCINNATI, July 4—Reared upon the foundation principle of making the use of the automobile more pleasant to the residents of Cincinnati, the Automobile Club of Cincinnati has grown mightily; waxed strong in numbers and powerful in influence. Still in its infancy, measured in terms of time, the club has over 800 active members, each of whom is the owner of an automobile and an enthusiastic subscriber to the platform of the organization.

Like kindred bodies all over the country, the Automobile Club of Cincinnati is composed in large measure of the best and most influential citizens of its community. The roster of the club reads like a selected list of the leaders of the Ohio metropolis in all prominent lines of endeavor.

The club has been in existence only about two years in its present form, but it is accounted one of the important factors in the life of the city. No great project of a civic character is undertaken without consideration by the automobile club, owing to the fact that members of the motor organization are leaders in practically all the civic organizations of Cincinnati.

While the declaration of principles of the club contains only a single statement, its scope is so broad that every possible line of activity is included within its terms and the way the members attack the various problems touching upon the "rendering pleasant of the use of the automobile," is refreshing.

Without being in any sense a sporting organization, the club takes part in a wider program of sports than many clubs that are ostensibly devoted to that branch of motoring. The Tours and Runs Committee is one of the busiest subdivisions of the club and while a large part of its work is informal, nevertheless, it is particularly useful and efficient.

It is not a social organization, despite the fact that many of the leaders of Cincinnati's exclusive society belong among the [illegible]

It is not a political organization in any view, even though Cincinnatians are all politicians and the city is the home of the President and of the most prominent candidate to succeed Mr. Taft in that exalted office. Both Taft and Governor Harmon are enthusiastic automobilists and both are indirectly connected with the automobile club.

Tourists who have visited Cincinnati this season are impressed with the work of the club long before they reach the city. For miles around, practically every crossroad is decorated with signs showing directions and distances. Such a thing as police persecution may be said to be unknown and Col. Paul M. Milliken, Chief of Police, co-operates heartily with the club to protect motordom from injustice, while the club responds by firmly squelching any tendency on the part of the motorists to break the law. Mulct laws, either State or municipal, are nipped in the bud in a way that might seem mysterious if one did not understand the work of the Automobile Club of Cincinnati.

The Queen City is built like Rome, on seven hills, each of which presents a distinct problem to the owner of an automobile. It possesses much wealth and social prestige and as a consequence the proportional ownership of automobiles is very high. The city streets, drives and boulevards have a national reputation and the surrounding roads are excellent in the main. As a result, the pleasure of automobiling is splendidly augmented by natural conditions and with surprising speed the art of man is being applied to them. This work, directly or indirectly, may be laid at the door of the Automobile Club of Cincinnati, which is elaborately housed in the Gibson House, in Walnut street.

The club is managed by a Board of Governors consisting of fifteen members. The present board is composed of President Charles L. Bonifield, one of the leading surgeons of the United States; first vice-president, D. McKim Cook; second vice-president, G. W. Drach; secretary, Dr. L. S. Colter; treasurer, Louis J. Merkel; consulting engineer, E. J. Carpenter, and the directors, Dr. G. M. Allen, J. P. Orr, George W. Cleveland, William Perin, Dr. A. B. Heyl, Dr. C. C. Fihe, A. P. Streitman, E A. Conkling, Carl F. Streit and Charles W. Ireland.

These gentlemen represent the front rank in the vanguard of Cincinnati's progress along all lines of advancement. Finance, the professions and business interests of all kinds are included and the members who do not hold office are quite as prominent as those who do.

When any undertaking of the club needs to be financed the organization does not have to conduct street fairs or go begging. It dips into its own well-lined pocket and supplies the motive power. It holds monthly meetings and the President frequently calls special meetings of the membership, but the bulk of the club's work is done in committee-room. The difference between the operation of the club and some others is that "it gets action on everything it undertakes."

That does not mean that every project submitted to it is forced through successfully, but it does mean that the pigeonhole is not overworked.

In general way the activities of the club may be summed up under the following heads: First, in the erection of signboards throughout the territory over which the club presides; second, in the registration of chauffeurs; third, in favorable publicity; fourth, in controlling speeders and potential lawbreakers; fifth, in scrutinizing legislation; sixth, in boosting its membership; seventh, in conducting such functions as the annual outing of the orphans; eighth, in presenting entertainments that really entertain; ninth, in promoting sociability, and tenth, in insisting, quietly, effectively or truculently as the case may be, upon a square deal for the motorist.

These ten principles, all depending upon the first and greatest aim, that of "rendering the use of the automobile more pleasant," are only slightly different from the avowed purposes of nearly every other club in the land. The real difference lies in the way they are enforced and made effective.

Dr. A. B. Heyl, one of the directors of the club, is also secretary of the Ohio State Automobile Association and makes the Cincinnati Club his headquarters. This is a big advantage to the prestige of the club and a convenience to touring motorists. There is more independent action among Ohio motordom than there is in a big majority of similar State organizations. This is shown in numberless ways, but is particularly emphasized in the legislative situation.

A great motor speedway is being projected across the river from Cincinnati, and when the course is built and ready it will be only natural that the Automobile Club of Cincinnati will take a more prominent part in the sporting end of the work than it does at present. As it is, the club declines to be identified with race meetings that are founded upon the simple effort to gain dollars. As a matter of fact the money-making features of motoring do not appeal very strongly to the organization.

Coming Events in the Automobiling World

Jan. 7-14, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Automobile Manufacturers.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

LAST of the Glidden Tours is here, so it is claimed by those who make a point of prognosticating.

* * *

AERONAUTICAL performances, of which there are now plenty, tell a many-sided story; practicability is pictured in the whole situation. Some men claim that "Drednaughts" are no longer worth the price of metal it takes to build them, counting the value of the metal on a "scrap" basis. The main part of the story of the utility of the aeroplane is entirely overlooked; the great Western plains, with thousands of square miles of level country, alive with herds of cattle, running over with sheep, growing in agricultural importance, must be the near-future land of the "plane."

* * *

THE herdsman, with his "plane" will be able to do more and better work; it will cost him less than in the old way; he will be able to protect his cattle as he never could before, and the influences on the cost of beef will be so great that humanity will take very kindly to the "winged steed."

* * *

LOST motion, as it creeps into machinery, starting with the watch, passing through the reaper, locomotive, and no less in the automobile, represents the effect of time and service in the machines that are well cared for assuming that they are properly made. If good material is not used, or assuming that the character of the workmanship is poor, the extent of lost motion is more or less independent of time, and belongs in the land of speculation.

* * *

LUBRICATION, if it is properly cared for, if the good lubricant reaches the areas that are under pressure and the influence of relative motion as well, will do more to stave off old age than any other influence. Present practice abroad is given a measure of attention in THE AUTOMOBILE this week, and, while it may not be necessary for American designers to look about, the fact remains that it is not bad practice to keep abreast of the doings of others.

* * *

WHILE foreign technical papers pay rather too much attention to "sporting events" to suit the average American engineer, the fact remains that, of the 53 papers of this complexion which "go to press" regularly, some of them are up to a high standard, and the "abstracts" which appear weekly in THE AUTOMOBILE are culled for the purpose of affording to the American engineer a clear insight into the doings abroad, as they are depicted in the more reliable of these foreign papers.

* * *

INDIANAPOLIS has its Speedway events at sufficiently frequent intervals to keep before the public the fact that American-made automobiles are up to the scratch. It may not be generally appreciated that the hardest service that can be put upon an automobile is that due to speed. Weight is a factor, but this influence is only in direct proportion from the life-of-the-automobile point of view. Speed influences the life of a car quite differently; life is inversely proportional to the square of the speed. The Indianapolis Speedway is doing a great service for the automobile; it affords the speeding conditions necessary to bring out the staying qualities of the cars as no other test would do. Makers appreciate this fact and they owe much to the pioneers who had the hardihood to build the speedway.

* * *

STANDARDIZATION is a condition that cannot be present in automobiles unless it is first induced into the materials of which the automobiles are made. It is the purpose of the Society of Automobile Engineers to work on the material question until it succeeds in establishing a set of standards. The "Mechanical Branch" of the A. L. A. M., made good progress with this question, but inactivity for a couple of years has introduced "The frog in the well" plan which does not wholly solve the problem—bull-dog tenacity is the new idea.

* * *

BETWEEN the acts whipped into shape by the legislative "axe grinders" there are other features for the automobile to support. The latest idea was advanced by the men who champion the Long Island railroad in its campaign of extermination. It is now claimed that autoists, being more numerous than trains, should be required to protect the railroads by having "flagmen" at the grade crossings to warn trainmen.

S. A. E. Takes Lead in Standardization Work

Seamless steel tubing is being worked upon to reduce the number of sizes specified in every-day work; standard for square holes to be decided upon; broaches for square holes to be limited in number; valve-seat reamer angles will have attention; uniform standards for materials and tools will pay dividends; limits of tolerance to be defined.

HOWARD E. COFFIN, President of the Society of Automobile Engineers, states that the below copied letters, by H. S. White, of the Detroit Seamless Steel Tubes Company, and G. E. Merryweather, of the Motch and Merryweather Machine Company, hit the nail as squarely on the head as do any of the other communications which have been received by the society.

Up to the present time there has been an utter lack, upon the part of the engineers affiliated with the motor car, the accessories, or the raw material trades, of any general effort toward uniformity in the specifications of motor-car materials. This work cannot longer be neglected. It is of the most vital importance to the purchasing department, to the engineering department and to the business management of every concern whose interests are in any way connected with the motor-car industry.

The Society of Automobile Engineers is the only organization in existence at this time through whose channels the desired results may be obtained. The society is undertaking this work, and if given support in accordance with the importance of the end to be attained, will soon be able to show, in many directions, an improvements which may best be spelled in actual dollars and cents to the manufacturer and to the motor-car user.

The letters referred to are most worthy of careful reading, as being representative in every way of the general attitude of the machinery and raw material supply houses. Mr. Merryweather's letter is as follows:

CLEVELAND, O., June 21—Confirming recent conversation with President H. E. Coffin, I believe that the move of the Society of Automobile Engineers to standardize various material specifications, gauges and practices will be of the greatest value to the automobile manufacturers as well as to the material supply houses. Such work would also be of great value to the manufacturers of machine tools, and of small tools, and would greatly facilitate deliveries upon such goods and would decrease their cost to the manufacturer to a remarkable degree, because it would make it possible for the tool manufacturer to make up and carry such equipment in stock upon a commercial basis. A large percentage of this kind of work is now done to special order, because of infinitesimal differences in the specifications of every automobile manufacturer.

As only one of the many cases in point, take as an instance the broaching machine. If the automobile engineers would settle upon a standard for squared holes, giving distances across corners, and other dimensions in some definite ratio to the diameter of the shaft, and would tabulate this data for general use, it would mean an immense saving, both in time and money, over the present method of making each broach to special order, and one at a time.

Broaches for transmission gears, to be fitted upon shafts, with three or four keyways, should receive the same standardizing treatment as should those for squared holes. Valve-seat reamers, of two or three different angles of seat, could very well be standardized, and made up in a quantity commercial way in the various necessary diameters.

This same principle of recommended and tabulated standards could be carried out in innumerable directions to the very great benefit of the industry. Uniform standards in the specifications of materials, and tools, would insure immediate delivery to the manufacturer.

We believe that the work in this direction upon the part of the engineering organization is of very great importance and wish you every success along these lines.

(Signed) G. E. MERRYWEATHER.

Seamless Steel Tubes Demand Attention

DETROIT, June 18—Confirming by conversation with President H. E. Coffin yesterday in regard to standard sizes of seamless steel tubing for automobile construction we are preparing a card showing such standard sizes and will submit a rough draft of this card to you next week.

We cannot impress too strongly the importance, not only from the tube manufacturers' standpoint, but from the automobile manufacturers' view, of the necessity for the automobile manufacturers confining their orders to standard sizes. You can readily understand that if the tube manufacturers can work at their mills on standard sizes only, that they can increase their output and in that way make more prompt deliveries of material. Furthermore, if working only on standard sizes, the quality of the tube is bound to improve, as it goes without saying that when a workman turns out a regular product he is more inclined to become expert than if his energies are split up on a variation of sizes and gauges. On pick-up orders, some things that every automobile manufacturer is forced at times to purchase, if they have adopted a standard size, they can more readily secure what they want.

This matter was agitated some three years ago and at that time automobile manufacturers were ordering approximately 1,600 different sizes and gauges, but to-day there are only about 800 or 900 different sizes. The standard sizes listed to-day by the two manufacturers represents about 300 different sizes and gauges, and it would seem from the two manufacturers' point of view that a standard size could just as well be adopted as some odd size. After the adoption of the table of standard size in accordance with the rough draft we proposed to submit to you it would mean merely consulting a trade book or framed table in the drafting room, to find out what was a standard size, and then make their plans accordingly. We give below a memorandum of a few odd sizes which have been ordered recently:

(OD, outside diameter; ID, inside diameter.)

7-8 OD x 1-8 wall, 1 1-4 OD x 1 ID, 2 9-16 x .142 wall, 1 1-8 x 1-8 wall, 1 21-32 x 1 3-16 ID, 1 9-16 x 1 3-16 ID, 2 11-16 x 2 5-16 ID, 2 11-16 x 2 3-16 ID, 2 x 9-32 ID, 2 3-8 x 1 5-8 ID, 3 3-8 x 2 3-8 ID, 1 3-16 x 3-4 ID, 15-16 x 5-32 wall, and .855 x 7 gauge.

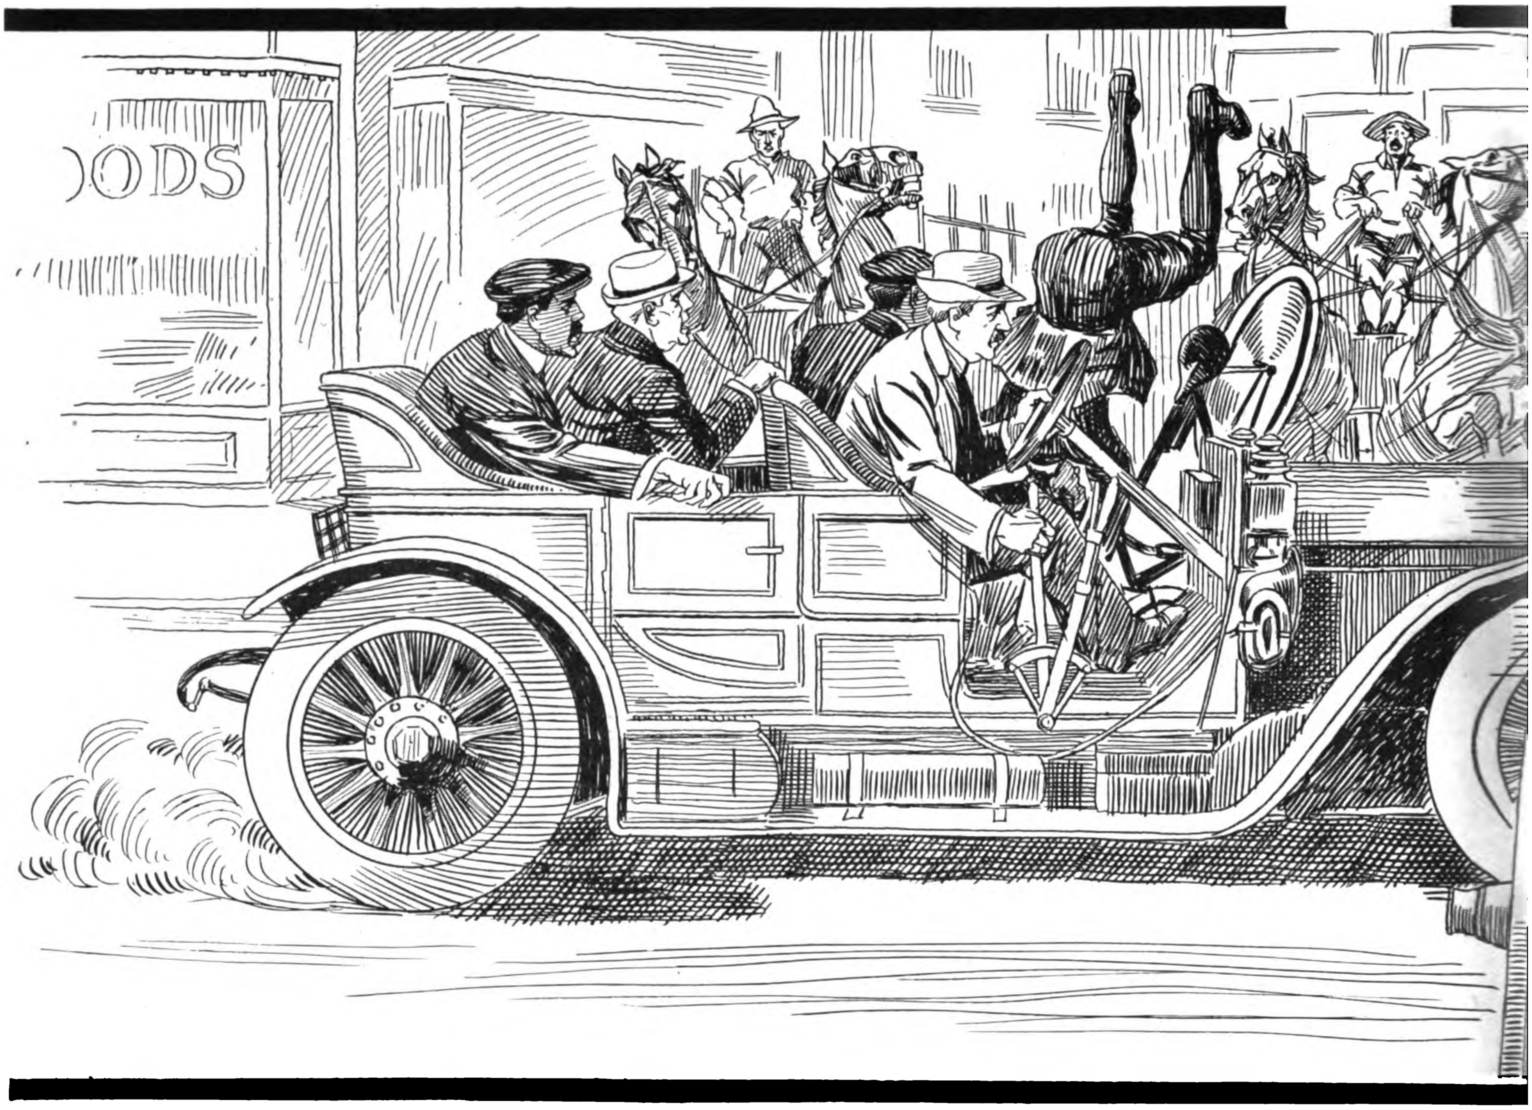
Any of these sizes mentioned above could have been changed by the automobile manufacturer in his original plans to a standard size. Take a tube ordered with a 1-8-inch wall, which size is not listed as a standard gauge, but 11 gauge could be used just as well. The 1-8 inch representes .125 inch and 11 gauge .120 inch.

On the question of variations, there seems to be a general opinion among automobile manufacturers that seamless tube is a finished product and can be furnished practically the same as a machine job. This is not the case and the automobile manufacturer should treat seamless tube as a raw product. This is particularly true where absolute accuracy is required, and in purchasing this material they should take this into consideration.

Tubes smaller than 2 inches OD will vary .005 inch minus to .005 inch plus on both the OD and ID. Tubes 2 inches and larger will vary from .010 inch minus to .010 inch plus on both OD and ID. The wall may vary not more than 10 per cent. of the specified thickness. Any tube which would meet with the above specifications would be passed by the tube mill inspector.

I would respectfully suggest that the Society of Automobile Engineers adopt as standard the sizes which will be shown on the card to be issued, and that the variations outlined above be also considered as standard by the society.

(Signed) H. S. WHITE.



SEEN IN NEW YORK: AUTOMOBILE ENTERS CONGESTED THOROUGHFARE FROM A

Long Island Railroad Regulating Automobile Traffic

JUST as it did thirteen years ago, Tally-ho Crossing of the Long Island Railroad at Valley Stream, took grisly death toll Sunday afternoon, when a swift train of the railroad crushed out the lives of Miss Jeanette P. Crawford and her sister, Miss Charlotte M. Crawford. Andrew Crawford, father of the dead girls, and himself a well-known manufacturer and sportsman, escaped death by a miracle, and Charles Neugebauer, chauffeur, was dangerously injured.

The grade crossing, like many of those of the Long Island Railroad, was inadequately protected. Despite the fact that the topography of the adjacent country renders it a constant peril, only a bell arrangement had been provided to warn travelers, and the survivors say that it was not rung.

In 1897 a tally-ho full of Sunday school pupils was run down at the identical spot where Sunday's accident occurred, and several of the children were ground to death.

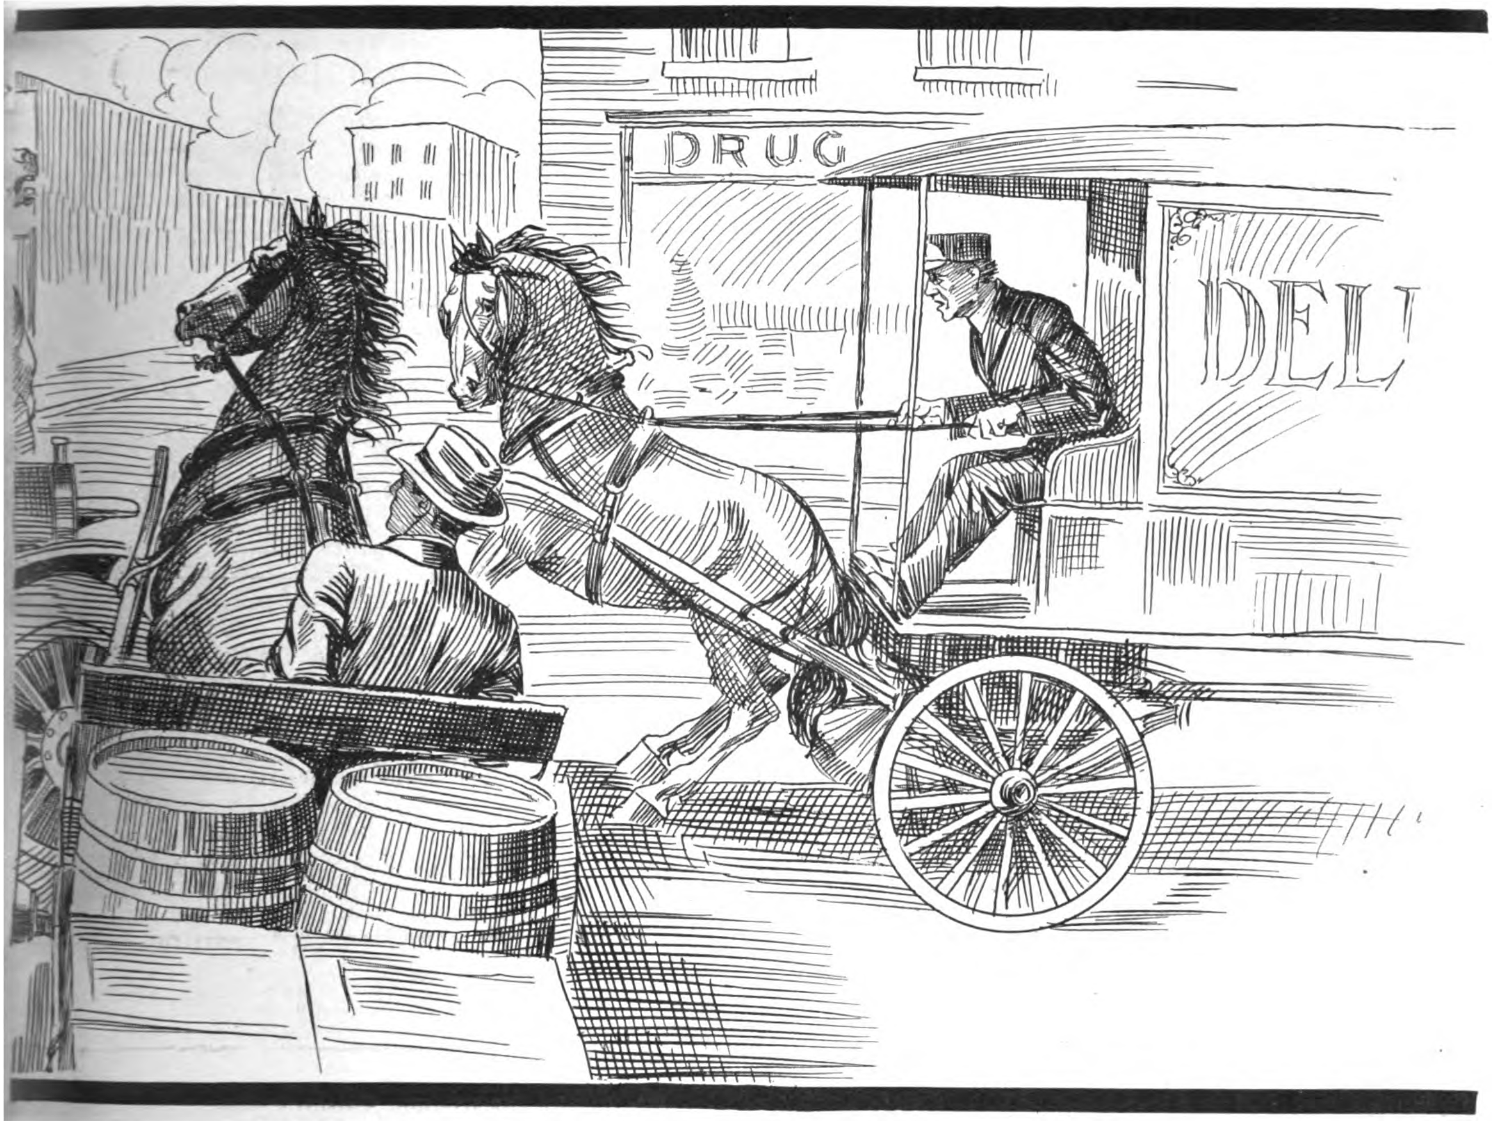
The Long Island Railroad Company is and has been a powerful influence in Long Island politics and economics. If one might lay a finger upon the most potent force that has been exerted to control and regulate automobiling on Long Island, that finger would rest not far from the headquarters of the Long Island Railroad Company.

It has always been sharply opposed to fast and reckless operation of the automobile and it has been whispered that moderate and legal motoring never met with much enthusiasm from the railroad management—at least as far as it applied strictly to the public.

In defence of the railroad company it has been said that if the Crawfords had not owned a motor car, the young women might be alive to-day. On the other hand, it has been pointed out that if the Sunday school children had not been taken out for their picnic in a tally-ho thirteen years ago, they might now be active members of the community, instead of sleeping on to eternity, under tear-wet mounds of green.

The position of the railroad company is entirely justified. If no pedestrians, carriages, tally-hos, automobiles or other conveyances of human beings ever cross the death-trap at Valley Stream, there can never be another fatal accident at that point unless, perchance, spreading rails or some mechanical defects in the trains cause a wreck. The company believes in enforcing the law—at least in the enforcement of some laws. Just why it should show favoritism about upholding those affecting the automobile in preference to those aimed at protecting the general public is a mystery.

In the meantime, unless the railroad company diverts a moiety of its energy now expended in "regulating" automobile traffic to the protection, or, better yet, the elimination of its numerous ghastly grade crossings, the people of the great State of New York can only look on, puzzled that the efforts of such a great corporation to prevent loss of life meet with no better success.



LATERAL AND IS RUN INTO BY A BICYCLE—DUE CAUTION WAS NOT OBSERVED

Chicago Motor Club Selects Elgin Race Dates

CHICAGO, July 4—So far this year no American road races have been run with the exception of a minor event in California, but the prospects are that this fall will see a series of brilliant contests. In a word, there will be a circuit starting in the West and winding up in the East, which will bring on five big road races within six weeks. This was assured when it was announced the latter part of the past week that the Chicago Motor Club had selected August 28 and 29 for its two days of road racing at Elgin.

While this matter has been in contemplation for some time, it was not until the night the Glidden tour finished in Chicago that the matter was brought to a head. At that time the Chicago Motor Club and the Elgin Automobile Road Racing Association signed a contract, the former to do the promoting of the races and the latter to finance them. The Elgin Automobile Road Racing Association is composed of prominent citizens of the town who are loyal enough to the city to give their time and money in advertising it in this manner. The Elginites have agreed to raise $20,000 to meet the financial requirements of the race.

This means the start of a circuit that will jump from here to Lowell, Mass., in case the Bay Staters decide to repeat their program of last year. After that there will be the Vanderbilt Cup race on the Long Island Motor Parkway on October 1. The Saturday following, October 8, there will be run at Philadelphia the third annual Fairmount Park road race. The circuit will wind up October 15 on the Long Island Motor Parkway with the running of the American Grand Prix.

The plans of the Chicago Motor Club at Elgin call for the running of three races simultaneously on August 28. These will be for the smaller classes. The 160-230 cars will run 144 miles and the winner will get $300 in cash besides the cup; the 230-300 class goes 180 miles with the same prizes up; while the 301-450 division travels 216 miles and the winner gets $400 cash and a cup. On Saturday the big race will take place. It will be for cars under 600 cubic inches and of a minimum weight of 2,300 pounds. The distance is set at 306 miles, and in addition to the trophy there will be three cash prizes of $1,000, $300 and $200 respectively for first, second and third.

Military protection will be secured for these races, and the course that is to be used will be the 9-mile circuit, which is exactly 1 mile west of the business center of the town. The course is declared to be a remarkably fast one, there being no roads crossing it, while the roads are particularly wide and the ditches shallow. There are only four turns in the course and one of these is a hairpin. At no place will it be necessary to shift a gear, unless perhaps at turning a corner. It is proposed, however, to bank these turns, and the chances are that the circuit will be good for 70 miles an hour by the time it is ready to race on.

Cobe Trophy Feature of "Fourth" at Indianapolis

(*Continued from page 2*)

on Burman, but the man in the Marquette-Buick was not to be denied, and dashed across the tape with the speed of a cannonball. He had covered the 40 miles in 31:46.02, 50 miles in 39:47.86, 80 miles in 64:24.48, 90 miles in 1:12:27.84 and 100 miles in 1:20:35.63, all of these new records for the 301-450 class. Dawson in the Marmon landed the 60-mile record in 48:15.29, and the 70-mile in 56:05.65.

Burman in the Buick Special carried off the honors in the mile time trials which opened the day's sport, showing 58:35 for the sprint, which was faster than Aitken in the National, Hearne in the Benz, Robertson in the Simplex, Wilcox in the Simplex, and Merz in the Empire could do. In the races that followed, Robertson in Herreshoff, Chevrolet in the Buick and Marquette-Buick, and Grant in the Alco were among the winners. The Greiner National and the Aitken National also scored, while the handicap was won by George Robertson in the Simplex. Aitken's victory was in the free-for-all, in which he defeated a choice field which included Robertson in a Simplex, Hearne in the Benz, Wilcox in the Simplex, Zengel in the Chadwick, and Burman in the Buick Special.

INDIANAPOLIS, July 4—It was indeed a well-satisfied throng that witnessed the wind-up of the three-day race meet on Monday, the Fourth of July, and a most befitting sane Fourth celebration it proved to be.

Event No. 2, a 10-mile race for cars in the 161-230 class, was put on first to try out the track. There were six starters in this race, including Sutcliffe in a Maytag, Kenyon' in a Fuller, Miller in a Warren-Detroit, Endicott in an E-M-F, L. Chevrolet in a Buick, and Burman in a Buick. Sutcliffe, Endicott, and Burman got away together in this event, but the end of the first lap found Chevrolet in the lead, with Burman about 50 yards behind him, with the rest stringing along about 100 yards behind him. The race was a romp for Chevrolet and for Burman, the former finishing first in 9:12.23, and the latter second.

Event No. 1 was next with three Herreshoff cars driven by Roberts, McCormick and Herreshoff as starters. It was a 5-mile event for stock-chassis cars of Class B, Division 1, having 161-cubic inches piston displacement or under. Roberts took the lead in this event and was ahead by about 200 yards at the end of the first lap, and at the finish he stretched the distance to about 300 yards, with Herreshoff second and McCormick a slow third. The time was 5:32.87.

Event No. 3 was a 5-mile race for stock-chassis cars with a piston displacement of 231-300 cubic inches. Seven cars lined up for the start in this event, with Fox in a Pope-Hartford, Moore in the Great Western, Davis in a Great Western, Cook in a Black Crow, Stinson in a Black Crow, Heineman in a Falcar, and Pearce in a Falcar. While these cars were lined up, and before the race was started, the Remy Trophy, and the Remy Grand Brassard, won in the 100-mile race Saturday, were presented to Robert Burman.

Pearce's Falcar got away first at the start, but Heineman immediately forged ahead and took the lead, while Moore killed his engine at the start and dropped out of the race. Heineman won in this event, with Pearce second, and Stinson third. The time was 4:44.31.

Cobe Trophy Was Then Competed For

At 3:10 fourteen cars lined up for the Cobe Trophy race, the big event of the afternoon, which was open to all stock-chassis cars having 600 cubic inches piston displacement or less. The distance was 200 miles. The fourteen starters included Wilcox in a National, Fox in a Pope-Hartford, Kincaid in a National, Aitken in a National, Cook in a Black Crow, Stinson in a Black Crow, Harvey in a National, Grant in an Alco, Harroun in a Marmon, Dawson in a Marmon, L. Chevrolet in a Marquette-Buick, Burman in a Marquette-Buick, A. Chevrolet in a Marquette-Buick, Pearce in a Falcar, and Wishard in a Mercedes-Simplex. A. Chevrolet in a Marquette-Buick led the field at the end of 10 miles, closely pursued by Burman and Kincaid. Burman led till the 180th mile, when the Dawson Marmon swung into the lead and was never headed.

Details of the Doings on July Fourth

Event 1, stock chassis cars, Class B, Division 1—160 cubic inches piston displacement and under. Distance, 5 miles

No.	Car	Driver	Time 2 1-2 Miles	Time 5 Miles
19	Herreshoff	Roberts	2:50.00	5:22.88
21	Herreshoff	Herreshoff	3:04.08	5:55.35
20	Herreshoff	McCormick	3:23.25	Too far behind for time

Event 2, stock cars, Class B, Division 2—161-230 cubic inches piston displacement. Distance, 10 miles

No.	Car	Driver	5 Miles	10 Miles
35	Buick	L. Chevrolet	4:46.43	9:12.23
36	Buick	Burman	4:48.88	9:21.77
26	E-M-F	H. Endicott	5:03.92	9:51.22
2	Maytag	Sutcliffe	5:03.49	9:51.55
5	Fuller	Schwitzer	5:18.73	10:17.86
24	Warren-Detroit	Miller	5:04.10	——

Event 3, stock chassis cars, Class B, Division 3—231-300 cubic inches piston displacement. Distane, 5 miles

No.	Car	Driver	2 1-2 Miles	5 Miles
44	Falcar	Heineman	2:30.56	4:44.31
45	Falcar	Pearce	2:37.68	4:55.45
17	Black Crow	Stinson	2:39.62	4:57.19
3	Pope-Hartford	Fox	2:45.85	5:31.53
15	Great Western	Davis	2:57.03	5:44.32
16	Black Crow	Cook	2:46.65	5:45.84

Event 4—Not run. Scratched from program

Event 5, stock chassis cars, Class E—Opened only to registered amateur drivers in accordance with definition of racing rules of the A. A. A. Distance, 5 miles

No.	Car	Driver	2 1-2 Miles	5 Miles
48	Mercedes	Wishard	2:17.30	4:21.34
12	National	Greiner	2:17.25	4:21.35
1	National	Tousey	2:27.12	4:54.82

Event 6, Cars Class D—Free-for-all open race. Open to all cars entered at the meet. Distance, 20 miles

No.	Car	Driver	5 Miles	10 Miles	15 Miles	20 Miles
22	Benz	Hearne	3:34.48	6:58.55	10:25.17	14:06.72
8	National	Aitken	3:39.97	7:01.17	10:35.29	14:18.37
43	Buick Special	Burman	3:36.10	7:03.79	11:00.97	15:39.17
32	Marmon	Harroun	4:04.16	7:53 62	11:44.22	16:13.96
18	Chadwick	Zengle	4:17.02	8:03.20	11:44.23	....
29	Stoddard-Dayton	Tripp	4:04.99	7:57.20	....	....

COBE TROPHY. DISTANCE 200 MILES. STOCK CHASSIS

Car No.	CAR	DRIVER	10 Miles	20 Miles	30 Miles	40 Miles	50 Miles	60 Miles	70 Miles	80 Miles

Will the Aeroplane Nullify the Dreadnought?

WHAT the effect of the aeroplane will be as a measure of military offence and defence was foreshadowed when Glenn Hammond Curtiss recently dropped fifteen out of twenty-two dummy bombs within the outline of a battleship, which was simulated by a series of flag-buoys at Keuka.

Time after time the aviator crossed the target from side to side, dropping pellets of lead from varying distances and heights in order to demonstrate the efficiency of the aeroplane as a military force.

The conditions of the test were hardly those that would be met with ordinarily in service, for the target was stationary and, naturally enough, made no effort at offence or defence. It was shown that at low elevations the aviator was able to drop the bombs with accuracy and at 300 and 400 feet heights they scored center shots every time. When Curtiss shot his flying machine up to 900 and 1,000 feet, his bomb practice was not so good.

His machine was specially equipped with canoe-floats and this part of his preparations for the test received a thorough try-out, as he found it necessary to descend abruptly during one stage of the experiment and landed gracefully upon the smooth surface of the water. The canoes sustained the aeroplane and the aviator suffered nothing worse than a slight wetting.

The news of the accomplishment of Curtiss sent a thrill of apprehension clear around the world. Every foreign capital, as well as Washington, was tensely interested. The significance of the feat was apparent to all; not so much from the simple fact that bombs could be dropped from an aeroplane under favorable conditions so that they would strike a mark of the same size as a $10,000,000 battleship at anchor, as it was the fear of what a few simple developments might bring forth. If it is now possible to land dummy bombs on the deck of a great Dreadnought, in natural course of development, it is not improbable that the aeroplane will soon be able to drop torpedoes carrying 100 pounds of the highest powered and most concentrated explosive upon a similar mark with equal or greater accuracy.

All naval authorities agree that if enough high explosive can be detonated upon the deck of any ship, the ship must be destroyed. Therefore, the perturbation over the achievement of Mr. Curtiss is acute all over the world.

The Austrian Government, which recently laid down four super-Dreadnoughts, was palpably shocked. Archduke Leopold Salvator, at Vienna, exclaimed that international law will have to prohibit the use of aeroplanes in naval warfare. Prof. Parseval, a distinguished German scientist, said that he believed that an elevation of 1,200 feet was sufficient to protect an aeroplane from the secondary battery of a battleship and that at this height the aeroplane would be able to land bombs all over the ship. Hiram Maxim and Thomas A. Edison declared that further development of the aeroplane along this line was only a little way in the future.

In the late Russo-Japanese war, when the Japanese battleship fleet was blockading Port Arthur, the ships traveling leisurely up and down the narrows within a comparatively short distance of the beleaguered city, half a dozen aeroplanes capable of swooping down from the fortress in the dead of the night and dropping 100 pounds of nitro-glycerine down the funnels of the battleships, would have proved a moral deterrent that might have changed the fortunes of war even though no practical trial of their prowess was attempted.

The past week has also seen a number of interesting trials of the aeroplane in more peaceful lines of endeavor. Mrs. William K. Vanderbilt, Jr., made a trip in a Farman biplane as a passenger of Clifford B. Harmon, over the course of the Garden City Club, New York.

On Saturday Mr. Harmon, under peculiarly favorable conditions of wind and weather, broke the world's record for sustained flight when he drove his immense biplane 125 miles in two hours and three and one-half minutes. The machine weighs slightly more than 1,000 pounds and is the same machine with which Louis Paulhan set the old mark at Los Angeles, when he flew one hour and fifty-eight minutes without descent. Mr. Harmon took a circular course, widening the swings as the flight grew longer. The air was still during most of the trial and the start and landing were without special incident. Mr. Harmon has planned several ambitious flights for the near future.

Charles K. Hamilton, the hero of the great inter-city flight between New York and Philadelphia, gave a remarkable exhibition of his mastery of the air in his home town, New Britain, Conn., Saturday. After a number of preliminary attempts, he arose perfectly, circled the city and turned up Main street, sailing from the city limits to City Hall.

Two Cars of Solar Lamps a Month

One of the instructive and interesting items of automobile activity is the monthly shipment of two carloads of Solar lamps from the manufacturers, the Badger Brass Manufacturing Company, to the Chalmers-Detroit Motor Car Company. Solar lamps are now used as part of the regular equipment of 85 per cent. of the high-grade American cars, according to statistics compiled by their makers. Aside from automobiles, these lamps are made for bicycles and motor boats of all kinds.

Great Western's Winning Climb

The showing of the Great Western "30" in the free-for-all event of the hill climbing contest held at Pittsburg, Indiana, recently, was specially creditable. The great Western only recently has essayed to capture laurels in races on the flat and up hills, and its performances have proved decidedly meritorious on all occasions.

In the event referred to, four Buicks, one Oakland and Ford competed unsuccessfully with the Indiana car.

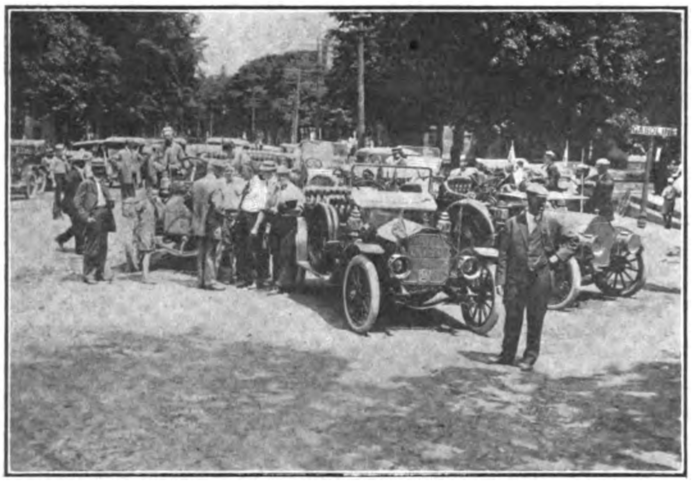
Highway Commissioners Prove Road Reliability

ROCHESTER, N. Y., July 4—With a business session in the Monroe County Court House, in Rochester, on Friday morning, the third semi-annual conference of the New York State Highway Commission with its Division Engineers, Section Superintendents, Division Supervisors, and the County Superintendents of Highways, came to a close.



Lima Noon Control: Enjoying scenery and surroundings

The business meeting was held largely for the purpose of discussing the conditions encountered by the members of this conference during the two days trip over the roads of five western counties.

Criticisms were made and views were interchanged as to the methods of conditioning the territory covered.

The principal criticism of the earth roads over which this trip was made was the fact that the many County Superintendents, overzealous to have the roads in fine shape, used poor judgment in scraping them and improving them just a few days before the run. This work served only to fill the center of the roads with inches of flour dust so as to make the travel rather strenuous.

On Thursday night a banquet was served on Ontario Beach at which more than 200 attended. One feature in connection with this run was that out of the eighty-one cars that started from Rochester, carrying nearly 400 persons, not a report of mechanical trouble of serious nature was made, and there were no accidents. So far as could be learned at the headquarters the only delays were due to tire trouble and they were noticeable by the smallness of their number. The cars which carried these road builders were almost entirely privately owned by members of the Automobile Club, of Rochester, and driven by amateur drivers, who did well.

As to the finality of this run the State Engineering Department is getting out a book which will contain a detailed report of all the observations made, together with photographs of the roads, drawings of crossings, bridges, etc., the idea being to perpetuate the good work, and economize cost.

Minnesota Enjoys Three-Day Meet

At the recent race meet staged on the Hamline track, near Minneapolis, a number of fast time trials and interesting contests were developed. The meeting extended over three days, and among the cars that made creditable showings were the following:

Cutting, which won a five-mile handicap event in 5:23.50; Marmon, which won a free-for-all in 5:43.80, defeating Oldfield, and two match races which were won by Cuttings.

Oldfield and Kerscher took part in the exhibition in a prominent way. The events were pulled off in regular order and with good success.

Auto Factory to Locate in Louisville

LOUISVILLE, July 4—Louisville will soon have its first automobile factory. It was announced last night by Berton B. Bales that the American Automobile Company, of which he is the president, will establish a factory in this city to cost approximately $125,000. Operations will begin January 1. The company is now manufacturing Jonz pleasure and commercial motor cars in its plant at Beatrice, Neb., and has orders on hand which will require nine months to fill. The plant in Louisville will be the main factory of the company.

Offices have been opened in this city and members of the company are negotiating for the purchase of a site. The company also has an office in Kansas City and is preparing to open a branch factory there. The American Automobile Company was organized in Arizona in May and has an authorized capital stock of $1,000,000. The stockholders at present comprise business men of Chicago, Kansas City and Louisville.

No water is required in cooling the engine and it is equipped with a two-cycle, vapor-cooled motor. At present the company is erecting a $20,000 extension at its Nebraska plant.

The Radcliff Motor Car Company, distributors of the Stevens-Duryea, has leased 916 South Third avenue and expects to occupy its new salesrooms about July 15. The Radcliff Motor Car Company is a newcomer in the local field.

The Reimers Motor Car Company has increased its capital stock from $10,000 to $50,000. The stock will be divided into $30,000 common and $20,000 preferred. The increase in capital was made to handle its new garage, which was formally opened to-day and to carry a larger stock of cars, supplies and parts. This company is the agent for the Reo and Haynes cars.

There were 81 cars at the noon control at Lima

Quaker Owners Buy a Club House

PHILADELPHIA, July 4—The large brownstone and brick residence at the northwest corner of Broad and Diamond streets, Philadelphia, occupying a lot 25 by 138 feet, and formerly owned by the late Senator Charles A. Porter, was bought Friday from the Porter estate by the Automobile Owners' Association for about $30,000, and will be altered into a club house. It is proposed to build a modern establishment.

Three New Companies and a Club Formed at Detroit

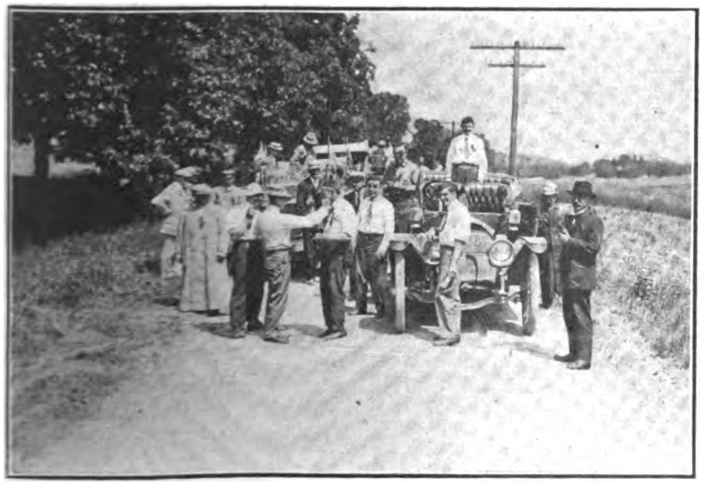
DETROIT, July 4—Three new companies and one new automobile club were announced in Detroit last week. The Exposition was the scene of one announcement, Wednesday night, when the first model H. & F. Electric was placed on exhibition there.

This car has just been completed by Frank D. Hovey and F. E. Foulke, the latter a Kansas City man of long automobile experience. The car has a number of new and different features, among which may be mentioned: a full aluminum body; light weight, 2,200 pounds; large carrying capacity, five to six persons; new battery construction, which yields 140-150 miles per charge; motor and rear axle in a unit. A company is now forming to manufacture the car, upon the construction of which the inventors have a number of patents. This company will, doubtless, be capitalized at $1,000,000. Four sites for the factory are under consideration, and so far has the matter progressed that part of the production for next year, 1,500 cars, has been contracted for. The present car sells for $3,000, but a lower priced model will also be built.

The Brush-Chicago Motor Company has incorporated for $12,000, while the Bower Roller Bearing Company, spoken of in last week's paper as about to remove here from Dayton, has incorporated as a Michigan concern for $225,000. The principal stockholder is given as Charles F. Lawson, Detroit.

At Ecorse the newly formed Jennings Motor Car Company is dickering with the town officials over a site for buildings, with fair prospects of coming to an amiable agreement shortly. This company has just been formed by influential Detroit business men, who wish to locate their factory near the city, but beyond the limit of city taxes.

It was announced from Wyandotte that the negotiations between the Seitz Motor Truck Company and the city had been satisfactorily closed and that the company would remove to the town at once. The town subscribed for $35,000 of the company's stock. J. H. Bishop and W. R. Beatty, representing the company, declared that the new plant would employ 500 men at the start, enlarging the force as necessity demanded.

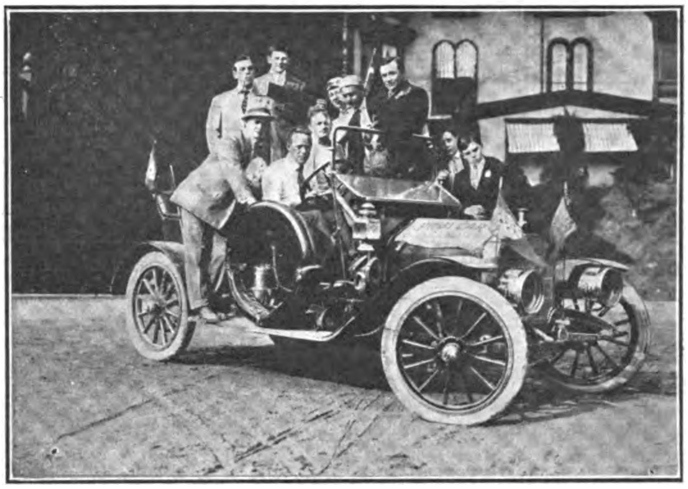


Inspecting McClintock's Cube Block Pavement near Charlotte

The new automobile club formed during the week will be named the Wolverine Automobile Club. A large membership is promised for the near future by the well-known and hustling men who comprise the organizers and first board of directors. The incorporators are: Messrs. Abbott, Brauns, Bryant, Collins, Gill, Gilmour, Mills, Radle and Trege.

During the past week the Hayes Mfg. Co. declared a stock dividend of 25 per cent., thus increasing the capital of the company to $500,000. This company declared a stock dividend last April of 200 per cent. The company now employs 1,100 men and does a business aggregating $1,125,000.

Great preparations are being made here for Elks' Week, which will begin July 11 and last about five days. During this period, the number of cars expected in the city is unusually large, so that extra provisions must be made to house them. Some 10,000 cars are expected.



Secretary Van Tuyler, of the Rochester Automobile Club, at the wheel of the Selden Pilot Car

During the past week, the activity of General Motors stock has been such as to cause much comment. The stock has risen steadily in the face of a lowering of prices in all other stocks, the rise in three days being from 118 to 125. One surmise made in financial circles and going the rounds now is that a stock dividend of 75 per cent. will be declared.

Wednesday night at the Pontchartrain there was given a rather remarkable affair when the representatives of the E-M-F Company and of the Studebaker Automobile Company sat down to a banquet, which was presided over by President Flanders of the former company. The Detroit men present were: W. E. Flanders, Robert Brownson, Frank E. Fisher, B. W. Twyman, Paul Smith, L. H. Rose, George E. Voglesong, Amos. F. White, David Hunt, Jr., L. Logie, H. T. Ewald, D. D. Byers, F. A. Wade, C. F. Garaghty, James E. Spencer, Frank Shaw, G. H. Kleinert, Clarence Booth, Max Wollering, Thomas Walburn, and James Heaslet.

The out-of-town guests were: George E. Keller, South Bend; C. F. Redden, New York city; W. J. Higgins, New York city; E. V. Stratton, Philadelphia; Frank Staley, Indianapolis; H. E. Westerdale, Chicago; A. J. Pray, Columbus; C. R. Dushiel, Milwaukee; H. T. Patton, Louisville; A. E. Thompson, Minneapolis; C. H. Woodruff, Minneapolis; Mr. Honeywell, Denver; L. F. Weaver, Portland, Ore.; C. N. Weaver, San Francisco; Mr. Tehaney, San Francisco; Mr. Williams, Pittsburg; Frank Shaw, Dallas, Tex.; Mr. Witmer, Kansas City; C. C. Snoke, South Bend; C. M. Barber, Oklahoma City; N. P. Berger, Omaha; T. L. Hausmann, St. Louis; Charles A. Malley, Boston; John A. Graham, Fargo, N. D.; E. L. Jacoby, Memphis, Tenn.; E. M. Greene, Syracuse; George W. Hanson, Atlanta; C. M. Love, Atlanta; B. S. Woolraven, Atlanta, and Dr. C. C. Root, Washington, D. C.

Auburn Hill Climb Is Postponed

Owing to lack of preparation, the hill climb of the Automobile Club of Auburn (N. Y.) scheduled to be held Independence Day was indefinitely postponed. It has been announced that the event will be presented later in the season.

National Wins St. Louis Star Trophy Run

ST. LOUIS, July 4—National car, No. 20, driven by Carl Merz, with a final score of 992, was declared the winner of the St. Louis Automobile Manufacturers and Dealers' Association's three-day reliability run for the *Star* trophy, after the technical committee had spent two days inspecting the cars which finished the trip. And, with one exception, each of the thirty contestants which started out from St. Louis June 28 on the run of 418.1 miles made the entire circle, although one was withdrawn before the finish and another was disqualified by the technical committee.

On the final score Oldsmobile, No. 5, driven by B. W. Olin, and Colmbia, 13, driven by Eddie Ernst, tied for second place with 991 each. Fourth place was awarded to Buick, No. 3, driven by Frank Delaney. Its score was 990. The three latter cars will receive certificates for their road scores.

While not one of the thirty cars showed a clean score after the technical examination, eight completed the circle with perfect road scores.

This was the first reliability run of more than one day ever given in St. Louis and the first of any kind to be given by the makers and dealers. One error alone probably is responsible for the fact that none of the cars made the trip without penalization. There was no penalty for reaching the various controls ahead of time and this turned the run into a sort of road race, many of the drivers hitting it up at a 25 and 30-mile rate when they found the road bed to their liking.

No.	Car	H. P.	Entrant	Driver	Final Scores

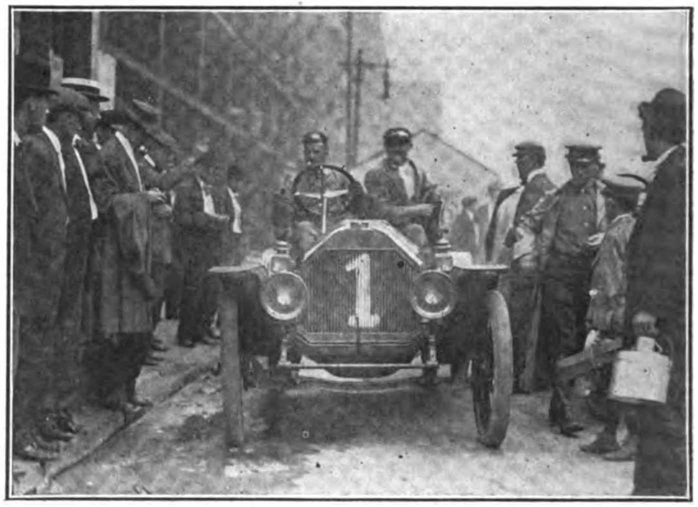
10	Rambler	54	Kingman Implement Co.	Will Smythe	(disqu'ed)
29	Stearns	30	Stearns Motor Car Co.	Koken	(disqualified)

No. 28, Moline, Driven by W. Von Steiger

A heavy rain fell the night previous to the starting of the run. The worst road conditions were on the first day out. After passing St. Charles, 40 miles of gumbo stretched ahead of the contestants. This had been softened by the heavy rain of the night before, and in some places the wheels sank almost to the hubs.

The first day's run was to Hannibal, with 45 minutes for lunch at Troy. This was the most eventful day of the trip. First, the crew of the Haynes car, No. 30, driven by A. A. Franklin, was arrested for a row with a farmer, who disputed the right of way, and the motor of the Haynes was stopped 125 minutes, with the result that the car was penalized 125 points. There also was a penalization for lateness. Rambler, No. 10, driven by William Smythe, got beyond the control of the driver just out of Eolia and rushed down a 20-foot embankment while making a speed of 40 miles an hour, hitting a telegraph pole and turning turtle. The four occupants, fortunately, landed in soft sod and none was seriously hurt. Marmon, No. 26, which was withdrawn, was compelled to limp in the last day from Macon on three cylinders. Stearns, No. 29, was disqualified after the finish when it was found that the brake had been wired to keep it in place.

On the second day's run the rods were fairly good, especially from Hannibal to Macon, where lunch was taken. The Buick pilot car driven by Crusoe, was compelled to halt owing to a broken torsion rod, but was soon repaired, and proceeded from Macon as confetti car. The Dorris car, in which were the officials, kept its position throughout the entire trip without any trouble. The second night control was Mexico. Up to this point, with the exceptions mentioned, everything had passed off smoothly.



Overland, No. 1, with C. E. Goldwaithe at the Wheel

The third day's run from Mexico to St. Louis was the fastest of the trip. The schedule set by the committee was an average of 20 miles an hour for cars of all classes. The road for two-thirds of the way led the contestants over rugged, mountainous roads. As a result much of the way the cars were required to run 25 to 30 miles an hour to make up for the time lost.

The Technical Committee was composed of George P. Dorris, of the Dorris Motor Car Company; Stewart McDonald, of the Moon Motor Car Company, and A. R. Van Antwerp, of the Van Automobile Company.

The cars which maintained perfect road scores were: Overland, No. 1; Buick, No. 3; Columbia, No. 13; Haynes, No. 19; National, No. 20; Inter-state, No. 21, and Moline, No. 28, and Oldsmobile, No. 5.

How the International License Works

PARIS, June 30—There is no need to obtain a driving and car license for every European country it is desired to visit. Slow, old-fashioned Europe has decided that all necessary safeguards can be taken by instituting one international license good for almost every country on this side of the Atlantic. It remains for the United States of America to insist that there shall be as many licenses as there are States.

The new arrangement, which is the outcome of an international conference held in Paris last year, provides for an international pass for both car and driver. The initial formalities are simple: Suppose the automobilist lands in Liverpool, he has his car examined by the local agent of the Motor Union, the Automobile Association, or the Royal Automobile Club. If it meets with the international requirements—and all modern cars do meet with these requirements—the owner is given a certificate stating his name and address, home registration, number of the car, a description of the car, maker's name, type of chassis and motor, the style of body and the weight in kilogrammes. If the car is registered in the United States, and carries an American number, the owner must place at the rear, above his home number, a black plate bearing the two letters U. S. If the car has been bought on landing in England, and is registered in that country, it must carry G. B.; if France is its country of origin and registration, it will carry the letter F.

Thus equipped, the car can be driven in Great Britain, France, Germany, Belgium, Italy, Monaco, Roumania, Servia, Austria, Hungary, Bulgaria, Spain, Greece, Montenegro, Portugal, and Russia, without any registration formalities whatever. In the same way the driver can undergo a practical examination and be provided with a license which will allow him to drive his car in all of the above countries for a period of twelve months without any formalities.

No. 20, National, Winner of the St. Louis "Star" Trophy

It is not necessary that a landing should be made in England in order to obtain this pass. If the automobilist disembarks at Havre the French Service des Mines will issue the necessary passes; if it is Italy or Germany the authorities charged with the supervision of automobiles, will grant the passes.

The new regulations do not in any way change the various customs formalities. In all protected countries it will be necessary to make the usual deposit on the car, or enter by the use of a triptych. Nor are the new licenses obligatory. If it is desired to go through the old formality of declaring the car, having the driver examined and changing the license tags at every frontier station, automobilists are at perfect liberty to do so. American automobilists possessing French cars and driving licenses, and intending to tour in this country only, have nothing to gain by applying for the international cereificate. As most Americans tour in three or four countries whenever they come to Europe, it is safe to declare that practically all of them will take advantage of this reform.

The only regrettable feature is that the United States has not thought fit to enter into this agreement. This would have made it possible for intending visitors to Europe to secure the international passes and affix the international license tag before leaving home. But if this were done, America would be under the obligation of allowing the Englishman, the Frenchman and the German to tour from New York to San Francisco with his home number and an international pass, while the native would have to comply with the automobile law of the different States he traverses. The object lesson is obvious.

Terms of Times-Post Flight Announced

Dates were set Tuesday for the aeroplane race to be given under the auspices of the New York *Times* and the Chicago Evening *Post* from Chicago to New York for a prize of $25,000. The race will start October 8 from the Windy City.

A résumé of the conditions follows: Entries may be made at any time after publication of the terms. There must be at least three competitors or no race. The start shall be 10 o'clock a. m., or as soon thereafter as may be, and shall be simultaneous, if possible. In case of bad weather the start may be postponed from day to day until October 15. Each entered machine must be in Chicago by October 3. The race must be finished within 168 hours from the start. Stops unlimited. Each entrant must have a verified record of one hour's continuous flight in Chicago between October 3 and 8. Repairs may be made en route, but aviators must finish in the same machines they make the start. If the start is simultaneous, the first machine that reaches the finish within the rules will be adjudged winner, but in case the entrants start at intervals due allowance will be made. A flight of equal or of greater length than the proposed course, prior to the race in this country, shall serve to invalidate its terms. The promoters of the event reserve the right to delegate the management of the affair to a recognized aeronautical society if such a course is deemed advisable.

Wright, Curtiss, Hamilton, Baldwin, Seymour, Mars, Willard, Harmon, Bergdoll, Farman, Sommer, Rolls, White, Paulhan and Rougier are mentioned as possible contestants.

Thirty, No. 16, Everitt, Frank Norris Driving

Regal "Plugger" Finishes 22,000 Miles

DETROIT, July 4—Having accomplished its "Around the Circle Tour" of 5,000 miles, the Regal "Plugger" reached home and received a hearty welcome. The route covered by the car on this tour was from Detroit to Boston, to New York, to Kansas City, Lincoln, Omaha, Minneapolis, Milwaukee, Chicago and back to Detroit. Besides following this itinerary, the "Plugger" made numerous side trips, participating in several endurance and roadability contests which swelled its mileage 1000 miles more than was originally contemplated.

Among the sporting events in which it took part en route was the run of the Quaker City Motor Club from Philadelphia to Atlantic City, where the car with its tonneau covered with tags and certificates of numberless cities and towns visited during its journeys that total over 22,000 miles, attracted much favorable comment from participants in the event and large crowds at both ends of the run.

Regal "Plugger" on its way back to Detroit after concluding 5000-mile circle tour

A fairly fast schedule was maintained throughout the whole tour and weather conditions were not regarded by the crew of the "Plugger." Several times the motor was stalled, owing to heavy going, and three times the car was capsized. The gumbo roads of Kansas, which were traversed during and after a series of unprecedented rainstorms, were the hardest problems for car and crew to solve.

The reception of the battle-scarred veteran was in the form of an automobile parade in which 100 cars participated. There was a brass band and a platoon of police and all the other things that go to make up a festal occasion. Mayor Breitmeyer, of Detroit, was the spokesman of the reception committee and said a few kind words of greeting from the entrance of the Hotel Pontchartrain.

The tour just ended began April 11, and from the outset almost to the conclusion, weather conditions were trying in the extreme. Several meteorological records were broken, particularly for rainfall in certain sections and for cold weather and bad roads throughout. One of the features of the work of the "Plugger" on all its tours is the presence of a tattered national banner. This flag was not always in such condition as it was when the car reached Detroit, but has been whipped and frayed out during the course of the numerous tours accomplished by the car. The "Plugger's" crew was: Lee Kuson, driver; George Franklin, Norman Taylor and Roy Dean.

Writing to THE AUTOMOBILE from Detroit, the latter, who was in charge of the tour of the Regal Plugger, has the following to say about road improvements noted upon the itinerary of about 6,000 miles:

Progressing east from Detroit, we began to see more of the macadam road as we got east of Cleveland. From there on to Boston one could readily realize that millions had been spent in making these highways what they are. Massachusetts, aside from the macadam, has found it advantageous also to use oil. This State exceeds all others in this respect.

West of the Mississippi the organization for the improvement of roads has not reached the perfection that prevails in the East, with the exception, I might say, of one State, Iowa. The great "River to River" road from Council Bluffs to Davenport, known as the Great White Sign Post road, is as fine a piece of highway as one would care to travel over. Every quarter of a mile, white sign posts have been placed all along it. When the road turns a hand pointing its direction stands ready to direct the wayfarer. Aside from this sign post road one finds nearly all the roads in good condition.

Good roads enthusiasts in Pennsylvania, especially those living in the district between Harrisburg and Greensburg, might learn an excellent lesson relative to the treatment of roads from what has been accomplished in Southern Indiana and Northern Kentucky, particularly as I found them between Louisville and Vincennes. The Harrisburg-Greensburg road leads over the Blue Ridge and Laurel Range of the Appalachian Mountains. Owing to the fact that McConnellsburg lies in a section that is inaccessible to the railroads, traffic over these ranges is naturally very heavy. But in spite of this fact it would hardly seem that the road question had been given any consideration whatever. For miles leading into McConnellsburg rocks and big stones are so strewn over the highways that it is almost impossible to drive an automobile through this section.

The Louisville-Vincennes road proves conclusively what can be done with such a thoroughfare as lies in the district of Pennsylvania of which I speak. The Hoosiers and Kentuckians fint it advantageous to take the stones from the highways, break them up with heavy crushers and place them back on the roads, with painstaking care relative to the grading, and they have succeeded in constructing an excellent highway. If the Pennsylvanians were to do the same the mountains lying about McConnellsburg could easily be negotiated wtih heavy auto trucks and exportation and importation carried on accordingly. They are attempting to overcome road traffic by constructing an aerial tramway from McConnellsburg to Fort Louden, the nearest railway station. But more could be accomplished were the highways to be put in a traveling condition for automobiles.

It is very interesting to observe the radical change that has taken place in the mind of the farmer relative to his attitude toward the automobile. Not over three years ago, in the majority of cases, the tiller of the soil was antagonistic. Seldom would one find him willing to extend a helping hand or mend his highways for the benefit of the automobile. Many were the occasions when we became stalled in the mud, and then we had to prevail on the generosity of the natives to aid us with their teams of horses and oxen. Compensation for the same was naturally always extended, but invariably it was refused, and almost always an apology was forthcoming on the part of the farmer for the condition of the

Mayor Breitmeyer, of Detroit, congratulating Lee Kuson, driver of "Regal Plugger" roads in his vicinity. Even though in some sections things have not reached a point where organizations are perfected to the point of thoroughly carrying out of good roads projects, the spirit is there and the future looks bright for better results.

Kansas, Nebraska and Iowa are reaping a certain amount of good through a law that allows each farmer fifty cents for dragging the road a distance of one mile and back. This puts the roads in fairly good condition. In some places, however, in order to obtain a good surface for carrying off the water, the matter has been overdone, and too much earth heaped in the middle of the highway. The result is that no one cares to travel on the center of this grade. The teamster or autoist prefers the side of the road, in which case one finds that for miles the center of the highway is grown up with grass, where if a little extra pains had been taken and a roller run over the center of the highway following the dragging it would have been sufficiently flattened down to induce the traveler to take the center of the road.

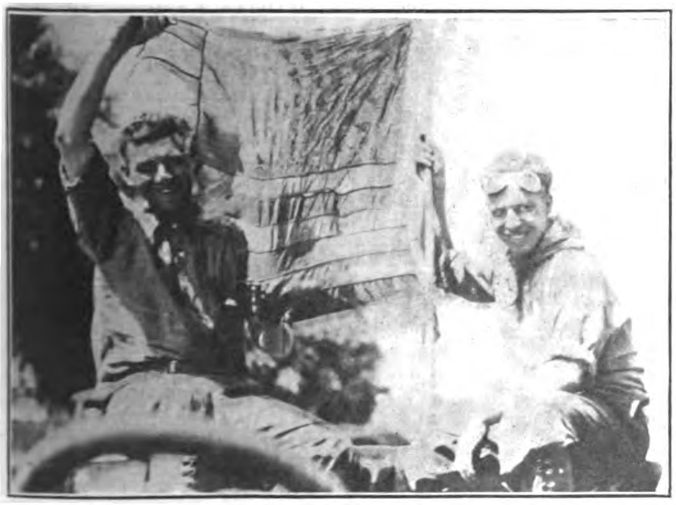
Michigan, Indiana and Illinois could well benefit by the example set by Iowa, Kansas and Nebraska, in the use of the drag. In fact, in some places it would seem that the use of this valuable piece of simple mechanism has been entirely ignored. As a result, in dry weather the roads are exceedingly sandy and rough, and in rainy weather, long stretches of mud puddles.

The greatest natural highways it was our pleasure to pass over lie in the State of Oklahoma. Oklahoma City is an excellent example of the benefits that are to be reaped thereby. Although only some twenty years old, it is a thriving metropolis, containing some 70,000 inhabitants, who own in all about a thousand automobiles. The farmers in the vicinity of Oklahoma City have realized the great value of the automobile and thousands are owned thereabout. With thousands of miles of beautiful, natural highways stretching away from her door, Oklahoma City proves the quick marketing place for the agriculturist with his crops, since with his automobile and the good roads he is able to land them at the market place in a short space of time. If he be a truck gardener he is able to have his produce in the hands of the consumer in much better condition than would be the case were he without the automobile, or level stretches of highway over which to drive it.

Built 380 Miles of Road in One Hour

Council Bluffs, Ia., July 4—The most remarkable feat in the history of good roadmaking was achieved in Iowa last week, when a road extending 380 miles, the entire width of the State was dragged in a single hour.

The dragging was the result of an agitation of more than six months. In March Governor Carroll called a good roads convention in Des Moines, and it was decided to have one piece of road, as nearly perfect as could be made from common dirt, extending from Davenport on the Mississippi to Council Bluffs.



What was left of Old Glory after the Regal completed the 5000-mile circle tour

Farmers along the way were induced to start the gigantic plan at exactly the same hour, and at 9 o'clock on the morning of the appointed day, hundreds of drags were on the job.

Farmers left their work, unhitched their horses from plows and cultivators, hitched them to drags, scrapers and road machines, and went to work.

"Pleasure" and "Commercial" Cars Defined

At the last meeting of the Association of Licensed Automobile Manufacturers, there was a general discussion of words that had crept into the automobile business which, in the opinion of many, were unfair to the trade as a whole. Such expression as "pleasure car," for a machine to carry passengers, was considered pretty poor nomenclature.

The term "commercial cars," as applied to freight-carrying automobiles, was considered a misuse of the term from the fact that all automobiles are commercial and practicable.

The general opinion seemed to be that in future, automobiles should be termed "passenger automobiles" and "freight automobiles," just as the railroads term their equipment "freight cars" and "passenger cars."

Crew of the "Plugger"—Lee Kuson, George Franklin, Norman Taylor and Roy Dean

Jersey Winners Each Rewarded

Each of the eleven cars that finished the recent 15-hour run of the New Jersey Automobile and Motor Club with a perfect score has been awarded a cup. The Motor Record cup goes to the Cadillac, winner in Class A. The Franklin, Haynes, and Buick pair in Class B were presented with cups by the Sunday *Call* of Newark, and the six winners in the other class were cared for by the club itself.

Dallas Dealers' Independence Day Meet

Dallas, Tex., July 4—Without breaking any records or suffering any mishaps, the Dallas Automobile Dealers' Club held its first strictly amateur race meet at the Fair Grounds track to-day. A crowd of fully 20,000 was attracted and the program of seven events proved spectacular and enjoyable. The summary:

Five miles; for cars of 10 to 20 horsepower—

	Car	Driver	Time
1.	Maxwell	Sluder	6:18
2.	Hudson		

Three miles; runabouts—

	Car	Driver	Time
1.	Maxwell, Jr.	Socksteder	7:00
2.	Bush		

Three miles; stripped roadsters—

	Car	Driver	Time
1.	Marion	Funk	5:47
2.	Locomobile	Girard	
3.	Kissel Kar		

Three miles; touring cars—

	Car	Driver	Time
1.	Kissel Kar	Wilson	4:15.20
2.	Moline		
3.	Regal		

Three miles; stock touring cars—

	Car	Driver	Time
1.	Thomas	Lindsay	4:15.20

Five miles; free-for-all—

	Car	Driver	Time
1.	Simplex	Bertrand	5:58.20
2.	Marion		
3.	Locomobile		
4.	Kissel Kar		

In the Realm of the Makers

Palmer & Singer have added a six-cylinder forty horsepower and a four-cylinder, fifty horsepower automobile to their line for 1 [illegible]

The Sup [illegible] Motor Vehicle Company has obtained [illegible] ermit to build a brick factory at 1686 E. [illegible] vood avenue, Buffalo, at a cost of $81,000.

The Moon Motor Car Company, of Indianapolis, has begun the erection of a handsome garage and salesroom on Capital avenue. It is two blocks from the heart of the business district.

John G. Utz, of the Abbott Motor Company, has a new engine, which he thinks will be suitable for aeroplane work. Experiments will be conducted in Detroit during the summer to try it out.

Harry L. Horning, secretary-treasurer of the Waukesha Motor Company, Waukesha, Wis., and Miss Elsie Muir, of Waukesha, were married recently and are now on a wedding trip through the East.

F. J. Manning, formerly connected with the Warner Speedometer Company and favorably known to the automobile trade, has also joined the Matheson Automobile Company as a salesman in the New York district.

The Ferromatic Tire Company, of Manitowoc, Wis., incorporated recently with a capital of $11,500, is now completing its tools, dies, patterns, etc., and plans to start manufacture of the new tire within a few weeks.

CHECK VALVE FOR LIMITING FLOW OF GASOLINE

Illustrating the check valve used on air-tight tanks made by Air-Tight Steel Tank Company, Pittsburg. (See Fig. 1.) When not in use the ball rests in the lower valve seat as shown in B. In this position it opens the ports G2, allowing the gasoline to flow in from the main reservoir as shown by the arrows D.

When pressure is applied in the chamber G2, the ball is forced up to A, closing the ports from G, permitting the fluid to pass on up and through the pipe and hose C.

In practice these valves are doing good work.

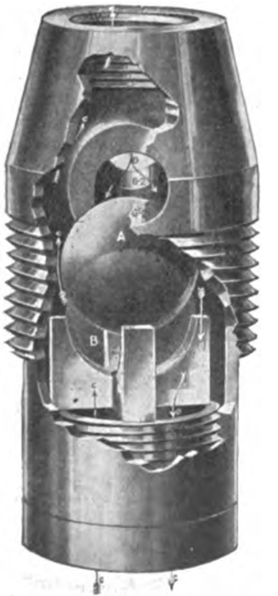


Fig. 1—Air-tight Steel Tank Check Valve

Frederick R. Simms, president of the Simms Magneto Company and founder of the Royal Automobile Club of Great Britain and Ireland has been selected as an honorary member of the Automobile Club of America by unanimous vote.

The Electric Welding Products Company, of Cleveland, has moved into its new factory addition, 94 by 100 feet, three stories high, and has installed new machinery, adding very largely to its capacity. The number of men employed approximates 350.

The Pennsylvania Rubber Company, which recently added $500,000 to its capitalization, making $2,000,000 in all, is now employing over 1,000 men at Jeanette, Pa. Herbert Du Puy, formerly president of the Crucible Steel Company, has assumed the presidency.

The Standard Auto Sales Company, of Youngstown, O., was incorporated with a capital of $10,000 to operate a garage and deal in automobile parts. The incorporators are Randall G. Anderson, A. Powers Smith, W. H. Anderson, J. H. Ewer and W. D. Euwer.

The Cincinnati Taxicab Company, of Cincinnati, O., was incorporated, with a capital of $20,000, to operate a taxicab service and do a general garage business. The incorporators are Frank E. Burnett, Allen L. Marshall, Chas. E. Everett, George B. Johnson and Alexander L. Sykes.

H. B. Harper, for the past two and a half years advertising manager and assistant commercial manager of the Ford Motor Company, as well as editor of the Ford *Times,* has assumed the position of export manager in New York just vacated by R. M. Lockwood.

T. W. Goodridge, prominently identified with the motor industry since its inception, has joined the forces of the Matheson Automobile Company. His first duties will be to establish agencies for the Matheson line of cars from Pittsburg to the coast.

The Troy Wind Shield Company, of Troy, Miami County, Ohio, was incorporated, with a capital of $10,000, to manufacture wind shields and other automobile accessories for automobile and garage purposes. The incorporators are H. F. Douglass, Henry L. Allen, F. A. Dillingham, C. G. Snook and B. Houser.

The Seagrave Manufacturing Company, of Columbus, will soon start to erect another large addition to its plant located in South Columbus. Some three months ago an addition was completed which doubled the capacity of the plant. The plans provide for an additional structure 150 by 200 feet, built entirely of steel and concrete. It is expected to have it completed and in operation by Fall of this year.

Robert M. Lockwood, located at 18 Broadway, New York, has shifted his allegiance from the Ford Motor Company to the Regal Motor Car Company, the position being the same one, that of export manager.

Fig. 2—How the Sonoscope operates

J. H. Dwight has resigned as secretary and treasurer of the Racine Steel Castings Company of Racine, Wis., to become secretary of the Kelly-Racine Rubber Company. S. H. Standish, formerly with the Finished Castings Company of Philadelphia, succeeds Mr. Dwight.

The Wentworth Motor Car Company, Cleveland agents of the Mora Company, gave a 1,000-mile sealed bonnet and starting crank test last week which proved eminently successful. The cars, which were driven by Mrs. Frank Adams and Miss Leota Mora, are both reported to have come through with flying colors.

SONOSCOPE FINDS THE KNOCK

Locating the knocks in a motor is not a difficult matter if they are neglected so that they graduate out of the "click" class, but the time to attack the problem is before the "click" becomes a knock. The American Sonoscope is an instrument which has been designed especially for this purpose. When it is placed in contact with the part whence a strange sound emanates, the little click will be accentuated until it assumes the proportion of the noise which comes from the blow of a trip hammer. It works on the principle of the Blake Transmitter working as a receiver. It occupies very little space and is free from all of the drawbacks of the character of instruments which persist in getting out of order even when horded under laboratory conditions. Fig. 2 shows the instrument being employed, and Fig. 3 is the instrument ready to respond to the demands of the autoist whose ear intercepts a strange noise emanating from the bowels of the motor. It is to be had from the Gaylor Automatic Stropper Company, Stamford, Conn.

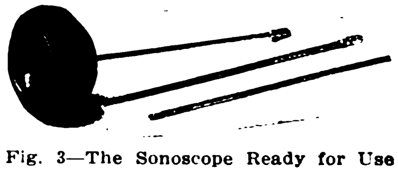

Fig. 3—The Sonoscope Ready for Use

E. L. Jones, formerly with the Anderson Carriage Company, has joined the sales forces of the Remy Electric Company, makers of the Remy Magneto.

Harry W. Doherty, sales manager of the Car Makers' Selling Company, distributors of DeTamble and Anhut pleasure cars and Dart delivery wagons, has gone to the Pacific Coast and will establish there a distributing company for California, Oregon, Washington, Idaho and Nevada, with branches in Los Angeles, San Francisco and Seattle.

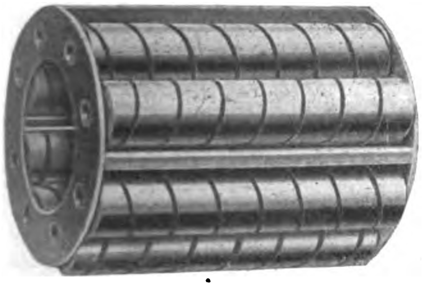

Fig. 4—One of the many types of Hyatt Roller Bearings, Made by the Hyatt Roller Bearing Company, Newark, N. J.

The Starr Automobile Company, of Minneapolis, Minn., has decided to build its proposed plant at Downing, Wis., according to reports from that city. Two blocks of land near the railroad line have been purchased and construction work will begin at once. The main building will be 90 by 200 feet in dimensions, with two 40-foot L-shaped wings. Seventy-five men will be employed at the beginning.

BULL DOG CHASES THE CARBON

The removal of carbon from the top of the piston is an important part of running an automobile engine because if the deposit is allowed to remain it becomes incandescent and preignition results. The engine knocks and thumps and the trouble spoils the running of a good car. A device intended to correct this condition by cleaning off the carbon deposits is the Bull Dog Carbon Remover manufactured by E. S. Michener of New Castle, Pa.

This device is guaranteed by the manufacturer to correct the condition. It is made of special tough, soft wire, so constructed that it will not catch under the valves. It is inserted through the spark plug hole, and, in conjunction with a little kerosene, quickly scours off the carbon if the engine is run without ignition in the cylinder being cleaned for a space of two or three minutes. The Bull Dog may be removed through the spark plug hole when its mission has been accomplished. It sells for 75 cents postpaid.

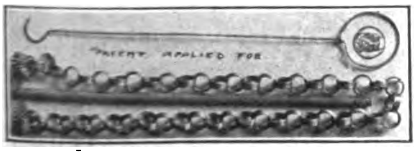

Fig. 5—The Bull Dog Carbon Remover

Agency and Garage News

Roman Jeria, of Para, Brazil, has taken the Brazilian territory for the Cole "30."

The Wood Garage and Auto Company has been incorporated at Niles, Mich., by L. E., F. J. and J. W. Wood.

D. H. Miller, of Water street, Binghamton, N. Y., has taken the agency for the Cole "30" for Central New York State.

The Cole "30" will make its début among New Orleans, La., dealers. The Gentilly Automobile Company has been appointed Louisiana agent.

W. C. Leland, general manager of the Cadillac Motor Car Company, who has been confined to his home for several weeks by illness, has recovered.

The Hennepin Auto Company, 422 First avenue S. E., Minneapolis, has taken the northwestern agency for the Hart-Kraft line of light delivery cars.

New agencies for 1911 Alco cars have been established by the American Locomotive Company with the Van Auto Company, at St. Louis, Mo., and with J. H. Fleming, at Scranton, Pa.

Marmon cars are now sold in Detroit by Collins & Company. Many excellent prospects are reported. Their location at 730 Woodward avenue, well up in Automobile Row, is an excellent one.

Two more branches have been added to the already long list of the Regal Motor Car Company, the latest additions being at Denver and Indianapolis. The first is in charge of E. S. Norton and the latter is presided over by C. C. Rundell.

The Hartford Suspension Company has opened a Chicago branch at 1458 Michigan Avenue under the management of William P. Pollitzer. A machine shop fully equipped with modern tools and in charge of skilled operators has been installed.

The Pierce Arrow Motor Car Company, of Buffalo, has opened a foreign service branch at 22 Avenue de la Grande Armee, Paris, France. Information regarding tours and motor routes and duplicate parts and accessories will be provided at this office which has been established for the exclusive convenience of Pierce Arrow patrons.

The Washington Bridge Auto Company, Inc., has opened its new three-story garage on One-hundred and eighty-second street near Amsterdam avenue, New York. The building is of commodious size, 45 by 119 feet and the entire structure with a well-equipped basement is utilized by the company. There are accommodations for 200 cars. A full line of supplies and accessories is handled. The company has not assumed the agency of any manufacturing concern so far, but arrangements for handling a moderate-priced touring car and a small runabout are being perfected.

The Crow Motor Company, of Elkhart, Ind., has decided to take part in the racing game. The company has entered two stock chassis for the races on the Indianapolis Speedway July 1-4. The company contemplates enlarging its plant in the near future.

Bill Nye, secretary of the Atlanta Speedway Association, has asked for tentative entries for a local race meeting to be held on the Speedway July 23. If enough interest is shown among local owners, a sanction will be applied for and races run on that day.

The Automobile Club of Dayton, Ohio, will hold an automobile carnival on Friday and Saturday, July 15 and 16. The committee on arrangements consists of E. L. Edwards, chairman; John Solliday, Thomas P. Gaddis, A. A. Wentz and Arthur J. Stevens.

SPARK PLUG REFINEMENT OF FITTING INTEREST

Refinements in ignition systems are being made with such rapidity that spark plug engineers are awakening to the necessity on their part of keeping pace with general progress. It is the same problem which obtained between gun-makers and the fabricators of armor-plate a few years ago; no sooner did the gun-maker produce a projectile and a gun to fire it which would pierce 12 inches of alloy steel armor in its hardened state than the fabricator of the armor plate studied the situation sufficiently to make it 16 inches thick and twice as hard as it was before. Now that magnetos are capable of delivering a spark of great energy under high potential conditions, it remains for the spark plug engineers to equal, if not exceed, the progress thus registered. Obviously, a spark plug which will not stand up to the magneto stress becomes the weakest link in the chain. The "Spit-Fire" type of plug is shown in Fig. 6. It is made by A. R. Mosler & Company, 163 W. 39th street, New York, to serve this end.

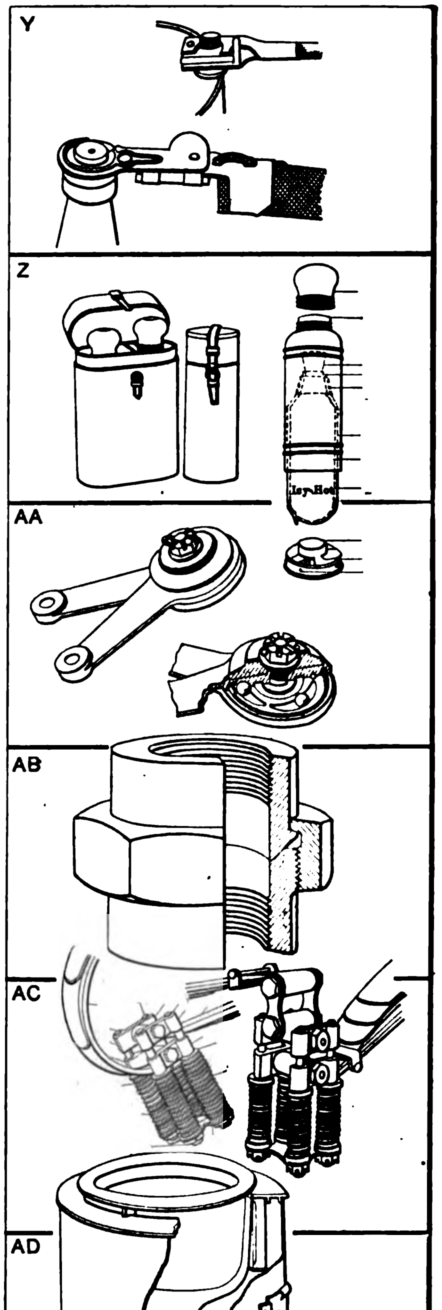
Fig. 6
Fir

Seen in the Show Window

SOMETIMES, when one's motor stops, the cause can be traced to a battery connector becoming loose or breaking—a trifle in itself, but an important item to the autoist. Much worry and sweating—possibly profanity—may be dispensed with by having in one's tool kit a supply of such indispensables. For the Becco connector (Y), manufactured by the Beck Company, of Rockville Center, N. Y., it is claimed that it cannot break or become loose, and that it accommodates itself to all positions of the battery caused by jarring or rough roads or otherwise. Another device marketed by the same company is the Becco terminal, which shows instantly when a cylinder ceases working whether the trouble is due to a bad spark plug or some electrical fault. The sparking gap indicates, when the switch is open, whether the electricity is properly going to the plug.

COMPARED with the early days of automobile touring, the motorist who contemplates a long trip across country nowadays may do so in comparative comfort, if not luxury. A cold drink on a hot day, or vice versa, is a blessing unalloyed, and no traveling kit should be minus some such accessory as the Icy-Hot Bottle (Z), manufactured by the company of the same name, in Cincinnati, O. These are furnished in quart and pint sizes, in black or russet leather, and lined with green velveteen. The outer casing is nickel-plated, and the glass vacuum bottle may be instantly removed from its metal casing for sterilizing, or if broken a new filler inserted. The screw top is in the form of a drinking cup.

HOWEVER excellent may be the spring equipment of a car, the use of some form of shock absorber to take up the constant jar and vibration which are inseparable from a trip over rough roads, is absolutely necessary if the car, its engine and the tires are to be assured of a reasonable length of life. For the device here illustrated, the Ball-Bearing Shock Absorber (AA), now being marketed by the company of the same name at 25 Broad street, New York, the claim is made that they positively neutralize all jounces and jolts without tying, binding or detracting from the best action of springs, reducing the wear on the parts and minimizing to almost the vanishing point the possibility of breakage. They are made of the finest steel drop forgings, with highly tempered double incline ball runways and best steel balls. A metal dust guard protects all wearing parts from dust and grit.



Y—The Becco Connector and the Becco Terminal
Z—The Icy-Hot Bottle and Holder for Touring
AA—The Ball-Bearing Shock Absorber—a Necessity for Rough Roads
AB—The Air and Gasoline-Tight Octagon Kewanee Union
AC—The Velvet Auxiliary Spring—Another Form of Shock Absorber
AD—The Buek Metal Melter—Handy to Carry from Shop to Job

EVERY repairman, garage-keeper and owner of an automobile realizes the necessity of tight tubing. Where a union is necessary in a tube line, either for water or gasoline, a leak is possible unless a positively tight joint can be secured by means of a reliable connection. Some of the claims made for the Octagon Kewanee Union (AB), manufactured by the National Tube Company, Hudson Terminal Building, New York, are the absolute tightness of the brass-to-iron thread connection at the ring; the brass-to-iron joint ball seat; and the possibility of easily disconnecting the joint if necessary. These unions are subjected to a 100-pound air pressure test, under water, to insure absolute tightness.

LIKE riding on velvet—an apt simile when used in connection with the spring-within-a-spring device now being sold by the John W. Blackledge Mfg. Co., 1400-1402 Michigan avenue, Chicago. The Velvet Auxiliary Spring (AC), it is claimed, performs all the functions of the spring link, eliminating all side sway which might have a tendency to bring undue strains on the other parts of a car. The eight coils which support the weight are surprisingly light, and are consequently very sensitive, interrupting and distributing the road shocks so effectually that the sensation is akin to riding on velvet.

LATTER-DAY shop needfuls have a recent worthy addition in the Buek Metal Melter (AD), made by the Frictionless Metal Company, of Chattanooga, Tenn. This handy repair device has the prime merit of being of such size and weight that it may be easily carried from shop to job, saving time and doing away with the necessity of taking job to shop. Gas is the fuel used in this melter, but an advantage claimed for the Buek over other forms of gas-using melters is a 30 per cent. saving, accomplished by means of a warm-draft burner. In operation it is extremely simple, and there is no additional expense incurred for fan blast or compressed air.

ELECTRIC lighting is now being practiced in connection with automobiles on a large scale, and the "Electrobola" is one of the latest bidders for honors in this field. The lamp is in the form of a parabola, 10 1-2 inches in diameter by 7 inches deep and weighs 7 1-2 pounds. It throws a beam of 2500 candlepower, and is aimed at the road 700 feet ahead of the automobile. It is made by the Avery Portable Lighting Company, Milwaukee, Wis.

XXIII NEW YORK—THURSDAY, JULY 14, 1910—CHICAGO No. 2

THE AUTOMOBILE

Excellent Sport at Plainfield Club's Second Annual Hill Climb

BUICK, CHARLES JONES, DRIVER, WINNER 161-230 CLASS

OVER a course that is pronounced by experts to be far and away the most difficult in the East, the Plainfield Automobile Club, of Plainfield, N. J., conducted its second annual hill climbing contest, Saturday afternoon. Some astonishingly good time was made in the ten events; not a mishap of consequence marred the pleasure of the day and good management and good weather combined to make the sport enjoyable to a crowd of well over 10,000 persons.

The hill is called Johnson's Drive, but it never could have figured much as a pleasure speedway, for it is steeper than the Dead Horse hill at Worcester, and more tortuous than Giant's Despair at Wilkes-Barre. Just short of 4,000 feet in length, there is not a stretch of 100 yards without its wrenching turn or heart-breaking grade. The total rise is only 300 feet, but it certainly seems much greater. The starting point is on level ground and the course is practically flat for 75 yards, then swinging around at right angles it mounts a stiff grade to a letter S curve that is so sudden that it makes the ordinary hairpin turn look like a straight line. Then comes almost a circle of heavy grade, followed by another rectangular turn, and the finishing stretch is a little less than 100 yards of comparatively straight going.

The turns of the letter S curve were banked, which explains the fast time made on the general average. De Palma in the free-for-all did not keep his throttle open for longer than 10 seconds at any one time in making the record-breaking ascent. His huge motor, roaring like a lion, was opened and closed a dozen times during his trial and finished with a rattle of explosions that sounded like a machine gun in action.

The day was perfect and long before the scheduled hour for starting crowds assembled along the course. Practically every person in the big crowd had a program and, remarkable to relate, the running of the events was precisely in accordance with the terms of the program.

Five Hupmobiles and a Schact competed in the first event, all finishing the course in creditable shape, with the honors going to the Hupmobile owned, entered and driven by A. C. Dan, in 2:04. On account of the size of the Hup, it was able to negotiate the sharp turns in commendable style. The Schact, which appeared during the morning for final practice stripped to the running gear, was required to replace the ordinary body on the car. The sudden change in rig probably did the car no good in the running of the event.

Event 2 was taken rather easily by a Mitchell, but the running of the race was marked by a bit of hard luck for the Oakland entrant. This car came whooping up the hill and was finishing about 10 seconds better than the time of the winner, when the clutch began to slip and the motive power died out, [illegible] thing Driver [illegible] could do,

1—Dean Rankin's Chalmers "30" which won the 301-450 race

2—Houpt-Rockwell, victor in the 451-600 event

3—The big Fiat, which De Palma drove to the course record

4—The Krit, which captured the place in the 160-230 race

within thirty feet of the winning line. Buick 22 also participated in the tough luck of the hill-climbing game in this event. The car suffered two blow-outs on the first turn and could not finish.

As the Oakland certainly had a margin of 10 seconds when the clutch went wrong and as the Buick later in the afternoon won in its piston displacement class in 21 seconds better than the winner of this event, some of the elements of racing luck were particularly emphasized.

Event 3 was captured by the Correja in easy fashion. During final practice this car suffered a broken front axle and the substitute piece was only installed a few minutes before the car was called to go upon the line. In its piston displacement class the new front axle of the Correja snapped when the car was making the big circle, and Driver Joe Taylor had all he could do to keep the car from diving over the precipice. No one was hurt, however.

Event 4 was won by the Buick driven by veteran Phil Hines, who remarked after the race that in his ten years of driving experience he had never encountered anything like the Johnson's Drive.

The classes for the more costly touring cars did not fill and the next event was No. 8, the free-for-all. E. W. C. Arnold's Fiat, driven by De Palma, broke the record for the hill by 8 seconds, finishing in 1:20. He had to make the big special car go at a record clip because two stock cars that finished behind him came so close that they also broke the former mark. These were the Chalmers, driven by Rankin, which made 1:22 1-5, and the Houpt-Rockwell, Stanley Martin, which made 1:22 3-5.

Event 9 produced a pretty fight. The Maxwell was the only entry up to a few minutes before post time, when two K-R-I-Ts made post entry, and just a few minutes before the race the little Buick that suffered the blow-outs in its price classification race was thrown in. The result was that the Buick won by nearly 21 seconds, while the K-R-I-Ts fought it out for second place. Through a misconception of the rules for stock chassis classes, which do not require the same load to be carried as those applying to the touring car divisions, a protest was about to be filed against the winner on behalf of the K-R-I-Ts, which carried the full complement of passengers; but the matter was eventually explained to the satisfaction of all.

Event 10 was taken by the S. P. O. after the Gorreja broke its axle, and event 11 was won in astonishing style by the Chalmers entrant. This car had finished second in the free-for-all and was generally looked upon as a sure winner, but in making the first turn Rankin suffered a blow-out of the right rear shoe, despite which, however, he continued and managed to get across the line in 1:27 2-5, leaving him a winning margin of over 2 seconds.

Event 12 for cars with piston displacement of from 451 to 600 cubic inches found three contestants, a Houpt-Rockwell and two Stearns cars. The Houpt-Rockwell proved an easy winner in the same time it made in the free-for-all. The final number, an amateur event, brought out only the two Stearns cars that competed in the preceding number. The machine owned, entered and driven by C. W. Winslow got home in 1:28 3-5.

Cups were awarded the winners in each of the classes and cash purses were given the first and second in the free-for-all.

The officials who handled the affair were as follows: Referee, J. H. Wood; starter, Arthur Smith; timers, Dr. F. C. Ard, A. L. C. Marsh, G. J. Tobin, C. E. Verian, E. A. Lowe and E. Rushmore.

Contest Committee, Hugh A. Todd, Alexander Milne, Allen B. Laing, F. L. C. Martin, C. B. Brokaw, A. C. Thompson, Kent Bender, Gus Barfuss and Hiram A. Woodruff; Technical Committee, A. F. Camaclo, R. D. Williams, F. O. Ball and H. A. Todd.

The officers of the Plainfield Automobile Club are: H. W. Marshall, president; Hugh A. Todd, vice-president; W. R. Townsend, secretary, and F. O. Bell, treasurer. Following the race program the club entertained the entrants at dinner in the club rooms at the Brass Kettle Inn. The summaries:

Sweepstakes Announced for Parkway

W. K. Vanderbilt, Jr., president of the Long Island Motor Parkway makes announcement that on Saturday, July 30, the "Motor Parkway Inaugural Sweepstakes" will be held on Long Island. There will be a sweepstakes amateur event at 10 miles, a free-for-all event and a Class C event for cars ranging from 301 to 600 cubic inches piston displacement, without weight limitation.

Valuable cups will be given in the amateur and the Class C events, with first and second cash prizes of $100 and $50 in the free-for-all event.

The conditions for these two are practically identical with those that will prevail in the Vanderbilt Cup race to be held on the Parkway on October 1, and the Grand Prize race on October 15, this fall.

It is expected that the amateur event will bring a large field of entries from the Amateur Contest Association.

The timing will be done by the Warner electrical timing device. The start will be near Great Neck Lodge and the finish at the grand stand on Hempstead Plains. The greater portion of the course will be on the newly completed section of the Parkway which has a surface of tar-treated sand and gravel, laid on cement. The curves are all scientifically worked for sustained high speed—sliding, slipping and skidding are eliminated and there is absolutely no dust. Phenomenal time, undoubtedly, will be made.

Drivers of motor cars can approach the stand from Great Neck, Roslyn, Jericho and Meadow Brook lodges up to 11:30 o'clock a. m., when the Parkway will be temporarily closed for the start, which will be at 12 o'clock noon.

All events will be run in heats of two cars, with finals and semi-finals affording an afternoon of high-class sport. Entry blanks may be obtained from A. R. Pardington, second vice-president, at Mineola, L. I. Entries will be received up to the last mail on July 28.

New Automobile Law Under Hamper of Political Expediency

Chauffeurs' Qualities to Be Shucked in Seven Seconds

State of New York Appended to a Touring Club Enterprise

THESE are lively days for the chauffeur. He is being examined as to his qualifications touching on and appertaining to the propulsion of the automobile and his knowledge thereof. The great and sovereign State of New York is propounding the questions, through the instrumentality of Frederick H. Elliott, erstwhile secretary of the A. A. A., and more recently secretary of the Touring Club of America. In fact, Mr. Elliott is still secretary of the latter organization, and despite his new job as chief examiner of chauffeurs he is to be found in the offices of the club at Seventy-sixth street and Broadway.

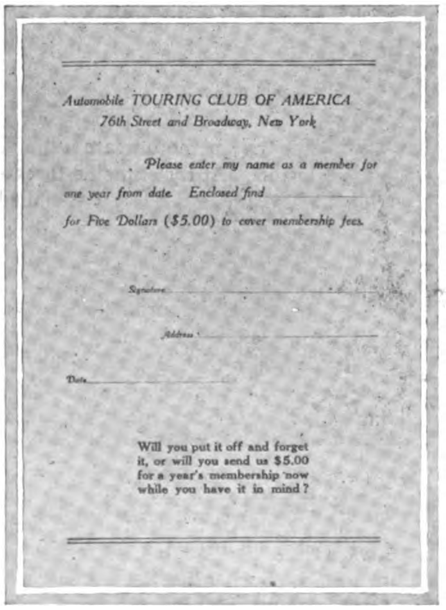
But, as was said, these are the days when the 35,000 chauffeurs of New York City are as industrious as a boy with his first Waterbury. If they intend to obey the law, they must pass Mr. Elliott's examination, whereupon a certificate of character and ability will issue to them from the fountain head of the State. The Callan law provides for registration of chauffeurs, but does not outline the procedure. It delegates that power to the Secretary of State, and that official, in his discretion, passed the "buck" to Frederick H. Elliott, as chief examiner in this district.

Mr. Elliott was instructed to frame a series of questions that would test the knowledge of the applicants for certificates, so that if they were answered satisfactorily, the great American public might employ the holder of a certificate with full assurance that the aforesaid holder would not make it a practice to do miles in :47 before dawn on Riverside Drive; that they have distinct knowledge of the difference between the transmission and the magneto and they have only such criminal records as they have confessed to in their applications.

All these things are important and greatly to be desired, and in the wisdom of the Callan law the delegation of powers under it to the Secretary of State and the subsequent passing of the "buck" to Mr. Elliott, the officials certainly have made a showing of activity.

The procedure is simplicity itself. All the applicant has to do is to go to the offices of the Touring Club of America and ask for blank application papers. Any of the half-dozen obliging clerks of the Touring Club will be pleased to supply the blanks, or if the applicant wishes to get them in other ways, such a thing may be done. Mr. Elliott himself sometimes stands behind the counter, upon which is piled literature and prospectuses of the club and insistent little blank applications for membership, at $5 the year.

Of course, the applicants for State licenses as chauffeurs do not have anything to do with these applications for membership in the club, but many of them wonder whether such membership might not have its advantages.



Automobile TOURING CLUB OF AMERICA
76th Street and Broadway, New York

Please enter my name as a member for one year from date. Enclosed find ______________ for Five Dollars ($5.00) to cover membership fees.

Signature ______________________

Address ______________________

Date ______________________

Will you put it off and forget it, or will you send us $5.00 for a year's membership now while you have it in mind?

At any rate, they have the chance to look at the applications for membership while they are waiting for the obliging clerks to furnish them with applications for license. In fact, they may examine the maps and pretty signs of the Touring Club of America, while leisurely polishing up their spelling or syntax or sharpening their descriptive faculties for the ordeal of examination.

The application blank, when it has been sifted out from among the other literature and application blanks for membership in the club, is found to be a beautiful pink affair containing 19 queries of an intimate and personal nature.

Counting to-day, there are exactly 16 working days during which applicants may be examined before the law goes into effect. Woe betide any luckless chauffeur who fails to have an "engrossed" certificate on the morning of August 1, 1910! Preparations are being made to cause the careless ones and the unfortunates who fail to take the examination to rue the day they overlooked their chance.

A room has been secured for the work of examining the applicants. It contains desks for chauffeurs, and Mr. Elliott says it will be operated hard as soon as things get to going smoothly.

When seen at the rooms of the Touring Club of America Tuesday, Mr. Elliott seemed quite certain that all would be accomplished according to the seven-second schedule. But in discussing the matter, one little jarring note pervaded the harmony of the conversation. Said Mr. Elliott:

"Nobody knows exactly how many applicants we will have to examine, but I believe we shall be able to get through all right. I am not stuck on the job, but everybody seemed to think I ought to take it and keep it, and so I am working at it. But it is tough for the State officials to set a man to do a certain thing in a certain time and then hamper him with dull tools. Of course, some of the men who have been selected for the board of examiners may be all right, they do not shape up with my ideas as to what board members should be. In selecting a board under political auspices, the best of material is not always available, and I suppose we shall have to do the best we can with the material furnished. I can say that if I was selecting the board it would have had a far different complexion."

The names and addresses of the board that Mr. Elliott referred to are as follows:

George Abrams, 66 Orchard street; A. Asen, 121 Broome street; James Bennett, 286 Degraw street, Brooklyn; Frederick Beyer, 548 West Fifty-first street; John E. Carney, 325 President street; Nicholas D. Collins, 377 Atlantic street; Robert H. Cowden, Jr., 33 Ross street; David C. Decker, Port Richmond; Samuel Ginsburg, 222 Rivington street; Abraham Gold, 713 Seventh avenue; Samuel Hoffman, Confidential Clerk, 272 East Houston street; George M. Janvrin, Examiner of Publicity, 302 Westminster road; Fred Kuser, 441 East Fifty-seventh street; Walter R. Lee, 554 Ninth street; Jesse F. Madden, 241 Powers street, Brooklyn; James R. Murray, 116 West Seventy-first street; George H. Nason, 57 Greenpoint avenue, Brooklyn; Mark Natkiel, 612 Sixth street; Millard C. Perkins, 319 West Fifty-fourth street; A. E. Preyer, 170 West 136th street; Charles Reich, 233 Tenth avenue; M. J. Rogan, 330 West Forty-seventh street; John A. Saam, 478 West 146th street; Harry Safir, 341 Sixth street; Robert Spitzer, 236 Linden avenue, Brooklyn; Emil Stecher, 745 Sixth street; Seymour Taft, 259 Mott avenue, Long Island City; William K. Tattersall, 81 Enfield street, Woodhaven, L. I.

The examination, in order to accomplish the intention of the law, must be severe and searching. When it is all over and the official O. K. of the State is placed upon the papers, it is supposed to prove the competence, honesty and industry of the chauffeurs. Only one thing stands in the way, and that is the matter of time.

It has been figured that working union hours every day from now until the law goes into effect, the examining board can devote a little less than seven seconds to each applicant for examination. If the board works four full shifts each day, including Saturdays, which is an unbelievably liberal estimate, they will be working 230,400 seconds, and as there are somewhere around 35,000 chauffeurs who must be examined by August 1 in order to avoid various dire penalties, an example in long division will show that seven seconds per applicant is a reasonable estimate of the amount of time that can be devoted to each.

As an expert writer is able to sign his name in about that time, the problem that confronts the chauffeur is by no means as simple as it might appear.

A conservative estimate of the number of chauffeurs engaged in New York City and vicinity, known as District No. 1, is put at something like 35,000. The sovereign State of New York, in its wisdom, places 35,000 citizens and their chances of making a living at the mercy of the Chief Examiner, who admits that he is engaged in another business, and whose name appears as Secretary of the Touring Club of America; he is bound by his oath of office to examine every chauffeur as to character and competence, and if he expends all his time in the interest of the office which has been handed to him by the Secretary of State he will have apparently less than 7 seconds of time in which to keep from being a perjurer. But he is engaged in other business, and if he spends any time at all in the conduct of his private affairs during the working hours as figured out herein, he will make more or less heavy inroads upon the few seconds of time which already stand between him and perjury.

Granting that the Chief Examiner is a diligent servant, the fact remains that the chauffeurs to be examined, if they while away any of the fleeting seconds to which they can possibly lay claim, reading the literature of the Touring Club of America, will further reduce Mr. Elliott's ability to place at the disposal of the owners of automobiles 35,000 capable chauffeurs in 230,400 seconds, and if, as the Secretary of State proclaims, the citizens are to be given the administrative advantages of a particularly wise law, the wonder is what became of the wisdom that made it possible for the chauffeur to spend any part of his precious seven seconds amid the distractions afforded by the literature of the Touring Club of America, its officers, or any other literature or persons not directly connected with the administration of the law.

At the American Automobile Association's office, when the peculiar way in which the new law is to be enforced was discussed, it was stated that the matter had been called to the attention of the Association of Automobile Clubs of the Empire State, and the opinion was expressed in forcible language that the mixing of the new automobile law with the private affairs of individuals was a gross injustice to the autoists, who will be discommoded to whatever extent the law becomes abortive.

It is confidently anticipated that the projectors of this law will feel the pressure of the indignation which is being aroused, not only in the ranks of autoists, but in the community at large, over the totally inadequate way in which the matter is being handled, and it looks as if political expediency, rather than the promise of efficient work, is the normal expectation.

Wisdom, tempered with experience, demands that chauffeurs be regulated, but by no power of the imagination can it be shown that they should be exploited. The law distinctly states that a man is to be deemed innocent until he is proven guilty, and under the law a chauffeur is entitled to the distinction of being considered a good citizen until it can be shown, by legal means, that he is not. Political expediency may have the telescopic eye which will permit it to single out a goat from the sheep in seven seconds of time, but the average citizen will scarcely be convinced of the efficacy of the plan. Thirty-five thousand chauffeurs are entitled to the exclusive service of a Chief Examiner and a corps of inspectors who are free to devote their entire time to the examining effort, and it is not believed that the State of New York can afford to put a straw in the way of a man who is entitled to the right to earn an honest living, even if he is a chauffeur.

Leading British Aviator Meets Death

BOURNEMOUTH, ENGLAND, July 12—Falling about 100 feet when the tail piece of his Wright bi-plane snapped off, the Hon. Charles Stuart Rolls, third son of Lord Llangattock, and one of the leading automobilists, aviators and balloonists of the United Kingdom, was dashed to death this morning in the presence of a large crowd composed in part of personal friends and acquaintances of the aviator.

Mr. Rolls was engaged in an accuracy contest at the time of the accident and was about to make a descent, when his aeroplane crumpled directly in front of the grandstand. He was dead before assistance could reach him. In addition to the fame he recently gained on account of of his non-stop flight across the English Channel to Calais and return, Mr. Rolls had been identified with advanced ideas in motoring and was connected with the Rolls-Royce Company, which manufactures the car of that name and which bears an excellent reputation for mechanical perfection.

He was only 33 years old and had been educated for the diplomatic service, but owing to the mechanical trend of his mind, a career in that direction was abandoned. As a balloonist he made over 150 ascents and crossed the Channel several times before the day of the aeroplane.

In the field of aviation he stood in the front rank of the world. At the time of his death he was contemplating a trip to the United States to take part in various aviation meets and transcontinental competitions scheduled for the coming fall.

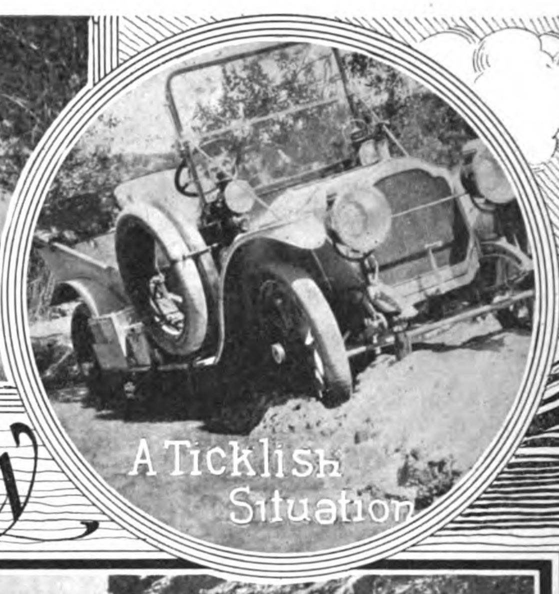
Boston Parkways Closed to Automobiles

BOSTON, July 11—Boston motorists were very much disturbed to-day when they read in the papers that the Boston Park Commission had made a ruling that several roads heretofore opened to motor cars had been ordered closed at the request of Mayor Fitzgerald. If the ruling is upheld by the State Highway Commission, it means that motorists will have to go out of their way in many instances coming into Boston and going out, for some of the parkways lead directly to other near-by cities and towns.

This is the outcome of the agitation last spring by Mayor Fitzgerald to get 25 per cent. of the fees from motor cars for the maintenance of the park roads in Boston. At that time he threatened to order all parkways closed if his request was not complied with by the Legislature. This was refused and he sent out requests to both the Boston and Metropolitan Park Commissions asking that they close all parkways to the motor cars.

The Metropolitan Park Commission replied promptly that it would not do so. The Boston Commission did nothing until today, and its action is based upon the fact that already the State has collected more than $300,000 from motorists, with more to come, which, with the regular State fund, makes more than will be needed for the State highways. The Legislature will have to act before any sum can be set aside, however. The matter is now placed squarely up to the State Highway Commission, for the rules cannot be enforced until the Commission approves of them. A hearing has therefore been set for July 27. By [illegible] time th motorists will be organized strongly against th

Good Roads Needed



A Ticklish Situation

Through Death Valley

TOWARD the Southern end of the Mojave desert, where the shadows at dawn and twilight lie purple and rose-color in the swales and arroyos that depress the yellow-gray sand, there is a territory that gives little promise for a colorless automobile trip, and the negative promise is more than fulfilled when the venturesome automobilist essays to solve its eternal problem.

J. M. Murdoch, of Johnstown, Pa., and Pasadena, Cal., who has driven a Packard car from ocean to ocean for the fun of the thing, is one of the motorists who has had the nerve to traverse the Mojave wastes clear to the portals of Death Valley. So far this year he has made two intensely interesting trips. The first was early this Spring, when he and a party of adventurous spirits tested the possibilities of a run through Daggett and around Coyote Lake to the gateway that leads into Death Valley. This trip was accompanied by a world of incident and enjoyment, and some of the roads traversed were among the most picturesque in the world.

The second tour was through the desert, skirting Owens Lake and circling through the wild waste at the base of Mount Whitney, the stateliest spire of the lower Sierras, whose head is crested eternally with a crown of snow and ice.

Over passes that seem fit only for sure-footed burros; through narrow cañons whose walls rise so high that they shut out the sunlight at noon; passing by vast stretches of waterless desert where the land is so rich that anything that grows anywhere on earth can be made to flourish mightily with the aid of water, the party explored a dozen trails that have never before been part of the itinerary of an automobile party.

They passed over great tracts of heavily mineralized country where in times past pioneer prospectors staked and lost their labor, property and lives, and they also whirled by the section in which the Spanish friars of the dead centuries labored to unearth the surface treasure of chrome silver and the marvelously rich pockets of metallic gold that served to check settlement in California until the tidal wave of 1849 swept their conservatism away.

The first part of each of the tours of Mr. Murdoch was through a delightful road setting, but before he had reached his

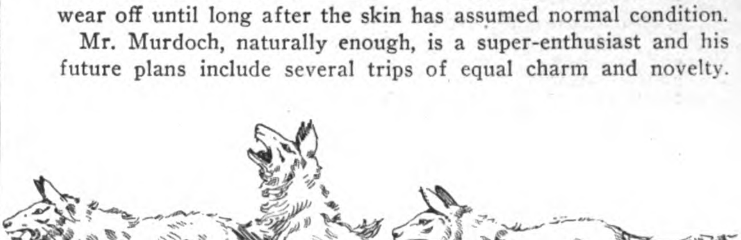
40-Horse and 4-Horse

destination in each case he had figured in the rôle of pathfinder for humanity. There were a dozen spots over which his automobile was pushed where the foot of white man, the hoof of domestic animal or the wheel of the automobile had never passed before. Among the more spectacular scenes which figure in these tours are the passage of Cajon Pass, high in the Sierras; the San Francisquite cañon, a rift in the dry hills; the unspeakably rocky trails of Red Rock cañon; the silence and mystery of the Soledad and the depressing stillness of Death Valley itself. The valley is from five to ten miles wide, the higher ground being a formation of immense sand drifts. During heavy wind storms these drifts are shifted and blown in every direction. The Murdoch party was frequently compelled to put up top and curtains to keep off the sand the wind blew so fiercely about them. The Newhall grades, that once afforded a certain kind of freight thoroughfare and which in their time have carried untold millions of treasure packed on mule-back or dragged along by great strings of sturdy little horses, were used by Mr. Murdoch's party. The Newhall trail is considered to be about the stiffest pull in the United States—at least the steepest long grade in the country that is used for hauling. In places the grade is fully 27 per cent., thus affording a rigorous hill-climbing test. In the course of a short time the Newhall trail will be abandoned permanently, as a road tunnel is in course of construction that will allow hauling at a much more gentle grade than the old landmark trail over which Mr. Murdoch and his party passed.

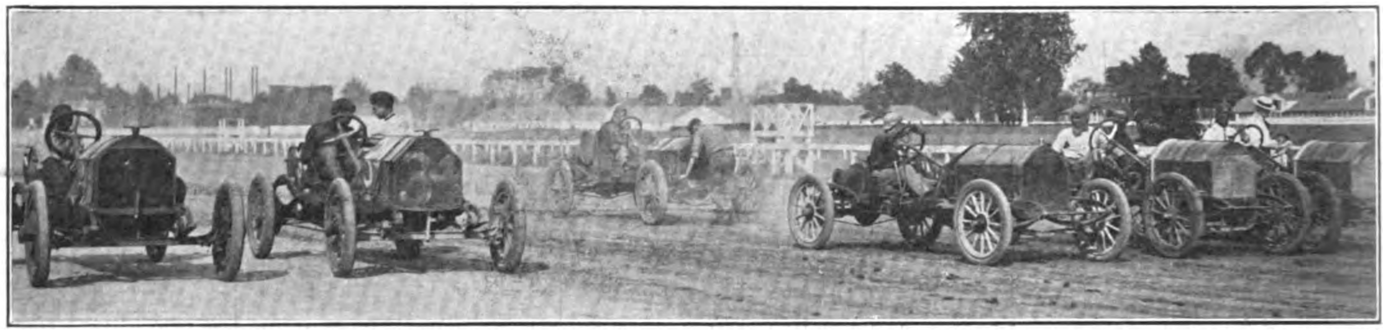
The party took a spin on the floor of Death Valley, which is as level as the floor of a ballroom. The sand is glistening white and in the full glare of the California sunshine the reflection of the light is dazzling in its intensity and glory.

When tourists return from such trips as those enjoyed by this party, faces are tanned to a temporary hue of russet leather or broiled to a shade that matches that of a Nova Scotia lobster, but the time spent in the free, wild atmosphere of the desert and mountains is said to act as a tonic, the effect of which does not wear off until long after the skin has assumed normal condition.

Mr. Murdoch, naturally enough, is a super-enthusiast and his future plans include several trips of equal charm and novelty.



Marmon Team Starred at Churchill Downs



Line-up for the five-mile free-for-all handicap at Churchill Downs, won by Hughes' Parry

LOUISVILLE, KY., July 11.—The motoring fans of this city witnessed a program of automobile races last Friday at Churchill Downs that never before has been surpassed in Kentucky. Nine well-contested events were run, and, best of all, there was but one accident, and that not serious. Harry Endicott, the E-M-F driver, was the sufferer in this, but was not dangerously injured. In the second race, before the first mile had been negotiated, the car was hood to hood with the Cole entries when a heavy cloud of dust made it impossible for Endicott to see. Speeding along at a lightning rate the machine left the track and dashed through the fence, crashing into the west wall of a stable.

The Marmon team starred on the opening day of the speed carnival and captured the biggest events of the day. The dirt track was slow because of recent rains and no records were smashed. Ray Harroun made an attempt to lower the world's record for a mile on a dirt track, but was unsuccessful. His time was 59 seconds. The most spectacular event of the afternoon was the twenty-five mile race. In Class B Ray Harroun was the first to flash past the judges' stand in 28:33, while Bill Endicott in a Cole carried off honors in Class A. His time was 31:42. Behind Endicott came No. 11, also a Cole, driven by the skilled hands of Edmunds.

Emmons (Herreshoff) won the trophy in the fifth race, which was a well balanced handicap event of five miles. Every foot of the way was bitterly fought in the free-for-all handicap event. There were seven starters. Hughes (Parry) carried off the first prize, when he negotiated the five miles in 6:05.

A remarkable feature of the day's races was that throughout the nine events there was no tire trouble of any sort. None of the local contestants entered in the events could stand the pace set by the professionals and they carried off no honors.

Eugene Straus, president of the Louisville Automobile Club, was the official referee and representative of the Contest Board of the American Automobile Association. The starter was H. C. George; judges, Lee L. Miles, Walter Kohn, L. H. Wymond and Hubert Levy. All of the officials were selected from the membership of the Kentucky Automobile Association, the Louisville Automobile Club and the Louisville Automobile Dealers' Association. The summaries:

Pos. Car	Driver	Time
Five miles, under 160 class—		
1—Herreshoff	E. P. McCormick	6:45
2—Herreshoff	Walter Emmons	
3—Herreshoff	William Smith

2—Marmon	Joe Dawson	
3—Stoddard-Dayton	J. K. Gilchrist	

LOUISVILLE, KY., July 9—Heavy rain put a stop to the Grand Circuit auto races at Churchill Downs on the final day of the meet. Despite the weather conditions during the early part of the afternoon more than 1,000 motoring fans hied themselves to the famous course and for two hours sat in the grandstand waiting for the races to start. Their appetites had been whetted by the splendid card offered by Homer George and W. H. Wellman, the promoters, on the opening day, and they were anxious to witness more of the dare-devil driving of the speed kings on a one-mile dirt track.

At 3:30 o'clock the rain fell in torrents and owing to the dangerous condition of the track the management called the races off.

Marmonites Repeat at the Cincinnati Meet

CINCINNATI, O., Juy 10—The circuit-chasers came here to-day ftom Louisville for the track meet at the local course. As at Churchill Downs, the Marmon team swept the boards, although the Herreshoff and Cole also captured the class events. Summaries:

Pos. Car	Driver	Time

Gilchrist in Stoddard and Stevens in Matheson also started but quit on account of dust.

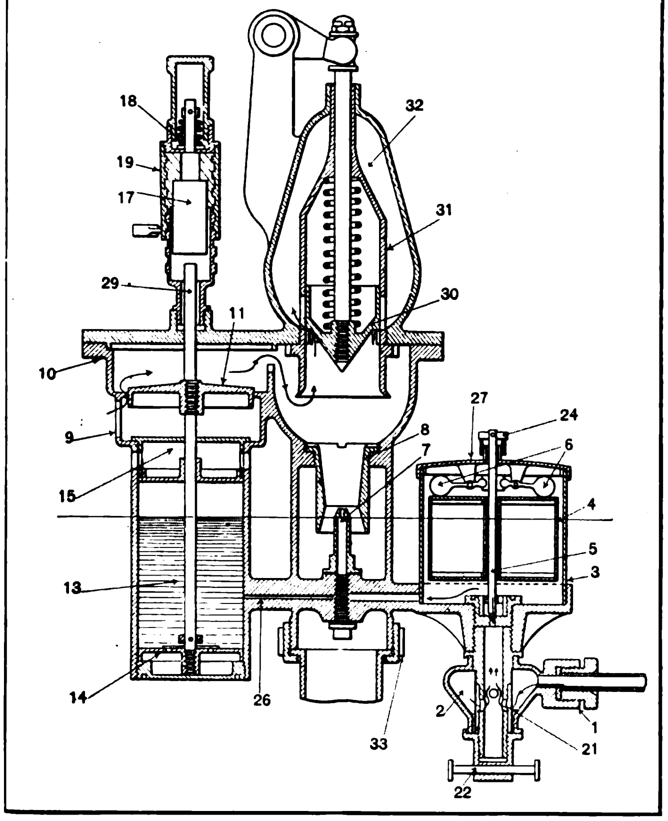
New Carbureter on 18-Horsepower Renault Car

As reported from abroad, the new Renault carbureter as used on the 18-horsepower car, has several new features: float is used as usual; supplementary air intake has some leading features; troubles of spring control systems are eliminated; dead weight methods obtain; fluid dashpot effect is taken advantage of.

FROM the "Foreign Correspondent" comes the report of a new carbureter differing in several important features from the present model, which has just been patented by the Renault Company and adopted on the firm's 18-horsepower, six-cylinder car; it will probably later be applied to all the firm's four-cylinder models. As will be seen from the sketch, the gasoline is brought to a cone-shaped chamber 2, from which it mounts, by reason of the difference of level, into the float chamber 3, the nozzle 7 and the cylinder 13. The choke tube 8 has its diameter calculated to allow the passage of the right quantity of air for the correct running of the motor at low speed. The primary air is heated by a by-pass from the exhaust, but the supply of warm air can be shut off, whenever required, by turning the collar 33.

Supplementary air is admitted through the valve 11, forming the base of the supplementary air chamber communicating freely with the mixing chamber above the choke tube. At the lower extremity of the stem of the air valve is a piston capable of an up and down movement in the cylindrical chamber containing gasoline and communicating with the float chamber by the passage 26. As the piston meets with a certain resistance by reason of having to move within a fluid, the rapid vibrations common to spring-controlled valves are abolished. The valve opens very gradually, and is equally slow in falling back to its seat. The gasoline within this cylinder having no other object than to steady the movement of the auxiliary air valve, it is prevented from overflowing or passing in with the air by the presence of the intermediary chamber 15.

About 1-8 inch above the upper extremity of the valve stem 29 is a counter weight 17. The initial opening of the valve is, therefore, made without any difficulty, the only resistance to overcome being that of the piston within the gasoline tube. As soon as the stem comes in contact with the balance weight, however, further opening can only be made by overcoming the weight of the balance and the spring 18 to which it is attached. The weight of the balance and the tension of the spring are calculated to give a correct lift and in consequence a correct amount of air for all engine speeds. The absence of violent movement of the air valve at all times by reason of the resistance of the piston in the gasoline tube assures a constant supply of correctly proportioned mixture and a wide range of flexibility.



Section of new carbureter on the 18-horsepower Renault

Throttling is now done in the upper portion of the mixing chamber and not in a separate chamber connected up to the intake manifold. The arrangement consists of a movable sleeve 30 on the lower portion of which are a number of elongated grooves corresponding with holes in the cylindrical vessel 31. The internal sleeve is mechanically operated by means of the foot accelerator, and in proportion as it is raised more of its grooves are brought into relation with the holes, allowing an increasingly free passage of the mixture to the chamber 32, and from there into the intake pipe. Control of this sleeve is by means of the foot accelerator from a position giving the slowest possible running on a level road to the maximum speed. Further throttling down is obtained by a small lever placed under the steering wheel, by means of which it is possible to cut off the supply of gas entirely, it being by this means that the motor is stopped. The only occasions on which it is necessary to use the lever is for stopping the motor or for throttling down lower than the minimum given by the foot accelerator.

For ease in starting, a small dashboard lever is fitted by means of which the counterweight 17 can be lowered until it comes in contact with the stem of the supplementary air inlet valve, thus shutting off the supply of additional air and giving a very rich mixture. As soon as the motor has been started the lever is carried over to its original position, allowing the counterweight and spring to operate normally.

Economy in Commercial Vehicle Work

Experience as it gains force in commercial vehicle pursuits offers food for serious reflection in view of the high rate of depreciation when the speed of going is high. As an illustration of the tendency to excessive speed and its ills, it is only necessary to point out that a day or two ago a five-ton commercial car, in New York City, was stopped by a policeman, and the driver was arrested for speeding. This shows that trucks running light speed up to a point which is too high, and the question which is uppermost is how will it be possible to regulate the motor so that it will be unhampered when loaded, and at the same time regulate the speed of the car when it is running light. This is a carbureter problem, and one way is to employ an automatic throttle; but this device is prone to limit the power of the motor just when power is most required. On the other hand, if the gear ratio is increased, the car will run too slow under load, or the motor will race when the load is removed. When the standardization problem is taken up in earnest, the scale of proper speeds for loaded trucks of the various sizes will have to be constructed, but it is believed that a five-ton truck should be geared so that it will not travel faster than 10 miles per hour loaded, and a means should be provided for limiting speed to, say, 12 miles per hour [illegible] the truck is running [illegible]

An Unlooked-For Reason for Overheating Motors

By THOS. J. FAY.

Discusses over-heating problems of motors, calling attention to the ills of internal incrustation. Gives list of the recognized causes of power losses and heating troubles. Spheroidal condition of the water represents the special point and is introduced as new matter; this condition is described and enlarged upon.

ACCUMULATIONS within the combustion chambers of motor cylinders may be the foundation of many of the heating troubles that are experienced, but there is a class of trouble that is not to be explained away so readily. When motors go into service, and the mark of time is placed upon them, the things that the owner will have to cope with are usually stated as follows:

(A) Loss of compression due to leaky piston rings;

(B) Leakage which comes when the bore of the cylinders becomes out of round;

(C) Defective ignition following, (a) spark-plug trouble, (b) battery failure, (c) magneto imperfections, (d) spark-coil deterioration, (e) wiring deterioration, (f) lost motion in the spark manipulating mechanism, (g) poor timing, due to wear of the valve mechanism, or for other kindred reasons.

(D) Defective carburetion following, (a) poor fuel, (b) improperly adjusted carbureter, (c) lack of fuel due to low or variable pressure in the gasoline tank, as when the piping is defective, or if the pressure valve is out of order.

Fuel trouble may also be extended to include leakage of air into the system between the carbureter and the combustion chamber, due to poor joints in the intake-manifold.

(E) Pre-ignition following, (a) accumulations of carbon, silicon and ash from the lubricating oil, (b) when the temperature increases beyond the working level, due to lack of efficiency of the cooling system.

(F) The usual reasons why the cooling system fails to work satisfactorily are given as follows: (a) leakage in the pump, (b) incrustation in the radiator, (c) plugged-up piping or passageways.

Spheroidal Conditions of the Water Not Included

It is well understood that incrustation is difficult to prevent; it comes when solid matter suspended in water is precipitated as it will be if the water is heated up to a certain temperature, and even in the most perfect cooling system the temperature of the water is high enough to precipitate certain portions of the solid matter which abounds in the average water of the "potable" classification.

This condition leads to the formation of scale all over the water surfaces of the cooling system, and to some extent, on this account, all the cooling surfaces reduce in value as the crust accumulates. To discount this growing condition it is necessary to afford a liberal area of cooling surface, which is the custom among designers of skill.

But if this part of the problem is handled with skill, and judgment is given vent the fact remains that the "spheroidal" question is ignored.

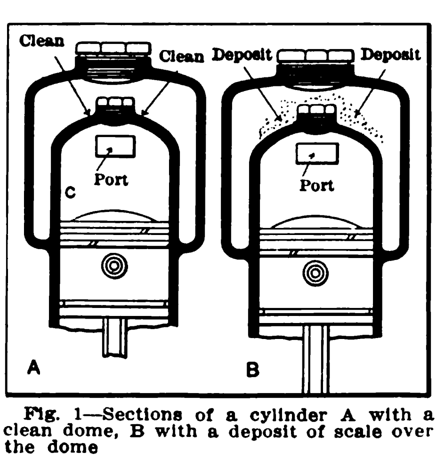


Fig. 1—Sections of a cylinder A with a clean dome, B with a deposit of scale over the dome

Referring to Fig. 1, of the exterior dome of a cylinder, just at the zone of greatest heat, (A) shows the condition as it exists in a new motor, and (B) is the condition which follows considerable service. When the motor is first put into service the exterior surfaces are clean, and the transfer of heat is at such a good rate that the spheroidal phenomenon is not manifested. In time, and as the extra heat at this point causes heavy precipitations of the solids in the cooling water, as shown in (B), Fig. 1, the exchange of heat is so much retarded that the walls of the cylinders, over the hottest part, reach a higher temperature than when the motor is new, with the consequent result that spheroidal action does take place, after which heating trouble is difficult if not impossible to avoid, and the power of the motor reduces materially, even if preignition does not take place.

What Is Meant by Spheroidal Action

When a plate is highly heated and water is then spilled upon it instead of the water contacting with the plate and absorbing the heat, the water is repelled and the plate is isolated by spheroidal fluid. The bombardment of the sheet of water by radiant heat is sufficiently fierce to prevent the water from wetting the plate, and the water, under the force of the bombardment, is broken into spheroidal particles, in which shape it floats in the space above the plate, creating a turmoil along the compacted globules, and the observer, noting this turmoil, generally satisfies his own curiosity when he reaches the conclusion that "the water sputters off of the heated surface."

That the water does not reach the plate at all, is not taken into account, but such is the case; what does transpire is that the spheroids of water float on a layer of vapor which forms between the plate and the water. The temperature of the spheroidal group is below the boiling point of water, although the plate, not being cooled by the water, but being heated continuously on the opposite side, continues to heat up, and the spheroidal phenomenon is aggravated. Grease, if it coats over the surface, will excite this condition, but scale is also a prime cause.

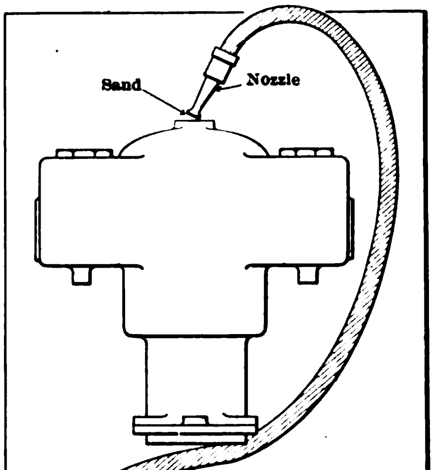

Fig. 2—Cylinder with the cap off showing the nozzle of a sandblast directed against the dome to remove scale

It has been found that when a plate is overheated a spheroidal layer of water, even several inches thick, may be repelled and supported by the vapor layer which intervenes. Under such conditions the temperature of the plate may be over 1,000 degrees Fahrenheit, notwithstanding which fact the spheroidal formation of the water will be below the boiling point of water.

Remembering that solid matter is precipitated more readily at the higher temperatures than it is when water is maintained at a low temperature, it is readily explained how incrustation will be in a thicker layer on the exterior surfaces of the combustion chamber, and, since this scale will induce the spheroidal phenomenon, it is a plain deduction that, no matter how much water there may be in the cooling system, or how fast it is circulated, it will do almost no cooling work at all after the spheriodal condition, with its consequent defects, creeps in. In view of the premises it is possible to see how a cooling system can exist in which the water will be quite cool and at the same time the motor will be overheated.

Loss of Power Is Bound to Follow

When the cooling water assumes the spheroidal formation over the dome of the combustion chamber of the cylinders, the condition of overheating which will then be present will be manifested in loss of power; the motor will lose its ability to quick response, and its torque will fall below the proper level. The weight of fuel which may be taken into the cylinders under these conditions will be lower than when the temperature is properly adjusted, due to the increasing volume of the mixture as it contacts with the overheated surfaces, and, to whatever extent liquid fuel reaches these overheated surfaces, it will "crack" and a further deposit (in this instance, on the inner surfaces) will be accumulated. This way of reasoning leads to a very important conclusion, i. e., combustion chamber trouble, due to carbon deposits, may follow spheroidal trouble in the water circulation.

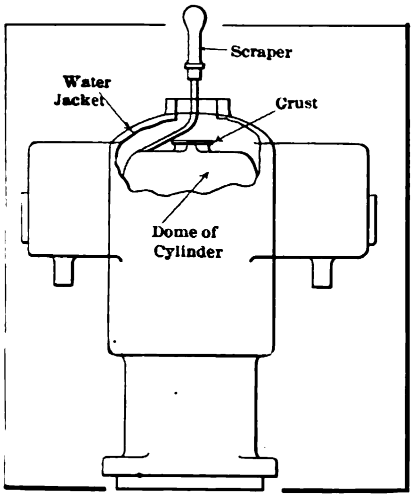

Fig. 3—Cylinder in part section with the cover off showing a scraper in position to remove scale

The remedy to apply is, of course, very simple; scrape the scale off of the exterior surfaces of the cylinder all over the portion that has flame in contact with the inner walls.

This will be possible of accomplishment if the surfaces to be scraped are accessible, as they are in one way or another in substantially every motor made. In some cases it is easier to apply the "sand blast;" in others the covers are large enough so that when they are removed a scraper may be used directly; in other designs a curved scraper may be inserted through the holes that are used for the water piping. Fig. 2 shows the application of the sand blast. Fig. 3 depicts the use of the curved scraper and Fig. 4 is a design which affords a large opening which permits of using a scraper directly and allows of inspecting the surfaces to be cared for.

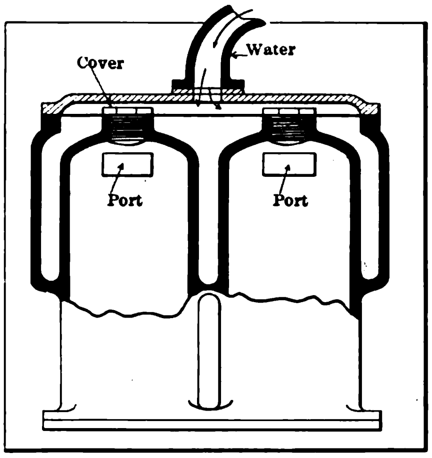

Fig. 4—Section of a twin-cylinder designed with an open jacket fitted with a cover which may be readily removed for scraping purposes

Foundry Advantage Connected with Open Designs

Disregarding the question of spheroidal action, due to accumulations over the dome of a cylinder, there is another point that is well worth taking into account; it relates to the production of cylinders in the foundry. The gases which form during the moulding process must either be permitted to escape or the metal will be defective, due to the migration of the gases through the freezing mass, after teeming. This difficulty is entirely overcome in the class of cylinders which are designed with plenty of opening such as is brought about by having covers as shown in Fig. 4. In some cylinders the openings are on the side, but in view of the possibility of trouble from spheroidal action, it would seem as if the openings might best be just where they will permit of inspecting and teeming the exterior surfaces of the dome. The cost of cylinder production is decreased if "wasters" are reduced to a minimum. This advantage is more nearly assured when the design is such as to permit of the escape of the gases.

Conditions at the French Capital Reviewed

PARIS, July 7—Automobile road races having ceased to interest, and the Grand Prix of the Automobile Club of France having come to an untimely end, the club announces the creation of a Grand Prix to be competed for in the air. In reality, there are two Grand Prix, one for aeroplanes and the other for dirigible balloons. The heavier-than-air machines must start from Issy-les-Moulineaux, at the gates of Paris, fly to the plain of Eterberck, in the suburbs of Brussels, and return to the starting point at Paris. The journey must be made with a passenger on board the machine, the two persons weighing together not less than 330 pounds, part of which can be made up by non-consumable ballast. Attempts to win the prize can be made on any day up to January 1, 1911, the winner to be the pilot who has covered the distance in the shortest time. He will receive in cash $20,000, the second fastest taking $6,000, and the third $4,000.

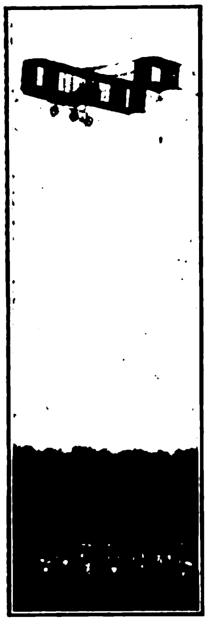
There is only one fixed landing place on the journey, namely, at the extreme outward point, where three hours will be allowed to fill up fuel tanks and get away again. If this time is exceeded, it will be counted in the elapsed time in the air. Landings can be made at any desired spot on the route, but as no time allowance will be made for them aviators have an interest to make them as few and as brief as possible. In a straight line Brussels is 165 miles from Paris, thus giving a total distance of 330 miles, which must be covered in not less than 36 hours. All pilots qualified by the International Aeronautical Federation are entitled to take part in the race.

The airship Grand Prix is less difficult than the task set the aeroplanes. Starting from the plain of Vincennes, on the eastern suburbs of Paris, a trip must be made to Rheims, 93 miles away, a passenger landed and taken on board again, and a return made to the starting point at Paris. No time limit is fixed for the 186-mile journey. There is only one prize, of $10,000, to be awarded to the pilot of the airship making the fastest trip from the present date to January 1, 1911. It is evident from the conditions for the two races that the Automobile Club of France has more faith in the rapid development of the aeroplane than in that of the dirigible balloon.

In England the *Daily Mail* has announced a similar competition, to be held during the month of July, 1911. A prize of $50,000 is offered to the pilot of the aeroplane making the fastest round trip of nearly 1,000 miles, starting from London and passing over the following towns: Harrowgate, Newcastle, Edinborough, Stirling, Glasgow, Carlisle, Manchester, Bristol, Exeter, Newport, Brighton, Tunbridge Wells, and London. A landing will have to be made within a certain distance of [illegible] of the towns.

Studies in Aviation Theory and Practice

By MARIUS C. KRARUP



WHEN the power has given out and the wind and gravitation are playing with the aeroplane, it is the property of fundamental stability—independent of speed and control-action—which must be depended upon for placing the machine in the proper position for a safe descent by gliding, while it is altitude—which is only another word, in this connection, for stored gravitation power—which will give choice of landing place. It is true that, if momentum is left when the power gives out and no unfortuniate gust throws the machine around to a position where the momentum becomes useless as a basis for control, and if the aviator is quick enough of decision to make use of this momentum, then he can utilize it by means of his tilt-rudders so as to assume the tilt at which gravitation will take the machine down in safety, even if its stability has not been nicely calculated, but in practice a number of aeroplanes have been known to go over backward, helplessly, under conditions which were reported to be by no means unfavorable, so far as the force and regularity of the wind were concerned. Probably the art of instilling stability in aerial craft will long remain subject to judgment and skill, rather than to definite and scientific rules, because all exact data are as yet lacking with regard to the degree of stability that is desirable and also with regard to the effects of wind action which attacks the surfaces of the machine at irregular angles, but it seems to be established, in accordance with the foregoing, that the natural stability should be of such nature that the machine suspended in a calm atmosphere, without motion in any direction—if this may be imagined—would have its planes pointed for a glide or perhaps a little more downward. This also seems to be acknowledged in the more advanced position given to motor and propeller in recent European machines, which were previously especially liable to the backward tumble.

With a control apparatus permitting changes in the tilt of the main plane or planes, with relation to the bulk and load of the machine, the central or rest poise of stability could probably be more nearly horizontal, as it would be in the aviator's power to give the planes the gliding tilt by control action, whether rudder action had ceased to be effective or not.

In designing stability into an aeroplane of the common types, the first thing to be thought of would now be to see that the center of air pressures under the planes during flight, at various speeds, came so far in front of the center of gravity of the machine, as a whole, as to lift the latter from the gliding to the flying poise. (It is very fortunate that speed does advance the center of sustentation.) The next consideration would perhaps be to determine how low the center of gravity might be placed without giving too much work for the rudders in effecting or maintaining a change of direction, and, as data are missing and rudder efficiency depends largely upon speed, the designing would needs be entirely empiric.

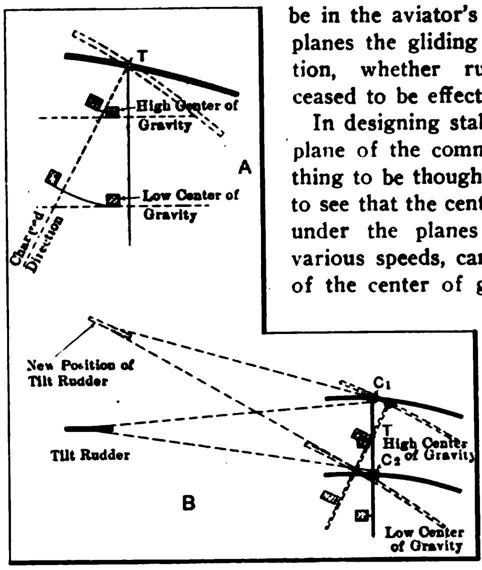


Fig. 1, A and B—Illustrating difficulty of control with low center of gravity, A in monoplane, B in biplane

In Fig. 1, *A* is indicated the action of changing direction with a monoplane. *T* is supposed to represent the transverse axis of air pressure under the plane, and the motion practically takes place around this axis, as the whole machine is suspended from it. It is readily seen that, for a given deviation, as indicated by the dotted line, the low center of gravity must be moved and raised more than the high center of gravity. And the condition would not be different, so far as the effort of the control movement is concerned, if the new direction were downward instead of upward, as in the sketch. Fig. 1 B indicates the condition with a biplane. Here there are two axes of air-pressures and support, C_1 and C_2, and the machine is turned around *T* midway between them. The action is practically determined by the tilt rudder moving upward, and the difference in the sensitiveness of a given control apparatus, accordingly as the center of gravity is high or low, is even more pronounced than in the case of the monoplane.

The weak control resources in the customary machines, both biplanes and monoplanes, seem to leave small chance for increasing stability much by lowering the center of gravity without interfering strongly with the efficiency of the control apparatus, but in practice it has become desirable to carry two or three persons occasionally, and this involves a considerable lowering of the center of gravity, in nearly all instances, and consequently, there has been witnessed a steady increase in the sizes of the control areas, particularly those of the tilt rudders, which bear the brunt of the work of shifting a low center of gravity into a new position. Preferably a load which is not always carried should be placed so as to leave the height of the center of gravity unchanged, as in this manner the efficiency of the control movements will be least affected.

The most difficult problems with regard to the stability enter in the consideration of the surfaces. To place these so that they normally afford sustentation and at the same time so that a disturbing wind action, which changes their positions, will get a poorer rather than a better purchase upon these surfaces the more they are turned from their normal angles, is a practical problem which it does not seem possible to illustrate in any other way than by analogies and examples. But it seems clear, to start with, that a good stability is not consistent with any arrangement by which a disturbing influence which causes the machine to be tipped to one side, by this very tipping gains a stronger disturbing influence; and it seems equally certain that the location of the center of gravity in relation to the various surfaces must be so low that no tipping will cause gravitation to work against the resumption of the normal poise.

The supposition in this article is constantly that only the fundamental stability which acts independently of speed and control action is referred to. Fig. 2 illustrates the basic ideas with which the designer has to do his thinking. *A* is a hollow sphere of light weight. Falling in the atmosphere, it eventually reaches a speed at which the air resistance equals its weight. It can fall no faster. *B* is another hollow sphere of the same diameter and surface as *A*, but heavier, say four times heavier. Falling, it can reach twice as high a speed as *A* before the air resistance will stop further increase of its speed, because doubled speed creates a four times higher air resistance. The relations are indicated approximately by the arrows and dotted horizontal lines. Both these spheres may fall without turning around. *C* is a hollow sphere, heavier on one side than on the other. The heavy side *w* will tend to fall faster than the light side *a*, the air resistances, which depend on the surfaces, being equal, and *C* will therefore reach its constant falling-speed in the position of *C2*. Its equilibrium is upset, compared with the position of *C*. In reality its true equilibrium has been found. *C2* has natural stability, while *C* has not. Yet *C* may be propelled through the atmosphere in the direction of *a-w* and remain in equilibrium so long as the horizontal speed is maintained, but no longer. *D* is like *C*, except that an area *a2* which creates air resistance has been added on the heavy side *w*. In what direction this body will fall, and how far it will fall before its speed reaches its maximum, and in what position it will then be, depends upon the air resistance created by *a2* in the various positions which this area member may assume under the influence of the gravitation of *w*. A curvature or concavity in *a2* may considerably affect the position which *D* will finally take.

With the aeroplane, whose relations between weighty and surface portions is much more complicated than those of *D*, it is necessary, however, to know in advance that the poise of the machine in the air will remain one in which the aviator can keep his seat and also to know the maximum vertical speed at which the machine can fall in any position which it may assume. Perfect stability should probably involve a choice of going down vertically as an unfolded parachute, save for such deviation from the vertical as the wind may cause, or obliquely by adding a control movement of the surfaces.

Colonel Renard found many years ago by experiment that a hollow hemisphere moved with its hollow squarely against the air at a certain speed met a resistance of 109 as compared with a resistance of 33 when moved with the convex surface foremost, and it has since been ascertained that the same body moved obliquely, as illustrated in Fig. 3, meets a total resistance which at some angles is higher than 109 with the hollow foremost, while it is always less than 33 with the convex side foremost.

Much more elaborate experiments with plane, concave and convex surfaces and bodies have furnished some data which further complicate the problem of automatic stability in the wind with fixed surfaces, while supplying the thought-material from which control surfaces must be designed.

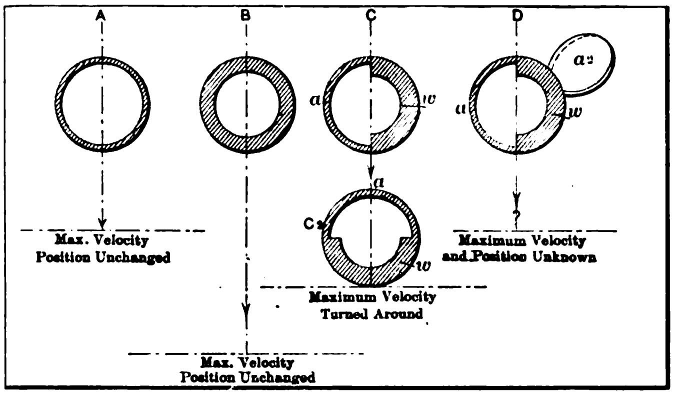

Fig. 2—Illustrating principle of automatic stability in the air

Comparing A and B in Fig. 4, in which A represents a monoplane in front view, edge view and with the lateral equilibrium disturbed, and B a biplane in front view and with the lateral equilibrium disturbed, it is seen at once that the heavy portion *w* in A has a better chance for returning to its normal position than *w* in B, the small circle representing the center of gravity.

In both cases it is a drawback that the gust, from the side and a little from below, which has caused the disturbance, gains in upsetting power when the plane's angle with the direction of the wind is increased, until a maximum effect is reached at an angle of about 25 degrees, which is not a comfortable lateral tilt for the aviator. And the lateral stability is under these circumstances the opposite of progressive. As the machine is normally advancing in space at the same time, the biplane will seldom get an advantage in this respect by having the lower plane taking the wind from the upper one, and altogether it seems difficult to find a remedy without having recourse to control or introducing elastic elements in the planes which will change their shape automatically under the influence of the surplus lift which causes the disturbance. In C the so-called dihedral angle is introduced in the biplane and, if the wings with this design were held normally at angles approaching that which gives maximum power to the disturbing side wind, the disturbance would at least not gain in severity by its own action.

(*To be continued.*)

Testing Steel—For Impact, Bending, Etc.

By BERTRAM BLOUNT, W. G. KIRKALDY and Capt. H. RIALL SANKEY

(*Third Installment*)

Detailing the arrangements for measuring the time-interval between the anvil and bottom contacts in subjecting specimens to breaking tests; also explaining the machine and the manner of carrying out the repeated-bending tests.

IN THE breaking of the specimen the energy absorbed is determined by the expression:

$$\text{Energy absorbed} = W \left\{ H - \frac{1}{29}\left(\frac{h}{t} - \frac{9t}{2}\right)^2 \right\}$$

where H is the height of free fall before striking anvil;

h is the height of free fall after striking the anvil, *i.e.* between the anvil contact and the bottom contact;

W is the weight of the tup; and

t is the time-interval between the anvil and bottom contacts.

The arrangements for measuring the time-interval are as follows:

Easily opened switches are placed at *a* and *b*, Fig. 2, and complete an electric circuit. As the front edge of the tup passes these switches they are momentarily opened and the circuit is broken for a very small fraction of a second. A recording pen, marking a continuous line in a paper band, Fig. 4, Plate 1, is thereby deflected, and the distance between these two "deflections" is a measure of the time-interval. The paper band is unrolled by means of an ordinary Morse telegraph "inker," altered so as to get a much more rapid unrolling of the paper; 5 inches a second has been found to be a suitable speed for the paper. A second recording pen, vibrating at about 40 per second, marks a "corrugated" line, but to calibrate these corrugations and to obtain an absolute standard, half-second marks are recorded by means of a half-second pendulum—which was compared by Mr. G. P. Mair with the pendulum of a clock whose rate is 2 seconds per month. A fac-simile of a record is given in Fig. 5, and it is computed from numerous observations of free fall that the error in the time interval measurement is less than 0.005 second.

The method of making a test with this impact testing-machine is as follows: The test-piece having been fixed into the grips, thus connecting the cross-arm and the tup together, the whole is hoisted up and fixed to the stretcher by means of the releasing catch. The paper band is then started and so soon as the speed of the paper is constant (which requires a few seconds) the catch is released, and at the moment of release the electric circuit of the recording pen is opened and the first time record is marked on the paper. Immediately after breaking the test-piece the second time record is marked by the opening of the

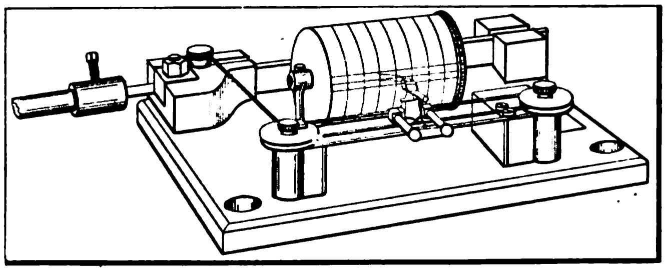

Fig. 6—Repeated-bending machine

anvil contact, and the third by means of the bottom contact after falling another 10 feet. In a similar manner the time required for the free fall from the point of release to the anvil can be determined and a check is thus obtained, as this interval of time should be equal to the time of free fall in air due to the action of gravity.

The degree of accuracy obtainable in the measurement of the energy absorbed by the specimen is mainly dependent on two things, namely, (*a*) on the ratio of the kinetic energy remaining in the tup after breaking the test-piece to that it possessed at the moment of striking, and (*b*) on the error in the measurement of the time-interval in falling the distance *h* (10 feet) beyond the point of rupture. The matter was investigated and an abstract of this investigation is given in the Appendix (page 30). It need only be mentioned here that the percentage error in the determination of the absorbed energy will be about half of the percentage error in the time measurement, if the remaining energy in the tup does not exceed two-thirds of the energy in the tup at the moment of striking the anvil. With an unknown specimen, however, a considerable margin must be allowed to ensure breaking the specimen with one blow, and it may be, therefore, that the proportion of energy remaining to initial energy may be considerable, and then the percentage error in the determination of the absorbed energy will be greater than the percentage error in the time-measurement. It should be noticed also that if the remaining energy is very considerable the percentage error in the absorbed energy would be excessive, but in practice a rough estimate of the strength of the specimen can be made so as to avoid such errors. If several similar specimens are to be broken, the weight of the tup or the height of fall (preferably the former) can be adjusted after breaking the first specimen. Based on general consideration and as the result of some preliminary trials, a height of drop of 30 feet was adopted for these tests.

Capacity of the Machine.—The machine has been so designed that a 40-foot drop with a 20-lb. tup can be used. The available striking energy is therefore 800 foot-lbs., and this energy is sufficient to rupture a steel test-piece ⅜ inch in diameter.

Repeated-Bending Tests

The repeated-bending machine used in these tests is shown in Fig. 6, Plate 1, and it automatically records the number of bends and the bending effort of each bend. The test-piece is 4 inches by ⅜ inch diameter, and one end is fixed in a grip carried by a flat, steel spring, the other end is inserted into a hole in a lever and is secured by a cup-ended screw. This lever is 3 feet long, and by its means the test-piece can be bent backwards and forwards. When a force is applied to the lever the first action is to deflect the flat spring, and this deflection will increase in amount until the test-piece begins to yield, after which there will be no further deflection of the spring and the test-piece will be bent. The bending is continued until the maximum angle of bend is reached, which has been chosen as 46 degrees after much preliminary work. The direction of bending is then reversed, and the flat spring is deflected in the opposite direction. The bending of the test-piece is continued beyond the original central position until an angle of 46 degrees on the opposite side is reached, then the direction of bending is again reversed. This process is continued until rupture occurs.

The grip at the end of the flat spring is connected by a wire and a multiplying arrangement to a recording pencil carriage working on guides. The wire attached to this carriage is kept taut by a spring placed in a circular box. The motion of the pencil is recorded on a paper placed around a drum and is proportional to the deflection of the flat spring, and therefore, obviously, to the bending effort. The drum is under the action of an internal spring and rotates a definite distance each time a bend is started from left to right, and in this manner the number of bends is automatically recorded as shown in Fig. 7, which is a fac-simile of a record. The papers are ruled with lines giving the bending effort expressed in lb.-feet. One bend is reckoned as bending from the extreme position on the right to the extreme position on the left, or vice versa. Hence, the first line of the record, namely, AB, Fig. 7, which is drawn whilst the test-piece is being bent the first time from the central straight condition to the extreme position on the left, represents only half bend. Since the distance between the lines representing the record of the bends is proportional to the distance travelled by the bending force, the energy required for one bend is obviously represented by the rectangle drawn to the left of each line, as AEDC, for example. For AB, however, the rectangle is only half the width, since this line represents only half a bend. The test-piece generally breaks before completing a bend, and a graduated quadrant is provided to measure the amount of the last bend expressed in tenths of a bend. Hence, the rectangle representing the energy of the last bend will have a width the same number of tenths of the full distance between the lines, as shown by rectangle GHKL. Finally, the total energy required to break the specimen is given by the area included within the dotted line, Fig. 7. In the original record one square inch represents 400 foot-lb. of energy, so that it is easy to calculate the energy, expressed in foot-lb., required to break the test-piece.

Fig. 8 shows nine records of Repeated-Bending Tests, reduced half-size.

Results of the Tests

The average of the principal observations are given in Table 1, and it will be noted that two sizes of tensile test-pieces are quoted for each type of steel—the dimensions of the small test-pieces are the same as those of the impact-tensile test-pieces. In the case of steel for tires (Item No. 12) there are three sizes of test-pieces—that having a diameter of 0.564 inch being the standard size. It will further be observed that in general the tensile results are higher for the small test-pieces than for the large, which is probably due to the metal in the smalled test-pieces being more worked, having been taken from a position nearer the skin.

In the impact-tensile tests the means of the observations on three test-pieces are given. As regards the energy absorbed by the rupture of the test-piece, which is the important measurement in this test, the readings agree fairly well, the average disparity from the mean being about 6 per cent., but in a few cases the disparity is as much as 12 per cent., possibly owing to the position in the material from which the test piece was taken.

Rejuvenating the Old Automobile

By G. J. MERCER

Illustrating a remodeled Buick, changing the old touring body to a new fore-door type, showing enough details to permit a body maker to do the work and specifying the character of the materials required, also the methods of procedure necessary to complete a first-class job, with some timely hints as to finishing.

THIS undertaking involves a Model 17 Buick, using the old body with just enough alteration to permit of the addition of the fore-door, changing the dash in order to make the front finish agreeable to the eye, and to give room for the wing of the door. Fig. 17 is a side elevation of the car, showing the flare of the mudguards and the manner of their installation for the purpose of protecting the body from picked-up mud, also the running board and the metal work between it and the body sill. Fig. 18 shows the new fore-door, and the dotted lines are for the purpose of telling the workman how to frame the same. Fig. 19 is a front elevation showing the shape of the radiator and dash, also the outline of the body back of the dash. The aluminum panel, the metal of which is No. 16 gauge. The moulding is continued around to the point *A* on the panel edge; it joins the moulding on the seat. In Fig. 19 the hooded dash is shown, and its relation to the hood or bonnet is indicated. The corners of the dash hood are slightly rounded at the front. This rounding ends at the front of the door, and the right side is framed in the same manner as the left, making allowance, however, for the cut of the door on the left side only. The change levers, as shown in Fig. 19, must be bent out slightly to give clearance at the top, but the bending should be done at a point near the quadrant, leaving the levers straight from the point of bending out to the handle. The door opens from the back, the side levers come to the outside of the body line, the quadrant being quite high up, and so far out from the face of the chassis frame that it becomes desirable to bring the levers to the outside. Fig. 20 is a plan of the front end of the body from the dash line to a point back of the fore-door.

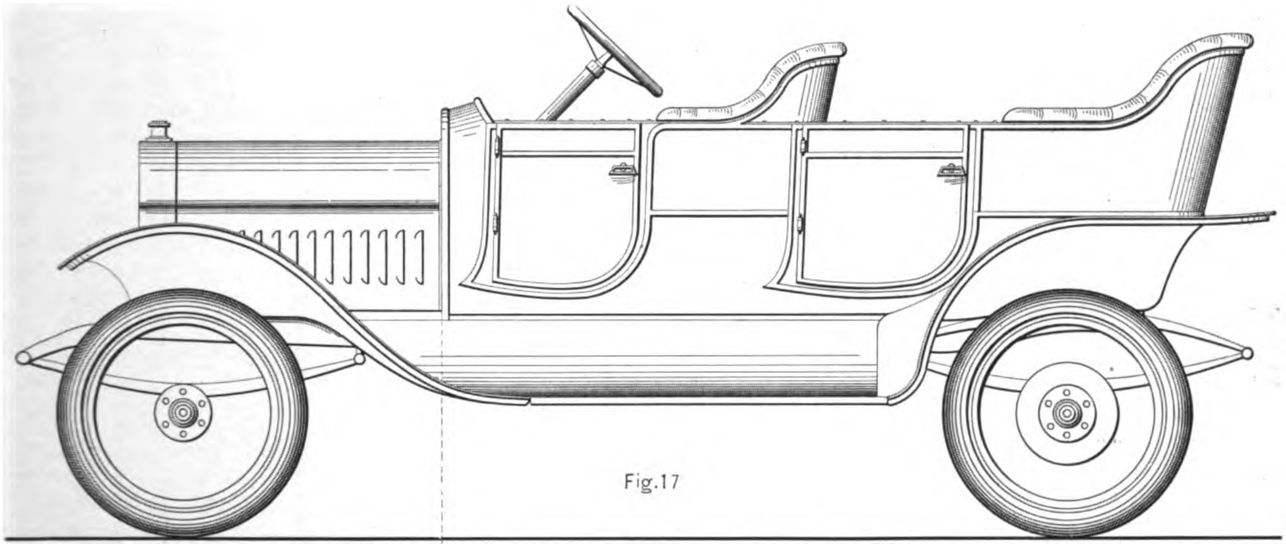

Fig.17

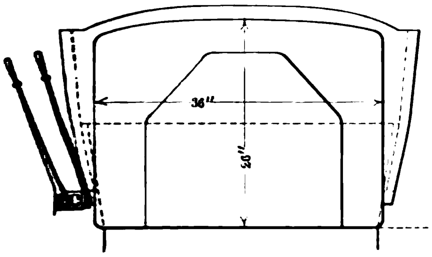

Fig.19

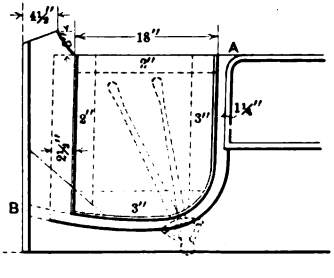

Fig.18

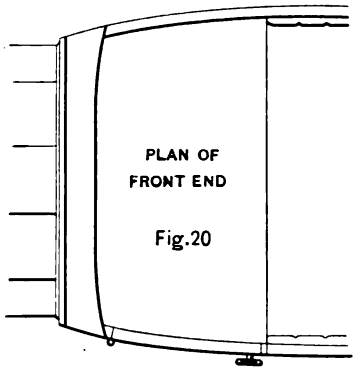

Fig.20

Fig. 17—Model 17 Buick, with new fore-door type body replacing old touring style. Fig. 18—Detail of new fore-door. Fig. 19—Front elevation. Fig. 20—Plan

The left fore-door corresponds in shape with the rear door on the side view, but the right side is merely provided with an imitation door; the levers being in the way would prevent a door from swinging out. It is optional with the owner to have the fore-door permanently hinged or to so swing it that it may be detached during periods of fine weather. The pillar effect at the front of the door is formed by moulding riveted to an swing being high enough up to prevent interference with the mudguards, and the hinges, as well as the handles, should be selected to conform with the style of fittings used on the old body.

The amount of work required to bring this body up to the new style as shown is very limited, and it is reasonable to expect that the alterations could be carried on in a repair shop of no great pretense. With the body work completed, it would be proper to have the same removed to a finishing shop, with a view to having the old part of the body prepared for painting, so that when the new finish is applied, the appearance would be uniform over all of the surfaces.

Superstructure Too Close—Damages Tires

Editor THE AUTOMOBILE:

[2,324]—I wish to complain about the careless manner in which bodies are put on to the chassis frame. In my car I found that in going over "Thank-you-marms" the body comes down onto the axle, but the clearance between the body and the axle is less than the clearance between the tires and the mudguard. I have since put rubber bumpers on the top of the spring perches to prevent the body from coming down so far, but I think this detail in automobile designing should be given some attention now that makers claim that they have put automobile designing upon a standard basis. READER.

Akron, Ohio.

We do not think that the tires were cut in the simple process of rubbing, which is all that would happen under the conditions you name, unless, as shown in Fig. 1, the mudguard bolts come just at a point where the tread contacts, and the protruding bolt tears the tread of the tire. In bringing out the point you make, it is the purpose here to add this additional information, which was taken from life.

Some Characteristics of Wipe-Spark Systems

Editor THE AUTOMOBILE:

[2,325]—I understand the performance of jump-spark systems of ignition, and how the voltage grows until it becomes sufficiently strong to leap across the contact points on the spark plug. I would like to know, however, the difference between this and the condition involved in wipe-spark work. M. A. E.

Chester, Pa.

The low-tension magneto, as used in the type of ignition to which you allude, is not designed to deliver a sufficient voltage to jump a gap. The spark is obtained by drawing an arc, and the method in vogue is illustrated in Fig. 2, which shows the arc light carbon pencils A, B, C and D, just as they are used in an ordinary arc lamp for street lighting. At A the two carbons are separated about 1-8 of an inch. When it is desired to light the lamp, the circuit is closed by a switch and the carbons come together, as shown at B. This operation closes the circuit, and the electrical current is set up, after which the carbons are pulled apart by an electro magnet, as shown at C, thus drawing the arc. As the carbon pencils waste away the arc increases in length and assumes the appearance as indicated at D. It is a fact that while the low voltage will not jump a gap, it will nevertheless draw out for quite a long distance, if the contacts are first made and then separated. The current, as it flows across the gap, as it is increased in length, casts off minute particles of the conducting material, forming a gas, the resistance of which is very much lower than the resistance of an air gap. In the wipe-spark system of ignition this principle is taken advantage of, with the result that the energy in the spark is very high, but the voltage of the magneto does not have to be more than probably 125 volts maximum. It is claimed as an advantage of the low-tension wipe-spark system that it affords a high-energy spark, and a low voltage with which to cope from the insulation point of view. It will be understood, of course, that if the insulation of the system breaks down, the service will be interrupted.

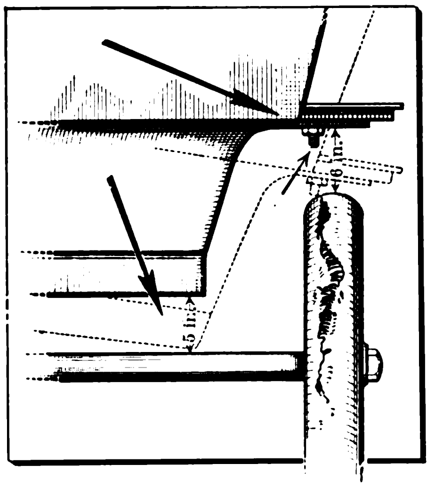

Fig. 1—Lack of harmony of the clearance relations, there being too little between wheel and mudguard

Looking Around for a New Type of Battery

Editor THE AUTOMOBILE:

[2,326]—In order to obviate the necessity of having to deal with troublesome acid solutions as they are used in certain types of batteries, it is my understanding that dry cells are given preference by many autoists. In counting the disadvantages of these types of batteries, it is not too much to say that it is quite an undertaking to carry them to some place for the purpose of having them charged when the occasion requires, and in view of their characteristics they seem to require charging at least once or twice during a season. The dry batteries offer their own character of trouble in that their capacities are relatively limited, and I have in mind the idea of building a primary battery of some kind, one that I can charge myself by simply emptying out the depleted solution and replenishing the cells by no more troublesome a process than adding chemicals and perhaps water. Will you please give me an inkling of the possible success attending an effort such as this? IMPROVER.

Little Rock, Ark.

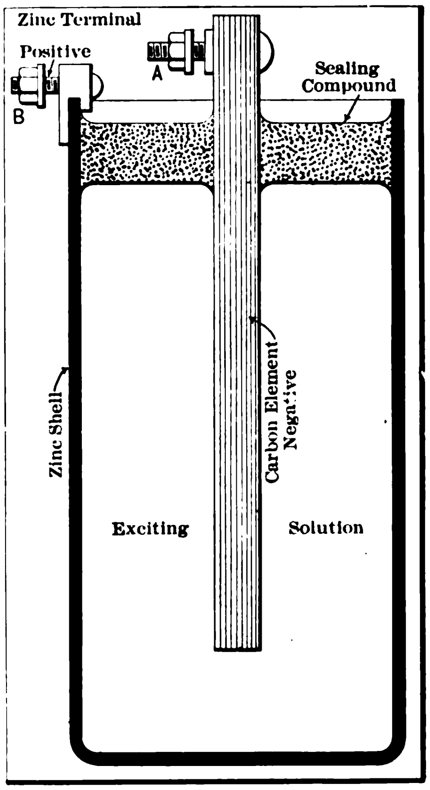

Fig. 3—Single solution gravity battery which is the principle of the dry cell

Local action stands in the way of success with almost every form of primary battery. Fig. 3 shows the dry-cell type of battery in section, with a zinc shell and a central carbon element immersed in the exciting solution. This excitant, instead of being in liquid form, as sal ammoniac and water, is in a semi-hard state. With this type of cell, considering the use of depolarizer, local action is reduced to a negligible quantity, which condition is influenced through the use of pure zinc. Any attempt to depart from this type of cell in the direction of primary batteries leads to local action sufficient to destroy the possibilities, excepting in the types of cell using double solutions and a porous cup between, as shown in Fig. 4. With two exciting solutions, using zinc and copper as the electrodes, if a porous cup intervenes, it is possible to obtain very good results, but it has not been shown thus far in ignition work that a mechanical structure can be improvised, the nature of which will make it fit to withstand the jolting it would receive on an automobile. In Fig. 4, if zinc and copper are used as electrodes, solution A would be sulphate of copper, and solution B sulphate of zinc.

Effect of Weight on Life of Motors

Editor THE AUTOMOBILE:

[2,327]—Will you please answer through your columns, the following inquiry, if possible, citing authorities on the subject. Does the weight of pistons or connecting rods bear any relation to the liveliness or lagging of a 4-cylinder motor of say, 4 1-2 x 4 1-2 cylinders? R. J. G.

Lansing, Mich.

It would seem to be a waste of time to look up authorities on the subject of the effect of weight on acceleration. If the piston and connecting rod in the cylinder of a motor are very heavy, since it is true that the mass will have to be accelerated, it stands to reason that more force will have to be exerted in the process, or with a given pressure, more time will have to be allowed.

Automobiles with Counterbores in Cylinder

Editor THE AUTOMOBILE:

[2,328]—Will you please advise me through the columns of "The Automobile" if there are any automobiles made which have counterbores in the cylinders. Why is it that all good automobiles do not have counterbore cylinders?

WILLARD S. REED,
Smyrna, Kent Co., Del.

Nearly every automobile motor is provided with a counterbore at the top of the stroke, so that when the piston reaches the dwell point, the top ring will rest partly on the relieved portion. In steam engine practice, the counterbore is very pronounced, but in automobile work it sometimes amounts to but a few thousandths of an inch, which difference is brought about in the grinding process. It is not necessary to have a considerable counterbore; the good effect will be present with a difference of a film of oil, but enough for one reboring should be present.

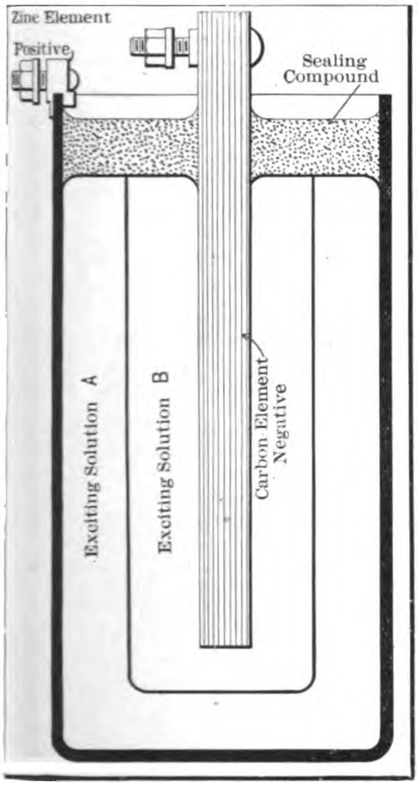

Fig. 4—Double solution cell of battery requiring use of a porous cup to limit local action

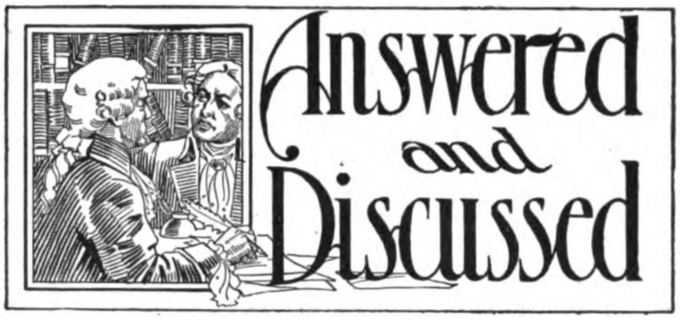
Oil Testing Fraught with Uncertainties

Editor THE AUTOMOBILE:

[2,329]—I am a subscriber to "The Automobile," and would like to ask you through "Letters Interesting" what tests good lubricating oils for water and air-cooled gasoline engine should show, and a simple, sure, and satisfactory method of how to test lubricating oil. All dealers in lubricating oils claim to have the best and only good lubricating oil, and it is so bewildering to the novice that he is at a loss to know what lubricating oil to purchase and use; he is in the dark as to what kind of lubricant to use for his car.

Buffalo Lake, Minn. F. G. NELLERMOE.

It is not believed that an autoist can make any headway testing lubricating oils with a view to proving which of the brands offered by oil merchants are best for automobile work. The plan which would seem to be free from difficulty is to purchase the oil from absolutely responsible distillers, in the original package.



Liquids Will Spill Out of a Receptacle

Editor THE AUTOMOBILE:

[2,330]—I have been reading your "Letters Interesting Answered and Discussed," and get a great deal out of them. I have an 1910 Overland, Model 38; it leaks oil around the brake band and I have tried every way to stop it. The oil comes from the differential. I have packed it several times with felt washers, which stops the leak temporarily. If you can tell me any way to fix it I will appreciate it. B. W. SELF.

Crowell, Texas.

If a half barrel is placed under the spigot and water is allowed to run until the same is filled, and then for a time, the excess of water will pour over the sides and wet everything that happens to be within contact distance. In the same way, if you put too much oil into the differential case the excess will spill out. Anyway, a small quantity of a good grade of semi-hard lubricant will give you less trouble and do the work.

No Sense in Comparing Unlike Things

Editor THE AUTOMOBILE:

[2,331]—I should like to know if the power of a 6-cylinder motor, of say 30 horsepower, is greater than that of a 2-cycle engine of the same power; also if a 4-cylinder motor of the 4-cycle type is superior or inferior in power to that of a 2-cycle, or are they equal? It is claimed for the 2-cycle motor that the continuous torque gives it the same advantage as that obtained from a 6-cylinder motor.

Buffalo, N. Y. E. L. L.

It is highly improbable that there is any way of satisfactorily comparing the performance of a 6-cylinder motor with that which might be expected from a 2-cycle motor which gives the same number of power strokes for a given number of revolutions. There is nothing to be said in favor of the statement that a 2-cycle motor giving 30 horsepower is any better or worse from the power point of view than a 4-cycle motor delivering 30 horsepower. There might be differences involving flexibility, ease of starting, and dependability, but these differences might also be charged to design features which do not have to be adhered to on an equal basis.

Gasoline Consumption Proportional to Power

Editor THE AUTOMOBILE:

[2,332]—Will you kindly advise me, giving reasons, whether a Buick No. 10 will consume more or less gasoline at 10 miles per hour for 10 miles than at 35 miles per hour for 10 miles. I suppose the same solution will apply to any automobile, but a Buick No. 10 is the model under discussion.

W. P. C.
Cincinnati, Ohio.

Since the power required to drive an automobile at 35 m.p.h. is greater than that for 10 m.p.h., the gasoline consumption will be greater when the car is driven 10 miles at a rate of speed of 35 miles per hour.

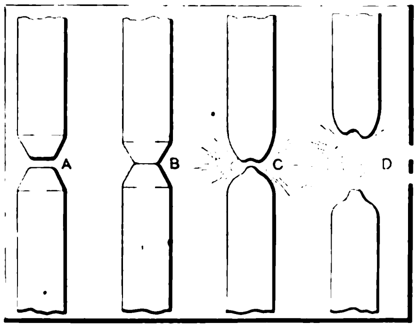


Fig. 2—Arc-light carbons, showing how the arc is drawn

Questions That Arise—General in Scope

Thermal efficiency is improved with high compression; too much fuel leads to indigestion; power is proportional to actual fuel burned to carbonic acid and water; carbonic oxide is representative of waste; limit of compression depends upon method of use of fuel; air must be increased as fuel burned is added to; mechanical equivalent of heat is given.

[165]—What are the advantages of high compression in a motor?

The rate of combustion is more rapid with increasing compression; this has the advantage of aiding in the accomplishment of the useful work within the shortest possible time, and, since the losses increase as the time taken, it follows that the thermal efficiency is better with the higher compression. Again, since the source of all the power of a motor is the fuel value of the mixture, it follows that the more fuel there is in the cylinder for each power stroke the more power the motor will be capable of delivering, provided the motor is not given a dose of "indigestion" by using too much fuel. Increasing compression results in an increased amount of fuel in the space each time, and, since the combustion conditions are bettered by this increase of compression, it is a fair inference that the superior compression does two things, i. e., it packs the space with a higher weight of fuel, and the conditions for burning the fuel are improved.

[164]—Why does increasing the compression add to the weight of fuel?

When earth is rammed around a fence-post to compact it, or when a road roller presses the top coat to a firmer state, the "tamping" process with the post, and the rolling process on the road, are precisely the same in principle as that which takes place when fuel mixture is compacted into a cylinder. There is no difference excepting that it is easier to compress a flexible medium as "mixture" than it is to compact the less amenable clay.

[165]—Are there not some differences to be noted in motors of different makes?

Yes; there are two principles involved in accounting for the good effect of compression. In the "idealized" Otto cycle (4-cycle principle) mixture is drawn in at the atmospheric (or slightly below) pressure, so that the weight of fuel is fixed by the suction stroke; if the suction is at a minimum depression, provided the cylinder fills with gas, the weight will be maximum at a given temperature; if the temperature is lowered the weight of gas will be increased. In the remaining method, instead of "inspiration" on the Otto basis, mixture is put in under separately generated pressure, and the amount of pressure utilized is independent of the suction ability of the piston of the motor.

[166]—What is the limit of compression, and is it the same in both types of motors?

The limiting considerations are not the same in both types of motors. In the Otto cycle, the weight of fuel (total) depends upon the suction ability, but the weight of fuel in the combustion chamber at the instant of ignition (neglecting leakage) depends upon the ratio of clearance space. In this class of motor it is pre-ignition that places a limit on compression, hence upon the weight of mixture in the combustion chamber at the time of ignition. When auxiliary compression is resorted to, provided the fuel is injected separately just before ignition, there is no such limit to place upon compression; it may be as high as mechanical considerations will admit of, unless it is found that lubricating considerations must receive earlier attention.

[167]—Is it necessary to allow more air in proportion to fuel as the compression is increased, or should the air allowance be maintained on a constant basis irrespective of the compression?

As compression increases, so must the air allowance be increased above the theoretically right measure; this is due to the fact that the fuel has less time in which to hunt around for an oxygen mate; it must have its mate if combustion is to take place; it is more likely to find its affinity if an excess of oxygen is present.

[168]—What is the underlying reasoning for this?

Energy resides in carbon, hydrogen and compounds of these elements, as in the hydro-carbon distillates of which automobile gasoline is composed. How to release this energy under advantageous conditions is the problem. This is accomplished by compressing the fuel with a quota of atmospheric air in which oxygen, which is wanted, is a content in the right proportion. The energy in the fuel is set free by combustion, and this condition (combustion) is brought about by mixing the carbon and hydrogen with oxygen, then setting fire to the new mixture.

[169]—What happens when carbon, hydrogen, and oxygen are thus mixed and burned?

The energy residing in the carbon and hydrogen is set free, and the products of combustion are carbon dioxide and carbon monoxide, also water. The carbon monoxide is not desired, but it is formed to some extent owing to the difficulty of supplying the oxygen in such form that it will be taken up by the fuel elements. For complete combustion, then, the final product will be carbon dioxide and water.

[170]—How much energy is there in this fuel?

Automobile gasoline, taking it as an average product, holds about 20,000 British thermal units of heat per pound.

[171]—What is a British thermal unit?

It is accepted as a definite measurement of heat, the latter being a form of energy.

[172]—What is the magnitude of a British thermal unit of heat?

It is that amount of heat which will raise the temperature of one pound of water one degree Fahrenheit, taking the water at its point of maximum density.

[173]—What other way is there for judging the magnitude of a British thermal unit of heat?

It has a mechanical equivalent.

[174]—What is the mechanical equivalent of a British thermal unit of heat?

778 foot-pounds.

[175]—How is this knowledge to be utilized to advantage?

One horsepower is said to equal 33,000 foot-pounds per minute: knowing this, also knowing the foot-pound equivalent of the British thermal unit of heat, it remains to compare one with the other.

[176]—Give an example.

If there is 20,000 British thermal units of heat in a pound of automobile gasoline, and 778 foot-pounds (mechanically) in a British thermal unit it follows that

$$\text{H.P.} = \frac{20{,}000 \times 778}{33{,}000} = 472;$$

this amount of power would be given for one minute; in one second 60 times this power would be the rate.

[177]—What is the specific heat of the fuel elements in gasoline, considering air separately and assuming that there will be a certain amount of carbon monoxide in the mixture?

SPECIFIC HEAT VALUES OF SPECIFIC HEAT OF GASES

	Specific Heat for Equal (Regnault)	
Elements	**Volume**	**Weight**
Air	0.2375	0.2375
Carbon monoxide	0.2370	0.2450
Carbon dioxide	0.2985	0.1952
Hydrogen	0.2359	3.4090
Nitrogen	0.2368	0.2438
Oxygen	0.2405	0.2175
Steam	0.2989	0.4805

The amount of steam present will be limited to the weight of water, (a) entering the cylinder as such, and (b) as represented by water combustion.

Automobiles Constitute Property—Subject to Taxation

By XENOPHON P. HUDDY, LL.B.

AUTOMOBILES constitute property and are therefore subject to taxation. Every person who owns an automobile may be compelled to contribute to the Government his pro rata of taxes based upon the value of the motor vehicle, but the owner of an automobile can be taxed only once for owning a motor vehicle.

The taxation of automobiles as property, and the imposition of license or occupation taxes should be clearly distinguished. License taxes may be imposed by the Government on automobile owners, and are imposed by the States of the United States and foreign governments in the form of registration requirements and fees. When an automobilist registers his car with the Secretary of State, or any other designated officer, and pays a registration fee of a fixed amount, or one based upon horsepower, he pays, not a property tax, but a license or occupation fee, imposed under the police power of the State. This fee is paid for the privilege of using the automobile, and has nothing whatever to do with the value of the machine. Its graduation, however, may be based upon a logical method of computation such as horsepower, which is as accurate as any other known means for the purpose of computing the fee.

Automobiles Taxed as Personal Property

Property taxation of automobiles has not been given any special attention in the United States. Automobiles have not been distinguished from horses, wagons, jewelry, pianos and other personal belongings, but would it not be more just to automobilists and to the Government to separate the class of personal property composed of automobiles from other personal belongings, and to tax it in a distinctive manner?

In law personal property is deemed to be located where the owner thereof is domiciled, even though the actual physical situation of the property may be in another State or jurisdiction. Most articles of personal property are capable of easy removal, yet until the automobile arrived seldom it was that personal property of large value, unless belonging to a common carrier, was in its very nature transitory and subject to travel from State to State. For the reason that an automobile usually possesses no situs outside of the place where the owner is domiciled, it should not be taxed elsewhere.

Obviously, it would be impossible to assess the owner of an automobile with a tax based upon the cost of the machine. Its fair assessable valuation is a matter which is not easy to determine, since a used car depreciates very fast.

In some jurisdictions the attempt has been made to impose a fairly high registration fee on automobile owners, and in consideration of the payment of this fee the owner is exempt from any other tax, either State or local, based upon valuation. A measure of this kind is in reality an ad valorem tax, since in exempting the owner of an automobile from a property tax in consideration of the high registration fee the law virtually takes care of property taxation in the fee paid for registration. It is very doubtful whether a provision of this kind is constitutional. Certainly, if a State charged a high registration fee, which covered also property taxation against the automobile, no municipality or other local authority could levy a tax based upon valuation.

Whether any State, other than the one the owner lives in, may tax an automobile based upon property valuation depends upon whether the automobile obtains a situs in the other State. If no situs is obtained, then no tax can be levied except by the State where the owner resides, since such a tax would violate the interstate commerce clause of the Federal Constitution. If, however, an automobile is used in a particular State for any considerable length of time it would acquire a situs, and, therefore, would become subject to local taxation as property.

In construing and enforcing the interstate commerce clause of the Federal Constitution the rule has been established by the United States Supreme Court that property actually in transit from one State to another is exempt from local taxation; but, if such propery be stored for an indefinite time during such transit for other than natural causes or lack of facilities for immediate transportation, it may be lawfully assessed by local authorities. In dealing with the power of the States to tax imported goods while in the original packages and in the possession of the importer, it must be borne in mind that the clause of Section 10 of Article I of the Federal Constitution, which provides, in part, that "no State shall, without the consent of Congress, lay any imposts or duties on imports or exports" creates a distinction between goods imported from foreign countries and those brought in from other States of our Union. The word "imports" in this section of the Federal Constitution applies only to articles imported from foreign countries, and is an absolute prohibition of State taxation. A different rule, however, obtains with respect to articles transported from one State to another. In such cases there is no positive prohibition like that against the taxation of imports from foreign countries, and the States have power to tax goods that are brought into this State from other States, if they are held for sale there or for other purposes, giving to the property a situs within this State.

How the Tax on Automobiles Is Computed

The methods adopted of computing a tax are more or less a matter for the discretion of the Legislature. Valuation, the method used in property taxation, is logical. Weight has been urged as a proper and logical method of arriving at the tax which different automobiles should contribute. Under this system an automobile which weighs twice as much as another should pay a tax twice in size. Many logical arguments may be urged in its favor, since the heavier a car is the more it will wear out the public highway.

Horsepower has been the method most generally adopted. The lighter a car is the more power it may have. It must be admitted that horsepower is more or less an arbitrary scale selected for the computing of license fees. Arbitrary legislative action is apt to be tainted with illegality. Whether the Legislature possesses the power to tax automobiles according to horsepower has not been squarely determined. It might be said that there is just as much reason to tax automobiles according to color, which would unquestionably be unlawful.

Again, automobiles may be taxable under what is called a wheel tax. This method has been adopted heretofore in respect to horse-drawn carriages, and little objection can be made to it.

Power of Taxation Is the Power to Destroy

Before leaving the subject of taxation it should be mentioned that the power to tax is the power to destroy. If the Government possesses the power to tax a particular object it can tax that object out of existence. The United States Supreme Court has held that the States cannot tax national banks because if the power exists in the States to do this the States can destroy national banks and can tax them out of existence.

On the question of the power of the States to tax travel or transit the same principle applies. The State Government cannot tax a citizen for the privilege to travel from State to State. In other words, transit cannot be taxed in this country.

Following out the principle that transit cannot be taxed, for if it could be taxed it could be destroyed, a tax levied by the State for the privilege of using an automobile, which is excessive, and which amounts to more than a mere license fee, constitutes a tax on transit and to the extent that the tax is on transit, it is unconstitutional.

Digest Along Technical Lines for the Engineer

Economy in great increase of speed of high-speed tools——Automatic pressure regulation for brakes and drives——Same utilized for automatic gear changes——Synthetic rubber still in the distance——Formula for brakes——New incombustible celluloids——Types of motor buses.

Peculiarities of high-speed steel, bearing on shop economics, form the subject of a richly illustrated article drawn largely from the reports published by E. G. Herbert in *Proceedings of the Iron and Steel Institute* for May 5, *The Engineer* (London) for May 6 and 13 and *Engineering* for May 27. The principal practical conclusion relates to the much increased durability of high-speed steels which is obtained by raising the speed of its work far above the normal for light cuts, the economy being not merely relative as compared with using a lower speed and a deeper cut, but absolute, inasmuch as the tool's edge lasts longer than for the same light cut made at lower speed. The output is increased at reduced tool cost, and the explanation seems to lie in part in the different action of the heat on the tool and on the work. After an analysis of the endurance curves plotted for a tungsten and vanadium steel hardened at 1,200° C. in air, and thereafter completely quenched in a salt bath at 668° C., for the same steel heated to 1,275° C.—which carried its maximum cutting speed from 60 to 70 feet—and a simple tungsten HS steel, the article concludes, referring also to a plain high carbon tool steel previously plotted: Summarizing, these three varieties of steel give, according to the rapidity of the tempering, feed curves or endurance curves with one or two maximums. The second of these maximums is strongly developed in the carbon steel as well as in the high-speed steels by the rapidity of the quenching. The first work maximum obtained at low cutting speed is developed in the high-speed steels by slowness in quenching or in cooling, and in carbon steel by high temperature for quenching. The act of drawing temper of high-speed steel has not yet been determined. A moderate cooling rate, or, with carbon steels, a moderate drawing of temper, gives a curve with two maximums and a very feeble endurance of the steel in the depressions between these points—for cuts at intermediate speeds—and the curves of tungsten-vanadium steel differ essentially from those of simple tungsten steel. No explanation of these depressions is known, and, on the other hand, in order to decide with exactness the practical bearings of the results of these tests, it would be necessary to take analogous curves for tools operated at normal rates in factories, with turret lathes for example. This has never been done and would require special apparatus.—*Bulletin de la Société d'Encouragement,* May. Previous articles on related subject in the *Bulletin* for July, 1909.

Worm gears with automatic regulation of pressures are reviewed by Dr. Wilhelm Rehfus in five issues of *Dingler's Polytechnisches Journal,* ending May 28. The author presents the automatic brakes of this order which are used in the industries, and suggests modified devices with improvements. The pressures obtained by different constructions are developed mathematically. The combination of a worm-actuated end-pressure brake with a band brake, on the principle of limiting the pressure of each by the excess pressure of the other, is given fully. Many mechanical suggestions are offered which seem applicable in solving the problem of automatic regulation of the speed of automobiles—of commercial trucks, for example—though the author does not enter upon these possibilities, but limits himself to description of mechanical elements with numerous illustrations. There follows a description of a proposed worm-gear brake-mechanism without automatic stop, which is calculated with such dimensions of parts that light hand or foot pressures are sufficient to absorb enormous brake moments without complicated levers and rods. The same construction is developed with centrifugal action taking the place of hand or foot, and a type of coupling or clutch is shown with a helical clutch spring, as used in automobile clutches, taking the place of centrifugal action. The application intended is mainly for belt and pulley transmission in factories, and is meant to produce a gradual engagement. The author then proceeds to apply automatic regulation of pressures to friction drives of various sorts, indicating means for always having just as much friction between driving and driven cones as is necessary for the work in hand and to avoid slippage. Finally, the same principle is employed in connection with an expansible pulley wheel to produce automatic gear change, the pressure upon the belt acting to push the sliding half of an expansible V-pulley to one side, whereby the belt sinks to a smaller circle; that is, a lower gear. An illustration is presented of a motorcycle made on this principle by Vierordt & Co., of Kehl am Rhein, in which a tension pulley or idler operated by hand is made to increase or decrease the pressure of the belt upon one of the belt sheaves, which may be either the driving or the driven, thereby changing its radius and the gear ratio, while the tension pulley at the same time takes care of adjusting the length of the belt to the changed condition.—*D. P. J.,* April 30 and May numbers.

A statement to the effect that the "Farbenfabriken" at Elberfeld was ready to enter upon the manufacture of synthetic rubber is contradicted in *Chemiker Zeitung.* The directors of the concern confirm, however, the claim to having accomplished a successful scientific synthesis of caoutchouc at its laboratories. The stockholders and directors in their decision are said to have taken note of the fact that the scientific synthesis of indigo which was accomplished in 1880 by Prof. Fred Bayer—who is also the discoverer of the new synthetic rubber-making process—was not realized industrially until 1896, nearly 16 years later. It was also considered that a sharp decline in market prices followed the discovery of synthetic methods of production in the cases of both indigo and camphor. It would be a reduced price for rubber which the synthetic product would have to meet.—*Le Génie Civil,* June 11.

A general formula for the calculation of brake bands is given by Engineer Siebeck, and he shows how the pressures applied vary with different constructions. With brakes of automatic application, especially, the maximum pressures may become much higher than the general formula would indicate, and the author gives a supplementary formula which enables one to determine them.—*Zeitschrift des Vereines Deutscher Ingenieure,* April 16.

Automobile buses adopted by the City of Paris are of two types. One carries 30 "fares" without "imperial" or roof seats. There are eight first-class seats, while 22 places are second-class, and of these 13 are seats and nine are standing room. The other type has a capacity of 34, with 13 first-class seats and 18 second-class places. With a different division, this type has 12 first-class and 22 second-class places, and of the latter 17 are seats. —*Mém. et Trav. Ing. Civils,* May 20.

In addition to the non-inflammable new form of celluloid called cellite, which is made by treating the cellulose with acetic ether instead of nitric ether, another cellulose product appears upon the market which is also incombustible or nearly so. It is produced by means of formic acid by the Nitritfabrik Stock Company, of Koepenick near Berlin. The formiates of cellulose, besides being cheaper than the acetylates, possess the advantage of being soluble in an excess of formic acid.—*Le Génie Civil,* June 4.

Laboratory Investigation of Holley Carbureter

DOUBLE Jet Carbureters are contrived with a view to overcoming the difficulties involved in furnishing uniform mixtures to motors, it being understood that the single jet carbureter has its limitations. In the laboratory of Holley Brothers Company, Detroit, Mich., the facilities available for investigating carbureters, fuel, and motors, from the mixture point of view, are sufficiently complete to enable a physicist to arrive at excellent conclusions, and it is believed that the information here afforded is worthy of close scanning because it is presented in "dead line" form so that the interested reader is given an opportunity to obtain a bird's-eye view of the situation in general.

Referring to Fig. 1, which is a chart giving the curve of performance of the puddle type of carbureter shown in Fig. 2, it will be seen how the fuel consumption changes per horsepower, and with the speed of the motor. A summary of the results obtained is given in the tabulation under Fig. 2, and briefly stated, the gasoline consumption dropped to its lowest point as shown on the curve A B when the motor was running at 700 revolutions per minute. The highest consumption was at 1300 and 300 revolutions per minute. The line C D on the chart represents horsepower and shows how the power increased with the speed up to 1300 revolutions per minute.

The chart Fig. 3 shows the performance of the single jet carbureter, and Fig. 4 is a section of the particular carbureter used. Under Fig. 4 is a tabulation of the results obtained from which the curves were plotted. In this case, the test spread over a range from 500 to 1400 revolutions per minute inclusive, and the best gasoline consumption was at the highest speed, gradually increasing with increasing speed, reaching a maximum at 550 revolutions per minute. The horsepower developed resulting in the line C D on the chart, produced a straight line up to 1150 revolutions per minute, and an upward curve thereafter to 1270 revolutions per minutes, beyond this speed there was no increase in power. The gasoline consumption is represented by the line A B and it shows quite a few irregularities, thus bringing out the characteristics of the single jet idea in carbureter designs.

The chart Fig. 5 was plotted from data obtained in the test of the double jet carbureter; a section of this carbureter is shown in Fig. 6, and the data of the test is given in the tabulation under Fig. 6. The curve A B is of the gasoline consumption; it was maximum at 500 revolutions per minute, dropped to its lowest point at 750 revolutions per minute, but with slight variation maintained this low level beyond 600 revolutions per minute. The power obtained is represented by the straight line C D up to 1300 revolutions per minute, was horizontal from 1300 to 1400 revolutions, and took an upward sweep from 1400 revolutions to the end of the test. This chart is representative of the splendid performance of the double jet in carbureter designs, and it shows that the gasoline consumption can be maintained at substantially a constant level over the entire range of working speeds.

It is of course true that the thermal efficiency of a motor will decrease with decreasing speed if the gasoline consumption does not hold to a constant rate per horsepower. The double jet carbureter when it performs as shown in the curve Fig. 5, affords nearly a constant thermal efficiency, notwithstanding speed and power variations for almost the entire practical range of the motor. The charts give the horsepower scale in the left vertical column, the speed scale at the bottom, and the gasoline scale in the right vertical column. For any speed within the range given it is only necessary to trace along the vertical line (ordinate) of that speed to the point of intersection of the horsepower curve, and following the horizontal line (abscissa) from the point of intersection to the left for horsepower, but to the right for gasoline consumption.

THREE TYPES OF CARBURETERS TESTED AND COMPARED

Public Service Taxameters

PATRONS of taxicabs find it a rather difficult matter to ride for any length of time and feel perfectly comfortable about the pending charge. They eye the taxameter, shift about in the seat, and in every way show evidences of some strong emotion. Experience has shown that this intuition of evil is but the reflection of experience, although it is a great mistake to go on fretting about things after the evils have been eradicated and the reasons for fearing no longer exist.

With the new taxicab regulations in force in New York City, and equally good regulations in force in practically every city having taxicabs, coupled with the fact that taxameters are available within limits of error so close that there can be no question as to the fairness of the charge, if it is based upon the readings, it only remains for patrons to make themselves acquainted with the workings of the taxameter, and avoid using the chauffeur as a private secretary—allotting to him the duty of deciphering the taxameter instead of acting for themselves. If any mistake is made it is not fair to the taxicab to say that its functions are improperly performed if the trouble is confined to a mere oversight on the part of the private secretary, or if the "fare" elects to do his own reading, and, in the absence of skill, overcharges himself.

A tamper-proof taxameter is the first requisite from the point of view of good business; the operator of taxicabs cannot afford to place such an expensive piece of property in the keeping of a chauffeur and allow him to rove without having some way of keeping track of the length of his migration, even though it is not very easy to tell of the number of "pick-up" fares the chauffeur may "entertain" during the trip.

It follows, under the circumstances, that the interests of the operating company and the "fare" are identical; both parties are vitally interested in the distance that the taxicab may travel, and the only way that they can be sure of this is to employ tamper-proof taxameters.

Fig. 3—Rear View of Taxameter showing half-mile travel

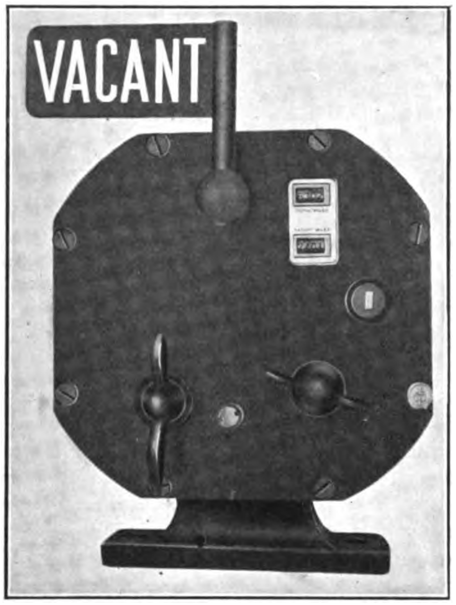

Fig. 2—Rear view of Taxameter with fare register out of service

Fig. 1—Front view of Taxameter with fare register out of service

The instrument, in view of its vital importance, should be·

(a) Automatic, (b) accurate, (c) with individual totalizers and (d) tamper-proof. That vibration and the other usages due to service will, in some measure, influence the situation, is to be expected, taking taxameters in general, but the trend is toward the character of instruments that are capable of coping with the exigencies of service with little chance of becoming deranged. This depends upon its exact construction and to the care with which it is maintained. Since it is expensive to keep up an inspection system and to make extra repairs to instruments, even not counting the inconveniences which will come if the government "inspector" fails to appreciate the good qualities of the type of instruments employed, it follows that the interests of the operating company and its patrons are on the same basis, and the best possible type of instrument is the one which will come nearest to satisfying the patron and the server.

The single fare instrument offers advantages; with it there is no opportunity for the chauffeur to juggle with the tariff.

"Fare" Should Know Taxameter

In order to afford the requisite amount of information to the patrons of taxicabs, photographs of the International Taxameter are here reproduced, which, if studied, will permit the interested reader to familiarize himself with the details of the instrument sufficiently to enable him to enjoy his ride and foot up his own tally. Fig. 1 shows the face of the instrument with the flag up, also with the fare blinds down, and the extra charge dial at zero. The initial tour totalizer, the extra totalizer, and the fractional totalizer are in full view. The aperture on the right hand side shows in bold face letters "For Hire." This sign is only in view when the flag is up.

Looking at the rear of the instrument as shown in Fig. 2 when the flag is up and the taxicab is "For Hire," the aperture shows total number of miles at the top, and dead mileage at the bottom. The latter registers only when the taxicab is vacant. Below this aperture is a spur with which the extras are registered; then comes the key to wind the clock mechanism, and in the lower corner is a little spur which is the flag locking device. At the lower left-hand corner is the flag operating key, and in the left-hand side of the base is the hole for sealing.

Fig. 3 shows the back of the taxameter when the flag is down, and Fig. 4 is of the front. The initial charge is 40 cents for the first 1-2 mile, and it shows in the right aperture below "Fare." In the "Extras" aperture there is a 20-cent charge, and in the right-hand aperture the bold-faced letters spell "Hired." The initial totalizer shows 0213, which is one number greater than before the flag dropped. The extra totalizer shows 0266, and is also one number greater than before the flag dropped. The fractional totalizer registers the same as before the flag dropped, because there were no fractions of a mile or waiting time to be registered.

Referring again to Fig. 3, the numerals of the total miles indicator show that the vehicle traveled 5-10 of a mile, and on the fractional totalizer in the lower right-hand corner on the front dial as shown in Fig. 5 there is an increase of one unit from 8465 to 8466, so that the total fare as registered on the dial of Fig. 5 is 50 cents, which is an increase of 10 cents over the fare registered in

Fig. 4—Front view of Taxameter showing fare and extra register in service

Fig. 5—Front view of Taxameter after travel of one-half mile

Fig. 6—Front view of Taxameter at instant of discharging fare

Fig. 4. In the extra aperture of Fig. 4 there is a charge of 20 cents for baggage, and this, with the fare, makes a total of 70 cents. When the passenger arrives at his destination, alights and wishes to discharge the vehicle, the driver gives one turn of the flag crank, which sets the taxameter at "Non-recording." This gives the driver time to collect his fare, but as soon as the passenger settles his account, the driver gives one more turn to the flag crank, which sets the flag in the upright position as shown in Fig. 1. The settlement must be on a basis of the amount registered in the fare aperture, plus the amount registered in the extras aperture. The total in this case, as shown in Fig. 6, being 50 and 20, equals 70 cents.

Baedekerizing the Automobile Blue Book

By HENRY MacNAIR

SO long has the name of Baedeker been associated in the public mind with guide books that from a Teuton patronymic it has come to be a substantive of general use, applying particularly to the best in the hand-book line, for a Baedeker is now deemed an indispensable adjunct to rail or boat touring.

The preface to the most recent edition of Baedeker's United States sets forth that the book is "intended to help the traveller in planning his tour and enable him the more thoroughly to enjoy and appreciate the objects of interest he meets with." To which, as a concrete expression of the mission of a guide book, the editors of the new Blue Book, with a mental reservation as to the placing of the final pronoun, most heartily subscribe, though very much, perhaps, in the spirit of the sinner who tacks the Lord's Prayer at the head of his bed, and exclaims "Lord, them's my sentiments!"

But while Baedeker undertakes to supply mental pabulum to the traveler by rail and boat, there is another constantly and rapidly increasing class which follows the highways in their own cars, often as luxuriously appointed as the most palatial railway carriage, and which heretofore has not been recognized as being in the ranks of seekers after such information. Manifestly a guide book designed for other classes will but partially supply the need of the autoist, in that it does not direct his motor to the points described. Then, too, there are other things of beauty and interest, which are as a "sealed book" to him who travels other than by motor.

It has not been thought necessary to dispute the occupation of the field pre-empted by Baedeker, for, outside, the uncultivated acres are many and expansive.

It is the avowed purpose of the Blue Book to lay before its readers not only the completest information as to all the motoring roads in a given section, but to supply in advance accurate data and reliable information as to the historic, the unusual, the quaint and the beautiful features of each and every trip. In order to attain this result, the essential road directions have been pruned of all exuberant verbosity to make room for a descriptive outline which appears in a separate paragraph at the beginning of each route. Of a surety, then, no mere plagiarization will suffice, for each "descriptive outline" must be written from actual car-observation, after consulting all the dispensers of hand-book lore and digesting the facts of local history gleaned from various sources. Indubitably no better way of sight-seeing exists than from an open motor car, the speed controlled at will, now flashing by the prosaic and unlovely, now dallying at those spots made attractive by the lavish hand of nature, or the cunning of man's art.

Then the viewpoint! It is subversive of the spirit of '76 to meekly allow a Britisher to tell us what we may see in our own country, for all of the English editions of Baedeker are edited by Dr. Muirhead; himself a worthy and erudite scholar, he is yet not free from the imputation of prejudice who dismisses our own Schuylerville and the Battlefield of Saratoga with a scant four lines in the tiniest of type. One can imagine the burst of indignation which he would bring about his ears did he give no more extended mention to the battlefield of Waterloo, and yet both are recorded among "Crecy's Fifteen Decisive Battles" of the world's history. It is, perhaps, of sufficient interest to the patriotic to reproduce the exact text of Baedeker and that of the Blue Book covering this particular point:

Baedeker—"A branch of the B. & M. Railroad runs to (12M.) Schuylerville (Hot. Schuyler $2), whence the Battlefield of Saratoga, with its monument, may be visited. Memorial tablets mark the chief points of the battleground, and there is a collection of relics in the Schuyler Mansion Museum."

Blue Book—"Leaving Saratoga on Lake Ave., a direct macadam road is followed to **Schuylerville**, a point of great historic interest, near which place the battle of Saratoga was fought. On the corner of Spring and Broad Sts. (10.9 m) a tablet indicates the camp ground of the British army (1777). To the left a short distance is the Marshall House, in the cellar of which Baroness Riedesel took refuge. To the right on Broad St. is the spot, marked by tablet, where Burgoyne surrendered, thus securing American independence. Just beyond, by turning right on Burgoyne St., we reach the Battle Monument, commemorating Burgoyne's surrender, and the close of one of the "fifteen decisive battles of the world" The monument is 154 ft. high and was completed in 1883. Among the other points of interest is the site of Ft. Hardy (1755), Fish Creek Bridge, near Schuyler Mansion, the battlefield of Saratoga and Freeman's farmhouse at Bemis Heights (22,000 soldiers engaged), and the Dovegat House near Coveville, 2 miles south."

The Blue Book, then, has a field of its own in applying an amplified Baedeker feature to its publications which, prior to 1910, only attempted to point out the road. With facts collected from all sources, and especially arranged for the convenience of the tourist, this feature will prove a boon to the sightseer.

"Senator" Callan Plays Both Ends Against the Middle

"SENATOR" ALBERT S. CALLAN, father of the New York State Motor Vehicle Law, which goes into force and effect August 1, 1910, is a confirmed bachelor. "Senator" Callan, who, by the way, is not Senator at all, but a member of the Lower House of the New York State Legislature from Columbia County, only twenty-five years old and does not look it, is authority for the statement that he is not susceptible to the wiles of Cupid.

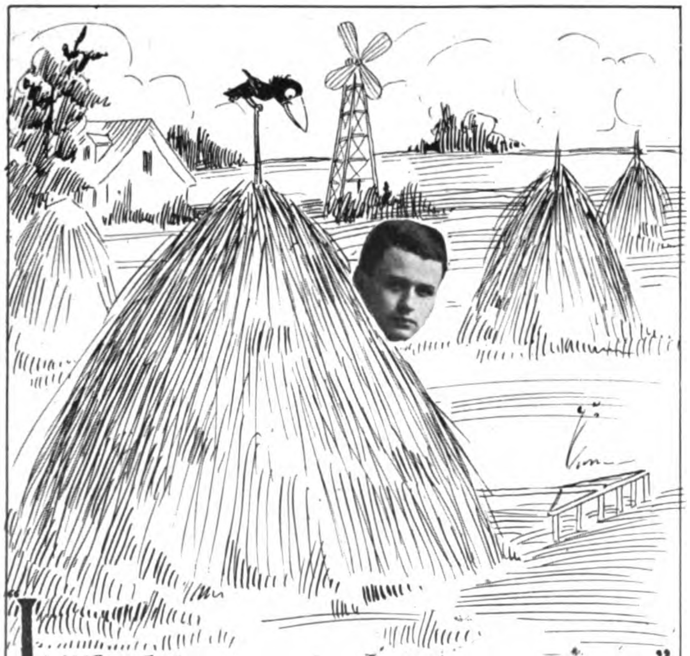
He is a charming fellow, nevertheless—a boyish, intense youth, who does not seem to realize fully that "his" law will make the official ownership of an automobile in New York State about four times as costly as it was heretofore.

In some sections of the State the automobile is not yet sufficiently popular to prove a political asset to an aspiring young legislator, and Columbia County, the constituency of the young "Senator," is said to be one of these sections. It has been whispered that opposition to motoring in the attitude of "Senator" Callan has proved acceptable to a good many of his constituents. However that may be, the legislator freely admitted to the representative of The Automobile that prior to the last campaign one of his neighbors remarked to him: "Callan, I will vote for you, and I want you to pass a law so that I can stand out in my front yard and shoot every d—d motorist that passes my place."

Mr. Callan does not take that extreme view. In fact, he does not believe that the owner and operator of an automobile ought to go to jail simply because he owns a machine, unless he breaks the law. He recognizes the fact that the importance of the automobile is growing and that really radical words or acts might have the effect of striking at some neighbor whose vote and influence at the polls would be more than a negligible factor.

But his effort at lawmaking will afford excellent chances for many a motorist to break into jail.

The man responsible for this law is a smooth-cheeked, athletic youth. He is slender and graceful in his carriage and wears his dark hair slicked back from his rather low brow. He is the possessor of an astonishing personality—this man, whose law will cost motordom $2,000,000 a year, according to the estimate of Governor Charles E. Hughes in his tentative budget figures. But let him tell his own story, just as he recounted it for the exclusive use of The Automobile:



I HAVE NEVER HAD HOLD OF A STEERING GEAR"

"I was born at Albany in 1885 and moved to Valatie, Columbia County, when I was about ten years old. I attended primary and grammar schools, and when I had received my preliminary education I matriculated at Hobart. I never was graduated from anywhere. I was a kind of special student—did not go in for the classics or even the scientific courses. I did not take a degree. As far as the sciences are concerned, I am free to admit that they never attracted me. There is so little of the love of mechanics about me that the purr of a motor car means nothing more to me than the burning of so much gasoline.

"But at college I did take an interest in athletics. I was a football and a baseball man, and was manager of the dramatic club. No, I never did anything in the line of dramatic acting. I left Hobart in 1907, having been chosen an officer in the National Guard.

"In the directory my name appears as a law student, but I have no definite idea as to when I shall be admitted to the bar. My studies along that line are far from complete. I am a politician, and my ambition is to serve the people in just as high capacity as I can reach. Some of my friends have sought to have me make the race for Lieutenant-Governor, but on account of my years that will be impossible under the law this year.

"I am a Republican, and am proud to say that I believe in the organization, first, last and all the time. I voted against the direct primary measure which was recently defeated and I am perfectly satisfied with my action.

"My political history commenced as soon as I was out of college, when I ran for the Legislature and was defeated by a plurality of 600 votes. I am a persistent man, and next year I made the race again, winning by a margin of 99. Last fall my plurality was about 1,500.

"I hope to be a member of Congress, Governor or United States Senator in time, and even in a higher office if the people call upon me to take it. The State Senator from my district is a fine man and wants to succeed himself in the Upper House. I believe he will—this time. I have heard that he does not look with enthusiasm on all the flattering publicity that I have attracted. *However, he has nothing to fear from me.*

"In each of my campaigns the automobile has been an important feature. Personally I have no use for the motor car. *I never had hold of a steering gear in my life,* although my father owns a car and I have ridden in it hundreds of time. The press has called me a 'non-motorist.'

"I have a fine little mare that I ride a great deal, and I love to walk, but the automobile and its alleged exhilaration do not appeal to me.

"The feeling against automobiles may be described under two heads—in the first place, jealousy of motorists by those who do not possess cars, and, second, hostility to motor cars by frightening horses and killing chickens. When Bill Smith buys a car and goes whizzing along the roads, cutting deep gashes in the surface and scaring Farmer Brown's team to death, the feelings of Farmer Brown for Bill Smith, and through Bill Smith for all automobilists, is potent and peppery. Just before the last election I had a talk with one of those 'Farmer Browns,' and he said: 'Mr. Callan, we know you do not like automobiles, and we want you to pass a law so that we can stand in our front gates and shoot down every d—d motorist who tries to pass.'

"I told this man that I would pass a law to check the speeding and make the motorists pay more for the privilege of cutting up the roads. This I did, and I am proud of it. Just as soon as the law had been signed by the Governor I got him to give me the pen he used, just the same as Congressmen sometimes secure the pens with which Presidents sign important bills. Then I had a little certificate drawn up, showing my authorship of the Callan Act, and I had the certificate and the pen framed. They hang in my home, and I frequently look at them with a certain element of wonder that so young a man as I should have played such an important part in legislation upon such an important subject.

"I have no regular occupation outside of politics and as an officer of the National Guard, but in the course of time I think I shall be a lawyer.

"I am a confirmed bachelor, and have no idea of marrying at present and no future intention of doing so. In fact, I am wedded already to politics."

The representative of THE AUTOMOBILE called attention to the fact that Mr. Callan's hostility to the motor car seemed to include a similar feeling toward women, business and studies, but Mr. Callan only smiled and said that in future there might be some amendments introduced.

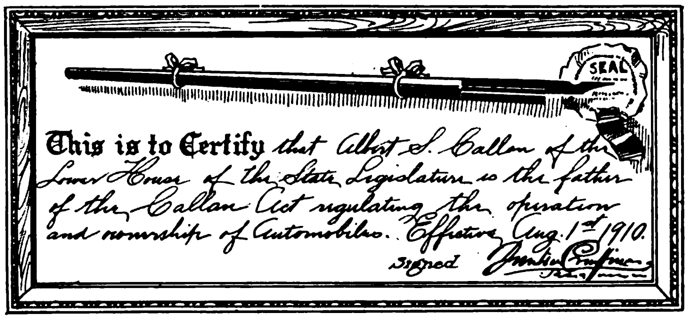
What a Lawyer Sees Amiss in the Bill

BY XENOPHON P. HUDDY, LL.B.

This law in some respects is a good one, but it also contains defects and vitiating measures which are apt to cause trouble in its practical administration, particularly referring to the great and arbitrary powers given to the Secretary of State. He is the officer designated to carry out the provisions of the act and see to it that the requirements are complied with by manufacturers, dealers, owners and chauffeurs.

It is a well-settled principle of political law that the legislative power and the duties of the Legislature cannot be delegated. It means that the Legislature of the State of New York, for example, cannot legally shift its duties to some other person or body of persons to perform since the constitutional form of government recognizes no body other than the Legislature in carrying out any form of regulatory control for the State.

Under the Callan Act chauffeurs must be licensed by the Secretary of State, but the method and details of licensing this class are not prescribed in the law itself, but the Secretary of State is empowered to prescribe an examination as to the qualifications of automobile drivers, and it is discretionary with him as to what qualifications shall be required. It is provided that no license shall be issued until the Secretary of State or his authorized agents are satisfied that the person applying for a license is a proper one to receive it. This last sentence confers immeasurable powers upon the Secretary of State and his agents in granting or refusing licenses to chauffeurs. Inasmuch as chauffeurs are depended upon to drive the greater percentage of the cars manufactured, the number of licensed chauffeurs in the State of New York may in a great measure depend upon the discretion of the official who licenses them. Instead of conferring this power upon the Secretary of State, the law itself should have prescribed the qualifications. By delegating the duty and power to the Secretary of State the Legislature has undoubtedly delegated its legislative authority, which is contrary to our fundamental law.



This is to Certify that Albert S. Callan of the Lower House of the State Legislature is the father of the Callan Act regulating the operation and ownership of Automobiles. Effective Aug. 1st 1910.

Signed

The "Senator's" Most Prized Possession—The Governor's Pen

In the attempt to place in the control of the Secretary of State the chauffeur class, and in omitting to prescribe in the law the qualifications for chauffeurs, it is very doubtful whether the law is of any validity.

For the conviction of certain offenses the Secretary of State has the power to suspend or revoke the registration of an automobile or a chauffeur's license. It is also provided that no new license shall be granted where one has been suspended or revoked, unless the discretion of the Secretary of State so authorizes it. Here again we have the discretion of the Secretary of State controlling to a certain extent the automobile industry in the State of New York. Arbitrary action on his part is possible and can work great damage, but a person who has been arbitrarily treated could bring a writ of mandamus to make the Secretary of State grant him the privilege to use his automobile on the public ways of the State.

It has been announced in the press that the Secretary of State will not issue licenses to drivers of known recklessness. The elimination of drivers of this character should be accomplished, but the discretion of the Secretary of State alone should not constitute the sole judge of whether a citizen is a reckless automobile operator. The fact that chauffeurs are compelled to state in their application blanks, under oath, whether they have been convicted of violating any automobile law is in itself a vitiating requirement. Whether a chauffeur has, or has not, been convicted of violating any automobile regulation in the past has nothing to do with obtaining a license under the new act.

The administration of this law necessarily demands quite a large force of persons as examiners. These examiners have been appointed. It cannot be denied that the patronage is large which has been placed at the disposal of the Secretary of State and for this reason alone the law should have prescribed, not only the qualifications of chauffeurs and drivers, but of examiners.

The law does not require any examination of an owner of an automobile who drives his own car. Only chauffeurs must be licensed. Sons and daughters may drive their fathers' cars without obtaining a license, provided they are 18 years of age. Any non-owner may borrow a car and drive it without a license.

In regard to the fees charged, the graduated fees according to horsepower are in lieu of all taxation. This provision is unconstitutional since it amounts to a special exemption of motor vehicles from taxation while other vehicles used on the public highways are subjected to being taxed.

ENGLAND:—W. H. Smith & Sons, Ltd., 186 Strand, London, W. C., and all bookstalls and agencies in Great Britain; also in Paris at 248 Rue de Rivoli.
FRANCE:—L. Baudry de Saunier, offices of "Omnia," 20 Rue Duret, Avenue de la Grande Armee, Paris.
GERMANY:—A. Seydel, Mohrenstrasse 9, Berlin.

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

THE news value of the automobile industry is sufficient without drawing upon the views of Wall street. The reasons why money is being locked up in the vaults of savings banks will have to be explained on some basis which does not impugn the economic stability of the automobile industry. The Chicago *Inter Ocean* of July 7, in quoting extracts from an editorial which appeared in THE AUTOMOBILE, concludes by shedding light which clinches the contention that small investors have good reasons up their sleeves for not risking their hard-earned cash in Wall street. When the champions of "high finance" show as clean a pair of heels to dishonesty as the automobile is able to present, they may then be in a position to finger hard-earned money, the lack of which the automobile industry has never felt. The arguments presented in the *Inter Ocean* were as follows:

> The automobile industry is indignant over the effort of Joseph T. Talbert, vice-president of the National City Bank of New York, to blame our present financial worries upon the large outlay which the people of the United States are making in automobiles. Mr. Talbert, in a speech before the Texas Bankers' Association some time ago, declared that this "economic waste" approximates $500,000,000 a year—one-half for new machines and one-half for the maintenance of those in use.
>
> The automobilists have taken issue with Mr. Talbert by demonstrating that the larger part of this outlay is for machines used for business purposes and that the actual expenditure for pleasure automobiles for 1910 will be just about $104,000,00, to which must be added the cost of maintenance.
>
> Moreover, the automobilists point out that the expenditure of even this sum for pleasure automobiles is merely taking the place of other kinds of pleasure payments. If it were not the automobile, it would be something else that would cost money, whether it be horses and carriages, or going to the theatre, or books.
>
> But why worry over these figures or over the other possibilities for the purchase of luxuries? Mr. Talbert's attempt to unload our financial anxieties upon the automobile will never explain the worries of our financiers. It will not explain why the small investors are locking their money up in savings accounts instead of using it in the purchase of stocks and bonds, or why the railroads are curtailing expenses and improvements.
>
> A dozen years or so ago half of America—masculine and feminine alike—was astride of bicycles, but the investment in that luxury did not cause the pillars of the stock exchange to tremble. In a dozen years from now we may all be drawing on our savings bank accounts to buy airships, but the fact of itself will have no more bearing on the status of the financial world than a matinée girl's extravagant investments in chewing gum and ice cream.
>
> The financial worry which is giving our New York bankers some uneasy nights has far more important causes than the purchase and use of automobiles. And if Mr. Talbert spoke his full mind he would admit it.

* * *

MOTOR trouble, due to the accumulation of carbon in the combustion chambers and over the piston heads, is looked upon by the average autoist as a regular thing. Every time a motor shows a tendency to overheat, or when a back kick is too readily realized, the autoist runs for his can of carbon remover and makes haste to dump it into the motor's cylinders. The right time to apply a remedy is when the disease is such as to demand it. Physicians claim that a patient's system is fortified against poisonous nostrums only when the nostrums are indicated and the patient is really suffering from the malady that demands them. Take mercury, for instance; but a slight amount of this poisonous substance will prove fatal to a well man, whereas when this medicine is indicated the amount of it that the patient is able to absorb with impunity is remarkable. In the same way, carbon remover in a combustion chamber will be absorbed with impunity if there is carbon present, but if a cylinder is in good health, then the carbon remover as a medicine will be free to attack the cylinder, instead of doing useful work.

* * *

FREQUENTLY when a diagnosis of cylinder trouble is being made, the conclusion is on a snapshot basis. Instead of incrustation within the cylinder walls being at the bottom of heating troubles, it will more likely be found that the accumulation is over the exterior surfaces of the dome. Such formations produce spheroidal action in the water. No matter how vigorous the water circulation is, there will be no transfer of heat worth taking into account after the temperature rises beyond a certain point, as it will when the conductivity of the dome is stilled by incrustation, so that spheroidal action is what takes place and cooling action dies. When a motor is being examined, a diagnosis of the malady to be complete must include an examination of the exterior dome surfaces as well as the internal walls of the cylinders.

* * *

COOLING, if it is regarded as a necessary evil, is seen in the right light, but the reasons for cooling are rarely ever properly considered. Every heat unit "sponged" off of the cylinder walls by the circulating water is a dead loss. Any plan which makes it unnecessary to rob the cylinder of its heat is a clear gain. When we consider that substantially 50 per cent. of every gallon of gasoline put into the tank leaks out of the radiator in the form of heat, we have a basis for pondering that should convey its own reward.

EFFICIENT cooling is only to be realized when the heat escape from the combustion chamber is retarded to the greatest possible extent, to do which demands that the "gate" be restricted. Since all the heat must go through the cylinder walls to get to the cooling water, it follows that limiting area of surface puts a stop on the heat transfer. This limitation, to be efficacious, must be applied in conjunction with the flame-swept surfaces; in other words, it is the inner wall which must be limited in area.

* * *

WHEN the transfer of heat is snubbed to the greatest possible extent by reducing the flame-swept surface to the minimum, the remaining problem is to maintain the cylinder walls at a working temperature. This is done by directing a sheet of water over the exterior surfaces and counting upon the same to absorb heat from the material of the cylinder walls at a rate which will prevent the material of which they are made from increasing in temperature above the safe working temperature of the lubricating oil used within the cylinders. When this task is performed, any further cooling effort detracts from the thermal efficiency of the motor.

* * *

PREPARATIONS for a war with Japan are now going on in this country. The training camps in the several States are filled with militia which is being trained by Federal officers, perhaps for the purpose of whipping it into shape in time to say "How-do-you-do" to the little brown man when he comes. The chances are that the Panama Canal will be a blind ditch when war drums beat. Japan probably knows that the only chance it will ever have will be before the completion of the water connection referred to. In the meantime, the public must look on and assume an attitude of stolid indifference, while the resources of the country are being dissipated to some extent, at any rate, in the training of men who may elect not to respond to the call when it comes, all of which, to the high disregard of the progress which has been made in aeronautical work.

* * *

BATTLESHIPS are limited in their radius of action to the distance that a shell may be projected from the mouth of the most powerful guns employed, after the ships reach an enemy's shores. Aeroplanes do not have to be protected from the gun play of the enemy's battleships, nor are they limited in their radius of travel by shore lines. The only object in going to war is to make the enemy pay a war indemnity. A half-dozen well-directed shells dropped from a perch in the clouds would bring money out of a miser's coffers, let alone the treasure box of a community.

* * *

ADMITTING that the deliberations of the Supreme Court are bound down by precedent, even taking it for granted that they should be, the fact remains that the General Staff is in poor business looking to precedent as a safe guide and a proper rule. The little brown man, when he comes, will pay high disregard to the precedents and rulings of the Supreme Court. If he brings with him a pack of aeroplanes, and the kind of men who are accustomed to staring death in the face with a bland smile, the little brown men will have fun with the militia, and the General Staff will then have to do but poorly and in a hurry the things it may now accomplish efficiently with ample time.

* * *

ABROAD an international touring law is being fashioned, which will permit of touring all over Great Britain and the Continent with no greater inconvenience than the autoist will encounter on a trip from London to Coventry. In New York State a law is about to be put into force which puts it up to the autoist to decide whether he will get rid of his automobile or the lawmaker who is responsible for his trouble. If the Callan Bill is a good one, every autoist in the Empire State should exert his influence for, work for, and vote for the "Senator" who says he is responsible for the bill; but should the bill prove to be a crown of thorns, it should be remembered that the "Senator" professes to be serving a certain class of citizens who have never been over friendly to the automobile.

* * *

PUBLIC service, from the cab point of view, has always had its sore spot, due to the fact that patrons unfamiliar with city streets were compelled to rely upon the word of the jehu for the distance traversed. The occupant of the driver's seat, with an eye to business, always seems to have seen double when it came to the settlement of the account based upon the miles traveled, and when taxameters came into vogue, the "fares" drew a long breath. There were yet a few details to be mastered; with the coming of the mechanical tell-tale came the driver with a mechanical bent, who manipulated the machine, and, frequently, offset the advantage that was to be derived from it. The time has arrived in the advance of the art when the "fare" is no longer concerned about the crooked wiles of the jehu. Taxameters are tamper-proof, and public inspection should debar them from traveling faster than the cab.

* * *

TOURING time is here and the autoist with his car is to be seen wherever the roads are fit to be traveled upon. But a change is coming over the personality of the autoist who tours on pleasure bent; it is no longer a question of how fast will the automobile go, or how far is it from one place to another, as much as it is a question of where the tour leads, and what of interest will be encountered along the way. This phase of touring is handled by the Automobile Blue Book as a Baedeker feature. Points of historic interest are sufficiently described to permit the autoist to decide as to the expediency of including them in the itinerary of the tour. In the old way of mapping out a tour, it sometimes happened that the autoist traveled a thousand miles to inspect some historic scene that he happened to know about, passing possibly a dozen of more interesting spots along the wayside, because he did not know about them. It is possible to profitably spend a week on a single route within a hundred miles from home, and the cost is enormously reduced. This Baedeker feature is the best remedy for a large tire bill that has ever been devised.

Official Program for the Convention for S. A. E.

HOTEL TULLER, DETROIT, MICH., JULY 28, 29 AND 30

THURSDAY

9 a.m.—Business Session.

2 p.m.—Professional Session.

7 p.m.—Society Dinner and Professional Session.

FRIDAY

9 a.m.—Visit to Manufacturing Plants.

1 p.m.—Boat Trip and Discussion of Papers.

Evening—Dinner at Light House Inn.

SATURDAY

9 a.m.—Professional Session—Commercial Vehicles.

1 p.m.—Professional Session.

THURSDAY, 9 A. M.—BUSINESS SESSION

1. Opening Address by the President: "The Future Aims of the Society and the Work Already in Hand." H. E. Coffin.
2. Report of Tellers of Election of Members.
3. Treasurer's Report.
4. Reports of Committees.

Subjects for General Discussion

1. The Society of Automobile Engineers, the Lines Along which the Organization May be Made of the Greatest Value to its Members Individually and to the Motor Car Industry.
2. The Society Constitution and its Limitations.
3. Suggested Amendments to the Constitution which May Facilitate the Practical Work of the Society.
4. The Publication of a Digest of Technical Literature.
5. The Conduct of a Reference Library.

THURSDAY, 2 P. M.—PROFESSIONAL SESSION

1. The Specification and Heat Treatment of Automobile Materials. Address by Mr. Henry Souther.
2. The Test of a 20 H. P. Franklin Air-Cooled Motor. By Prof. R. C. Carpenter.
3. Variation of Current Practice in Anti-Friction Bearings. Paper by D. F. Graham.
4. The Pyrometer—Its Development and Use. Paper by W. H. Bristol.
5. Testing the Hardness of Metals. A. F. Shore and H. G. McComb.

Subjects for General Discussion

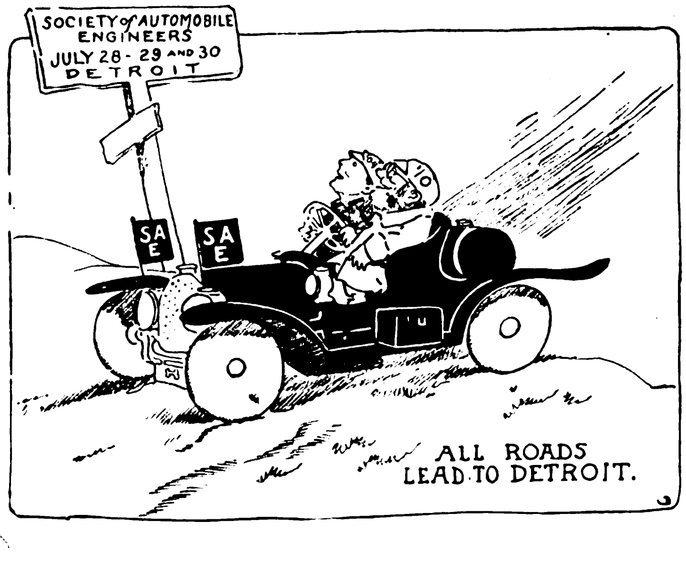
1. The Engineering Lessons to be Learned from the Motor Car Contest.
2. Drive Shaft versus Rear Wheel Brakes.
3. Three-Point versus Four-Point Suspension.

THURSDAY, 7 P. M.—SOCIETY DINNER

followed by

Professional Session

1. Report of Committee on Tire Efficiency. By F. J. Newman, Chairman.
2. Report of Committee on Gear Steels. Dr. G. W. Sargent, Chairman.
3. The Basis for Motor Car Taxation. Charles Thaddeus Terry, Legal Adviser of the American Automobile Association.
4. The Establishment of a Court of Patent Appeals. By E. J. Stoddard.
5. How to Make Gears Quiet by Grinding. Frederick A. Ward.



Subject for General Discussion

1. The Responsibility of the Motor Car Engineer to His Company and to the Public.

FRIDAY, 9 A. M.—VISITS TO MANUFACTURING PLANTS

Aluminum Castings Company,
Burroughs Adding Machine Company,
Cadillac Motor Car Company,
Chalmers Motor Company,
Detroit Steel Products Company,
E-M-F Co.,
Gear Grinding Machine Company,
Packard Motor Car Company,
Timken-Detroit Axle Company.

(Members to elect three of above plants which they individually wish to visit; visiting parties to be grouped accordingly.)

FRIDAY, 1 P. M.

Members will meet at the offices of the Timken-Detroit Axle Company for luncheon on shipboard and for an afternoon boat trip as the guests of the Timken-Detroit Axle Company.

Professional Session on Shipboard

1. Seamless Steel Tubes and the Necessity for Standardization in Their Specifications. By H. S. White.
2. Slide, Rotary and Piston Valves versus Poppet Valves for Gas Engine Service. Paper by Eugene P. Batzell.
3. Ill-Smelling and Smoky Exhausts. Paper by F. D. Howe.

Subjects for General Discussion

1. Wheel Alignments; Camber and Foregather.
2. Hot Rolled Gears (Teeth Rolled in) for Transmission and Differential Purposes.
3. Best Tooth Form for Quiet Gears, Both Spur and Bevel.
4. Valve Seat Angles.

FRIDAY EVENING

Social Session. Dinner at Light House Inn for those attending convention and for the ladies accompanying them.

SATURDAY, 9 A. M.—PROFESSIONAL SESSION
COMMERCIAL VEHICLES

1. Motor Trucks for Railroad Service. Paper by T. V. Buckwalter.
2. Test Data Upon Sheet Metal Frame Sections. By L. R. Smith.

Subjects for General Discussion

1. Proper Power and Speed for Gasoline Motors for Truck Purposes, and Proper Road Speeds for Vehicles of Different Capacities.
2. Location of Motor for Commercial Vehicle Work—in Front Under Bonnet or Under Seat.
3. Long Stroke versus Short Stroke Motor—Advantages and Disadvantages of Each.
4. Driver's Seat on Left versus Driver's Seat on Right for Commercial Car Purposes.
5. The Edison Battery in Practical Vehicle Service.
6. Electric Vehicle Mileage.
7. Fool-proofing the Commercial Car Mechanism and Its Control.
8. Standardization Possibilities Within the Commercial Car Field.

9. A Proper Nomenclature in the Distinction of Freight and Passenger Vehicles.

10. Tire Mileage and Costs.

SATURDAY, 1 P. M.—PROFESSIONAL SESSION.

1. Nomenclature of Motor Car Parts. Paper by F. E. Watts.

Subjects for General Discussion

1. Driver's Seat on Left versus Driver's Seat on Right for Pleasure Car Purposes.

2. Leaf Springs, Methods of Mounting and the Treatment of Springs by the Manufacturer and in the Hands of the Motor Car Owner.

3. Magneto Efficiency.

4. Current Practices in Lubrication and the Practical Results Obtained.

5. Standardization Problems. Those Matters which Deserve the United Attention of the Motor Car Engineers in an Effort to Simplify the Purchasing Department and Deliveries Problem.

Papers

1. Cork Insert Pulleys as Applied to Motor Vehicle Manufacturing Machinery. Lawrence Whitcomb.

2. Carrying Appliances for Tools, Tires, etc. By H. H. Brown.

ADDITIONAL SUBJECTS

For Discussion if the Opportunity Affords

1. Single versus Dual versus En Bloc Cylinder Constructions—the Advantages and Disadvantages of Each.

2. Two versus Three versus Five Bearing Crank Shaft Construction.

3. Die Cast versus Sand Blast Bearings.

4. T Head versus L Head versus Valve in Head Cylinder Construction.

5. Cast Iron Valves.

6. Piston Ring Fitting and Piston Ring Friction.

7. Proper Portioning of Cooling Systems.

8. Foreign Matter in Commercial Gasoline Obtainable Upon the Market at the Present Time.

9. Motor Noises and Their Remedy.

10. Brake Materials.

11. Influence of Case Form and Bearing Style Upon Gear and Gear Box Noises.

12. Six Cylinder versus Four Cylinder Motors of Equal Rating.

13. Practical Experience with Fixed Ignition Timing.

14. Single versus Multiple Ignition Points.

15. The Gear Ratios of Three and Four Speed Transmissions.

16. The Relation of Transmission and Rear Axle Noises.

17. The Preparation of a Stock Car for Racing Work.

18. Worm Drive.

19. Motor Power Required to Drive a Motor Car on Various Road Surfaces at Various Speeds.

All automobile engineers are invited to attend the convention, whether members of the Society or not.

British Supplies Manufacturers to Organize

Patterned after the A. L. A. M., the British manufacturers of automobile and automobile accessories and supplies is in process of formation. In addition to the makers, the organization will include agents and the main purpose of the body will be to prevent concessions from the list prices of the trade.

During the past two years, the tendency of fierce competition has been to force agents to divide commissions in order to get business and as a result, the selling end of the game has acquired an unhealthful tinge.

Already a number of the most important makers located in the Birmingham district have joined. Representatives of foreign automobile makers have been invited to take part in the new organization.

The Automobile Becoming Popular in Jamaica

Consular reports from Jamaica show that the use of the automobile in that tropical land is increasing sharply. Consul Frederick Van Dyne, stationed at Kingston, says that while last year the number of motor cars owned in the city was six but that now there are over 25, besides those used by the Jamaica Motor Company, which operates a passenger, mail and freight line. There are 2,000 miles of excellent roads in Jamaica, and according to the consul, a car that can climb hills will find its use in that delightful island.

Midsummer "Regal Plugger" Is Out

Full to the covers of interesting matter, the midsummer number of the *Regal Plugger* has made its appearance. The neat little booklet, edited by Norman I. Taylor, contains several technical reviews, touring stories of a descriptive nature and a mass of miscellaneous reading all aimed to interest readers in the automobile line.

Kaaterskill Clove Climb Postponed

Owing to scarcity of material available at this time, the reliability run and hill climb that was being promoted by the Motor Contest Association to take place July 16-18 from New York to Catskill, with the climb up Kaaterskill Clove, has been postponed until September 10-12.

Flanders "20" Under Mexican Flag

With two-thirds of its big tour from Quebec to Mexico City accomplished, the Flanders "20" car now en route is steadily plugging southward through the Mexican republic. So far the trip has proved eventful in that road conditions in Canada and in the Ozark section of Missouri were unprecedentedly bad. But those who ought to be in position to know declare that the Three Flags car has only started on its real trial. The Mexican roads are in a class by themselves.

"When they are good they are very, very good, and when they are bad they really deserve very little mention." At least that is the sentiment of several of those who have essayed the trip from Laredo to the capital.

There are numerous bandits of a peculiarly insistent character in the northern part of the country and while it is always pleasant, high on the central plateau if one can reconcile himself to a diet of frijoles and tortillas, superheated with a small red pepper that makes a Harlem gas stove seem like a January morning in Winnipeg.

The crew has expressed itself as "being game for the frijoles," and at latest advices the Flanders is down south of Monterey, working along toward the National road.

Regal Company Establishes Branches

For the last six months the Regal Motor Car Company has been engaged in the establishment of branch houses. For over two years the Regal Company has owned and operated a branch house in Detroit, and it was decided to open direct factory branches in the largest distributing centers in the United States and Canada.

The branches that have already been established are located in Detroit, Buffalo, Boston, New York, Philadelphia, Kansas City, Wichita, Oklahoma City, Chicago, Denver, Minneapolis, Indianapolis, San Francisco, Toledo, Lincoln, Neb., and Toronto, Ont.

New Club Formed at Macon, Ga.

MACON, GA., July 11—The Macon Automobile Association has been organized with the following officers: F. B. West, president; S. R. Jaques, Jr., vice-president: J. C. Wheeler, secretary, and L. O. Stevens, treasurer.

Detroit Prepares to Give Elks Notable Time

DETROIT, MICH., July 11—It is going to be a great week in Detroit; great for the Elks, who will be here 100,000 strong, counting wives and sweethearts, and great for the motor car interests of the city, for at no gathering since the auto came into vogue has it been such an important contributing factor as it will be in the 1910 reunion of the country's antlered tribe. The selling of cars this week will be a secondary consideration, except as the cars may sell themselves, so to speak, for the dealers, in common with Detroit citizens generally, will be too busy showing the visiting Elks a good time to think of business to any great extent, but they will reap their reward later on. The auto parade scheduled for Friday will likely prove an eye-opener to the visitors, and if they do not go back to their homes convinced that Detroit is the hub of the universe as far as the manufacture of motor cars is concerned, it will not be the fault of the local makers.

Robert K. Davis, of the Maxwell-Briscoe Detroit agency, is chairman of the auto committee, and he has been working for weeks on the details of the parade in the hope of making as fine a showing as possible. At first he figured on about 2000 cars, but the present outlook is that there will be nearly 3000 in line. As arranged, the parade will be about 20 miles long and will easily outdo anything of the kind ever attempted before. For Mr. Davis' use during the convention the Maxwell-Briscoe folks have provided a Maxwell roadster finished in white and purple, the Elks' colors. It made its first appearance on the streets yesterday and attracted much attention.

Conspicuous in the parade will be the Buick flyers which gave such a good account of themselves in the Indianapolis speedway races. Team Manager Wadsworth Warren arrived in the city last Tuesday with his crew, including the Chevrolet brothers and Burman.

The visiting Elks may have an opportunity to see just what the speed marvels can do before the week is over. Plans are under way for a series of exhibition matches at the Grosse Pointe race track, as an added feature of the week's program. In this event some lively brushes may be looked for. The entire complement of machines used at Indianapolis will be on exhibition here during the week and in the parade, including the Buick Special "60," the Buick Model 10, the Marquette-Buick 10 A and the Marquette-Buick 16-b.

The extensive grounds of the Detroit Athletic Club on Woodward avenue have been taken over entire by the General Motors Company, and a whole city of tents has been erected to take care of cars manufactured in General Motors plants and owned by visiting Elks. No charge will be made for this accommodation, and there is ample room.

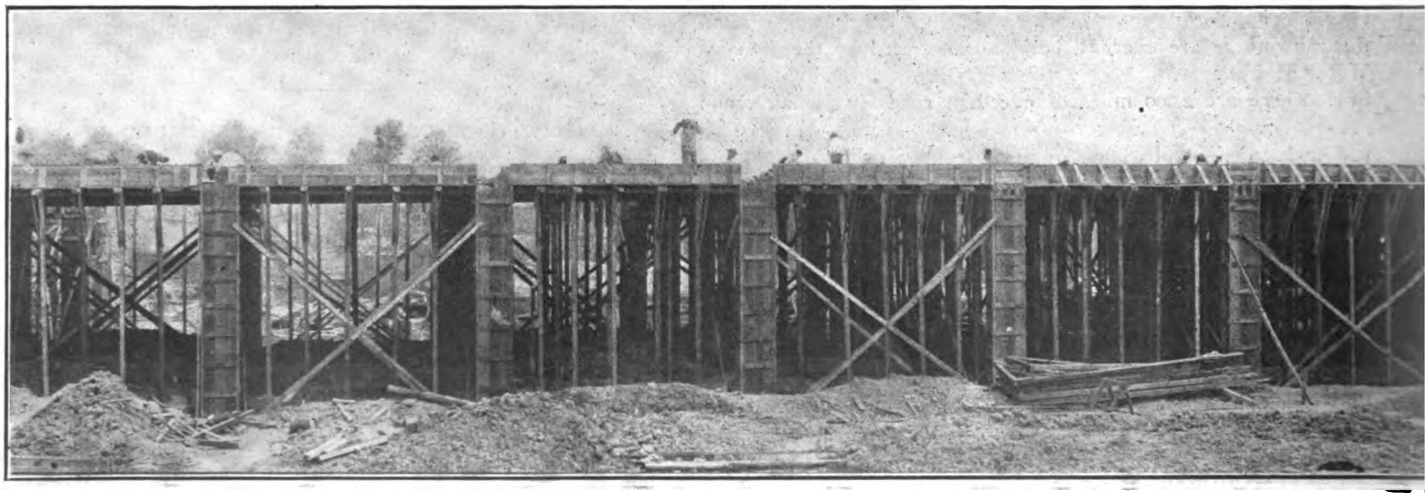
The Grabowsky Power Wagon Company has tendered the Elks the use of a special Palace sight-seeing car during the reunion, together with the services of a competent driver. The car was given a try-out last week with a party of prominent local Elks along as guests of the Grabowsky company, and it proved a big success. The car is finished in deep purple with white running gear.

For the relief work of the ambulance corps that will be on duty during the convention the Hudson Motor Car Company has tendered 12 machines and will supply more if they are needed, it is announced. A Hudson touring car has been donated as the first prize to the ladies making the finest showing in the grand parade next Thursday. It will be up to the ladies to decide which of their number shall have the use of the car.

The Brush car is getting its full share of publicity out of the reunion. The Abernathy "kids," Louis and Temple, aged 6 and 9 years, respectively, who rode 2,000 miles across the continent on horseback to greet Col. Roosevelt on his return trip, are headed this way in a Brush runabout purchased for them by their father in New York. They are due to arrive here Wednesday night and will be one of the big features in the auto parade Friday. A Maxwell car is acting as pathfinder on the trip from New York. A big dinner has been arranged for the "kids" on their arrival and Mayor Breitmeyer will extend a formal welcome.

W. K. Hadley, manager of the United States Motor Company's branch in Albany, N. Y., reached here yesterday afternoon after a 1,000-mile drive from Hartford, Conn., in a Columbia four-passenger roadster. The first leg of 135 miles to Albany was made in five hours flat. The roadster is the official car of the Albany lodge of Elks, and Mr. Hadley carried letters from the Albany lodge to the Grand Exalted Ruler of the order and from Gov. Hughes and the Mayor of Albany to Mayor Breitmeyer. Two punctures were the only mishaps on the trip. The actual running time was a trifle less than 33 hours.

Such is the demand for space in the new auto building at the State fair that it has been necessary to draw lots for it. The drawing took place in the Griswold House Friday evening and the Michigan Motor Sales Company secured the choicest position. The other firms in the order of the drawing are as follows: Cadillac Motor Sales Company, Overland Motor Car Com-



The giant factory plant of the Hudson Motor Car Company at Detroit is rapidly taking shape. The main building, which, when completed, will be one of the model automobile manufacturing plants in the country, is now well above ground and its outlines in reinforced concrete give a good idea of the immensity of the structure. The building as projected will cost in the neighborhood of $500,000 and at the present rate of construction, it will be finished this summer. The building, which is the last word in structural method, will be compact and economical of space, despite its vast size. In addition to the merely utilitarian factors of scientific pany, W. F. V. Neuman, Keeler-Hupp Company, Detroit Motor Sales Company, J. P. Schneider, Brush Motor Car Company, Buick Motor Company, Van Dyke Auto Company, J. H. Brady Auto Company, Grant Bros., Rapid Motor Vehicle Company, Maxwell-Briscoe Auto Company, Harper-Aldrich Auto Company, Cartercar Company, Winton Motor Carriage Company, Regal Motor Company, Olds Motor Company, Security Auto Company, Lyon Motor Sales Company, Anderson Carriage Company, O. B. Fear, Montgomery Motor Sales Company, Ford Motor Company, Empire Tire Company, Atlantic Repair Company, Grace Motor Products Company, Emil-Grossman Company, Auto Equipment Company, Standard Oil Company and the Vesta Accumulator Company.

The answer of the Carhartt Automobile Corporation in the suit of the Columbia Motor Car Company and George B. Selden was filed in the circuit court last week by Henry C. Walters, the attorney of the independent manufacturers' organization. It differs from most of the others filed in that the company claims to have had a definite promise of a license as soon as any more are to be issued. Several new licenses have been issued since, but none to the Carhartt corporation. The answer also sets up that no cars had been manufactured at the time the suit was filed.

Sales Manager Craven, of the Sibley Motor Car Company, brought out the first new Sibley "20" 1911 model which will leave the factory Friday. The car has a 100-inch wheel base, 32-inch wheels, a roomy body with long hood, metal shroud around the dash and an oval gasoline tank in the rear. The steering wheel is laid well back. The Renault type of motor is used and the cylinders are cast in pairs. The engine is cooled by the thermosyphon system and the Bosch ignition is used. The clutch is of the internal cone type; sliding transmission, with the three speeds ahead and reverse. The motor, clutch and transmission are in one unit with one central support in front and at each side of the clutch. The company will begin active operations in its new factory in the west end about July 18.

Collins & Company, distributors of Marmon cars, have moved into their new quarters at No. 1235 Woodward avenue, and will hold open house all week. The Stewart Speedometer Company will be established in its new home in the North Woodward section in a few days.

Martin D. Pulcher, purchasing agent and secretary of the Oakland Motor Car Company since its organization three years ago, has resigned to become general manager of the Bailey Motor Truck Company, in Detroit.

Two new factories closely identified with the motor industry have recently started operation in Detroit. They are the Murphy-Potter Company, manufacturing brass castings, and the Smith-Matthews Foundry Company, iron and semi-steel castings.

The Brush-Chicago Motor Company, of Detroit, has increased its capital stock from $11,000 to $12,000.

Carl H. Page, of New York, has been in the city for several days arranging for the first allotment of 1911 Chalmers cars. He is accompanied by Sales Manager Montgomery. Other Chalmers dealers in town are: H. H. Peters, Minneapolis, and J. H. Valentine, of the Amos Pierce Auto Company, of Syracuse.

Nashville Wants Twenty-mile Speedway

NASHVILLE, July 11—A 20-mile auto speedway, estimated to cost about $100,000, is a probability for Nashville, as the Nashville Automobile Club has launched a movement looking to that end. The matter is to be taken up for final action at the next membership meeting of the club and if it appears that there is enough interest in the matter, a large and representative committee will be appointed and the project pushed through.

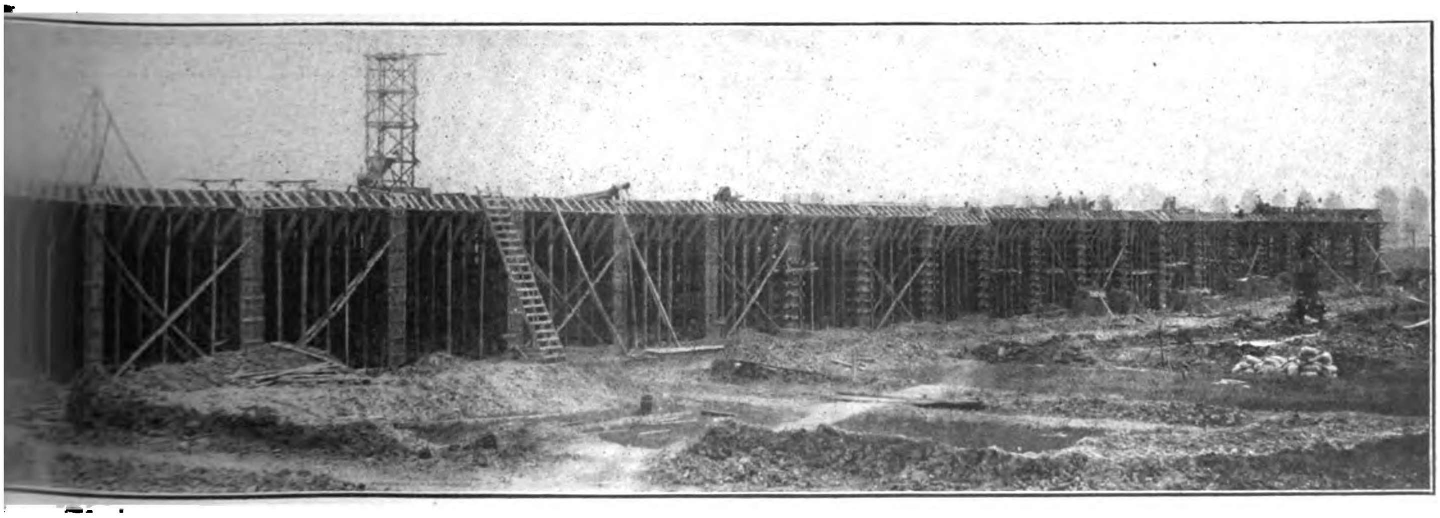
Secretary C. C. Gilbert says his idea of the route is to start in the extreme Western suburbs of the city, pass Bosley Springs, a noted picknicking place, and come in the Harding road and Broadway, the swell pike and street of the city; cross over several other pikes around the southwestern suburbs and pass by Glendale and Cumberland Park, a distance of about twenty miles. It is proposed to have the speedway 100 feet wide, with a 40-foot driveway on each side and a 20-foot parkway in the middle. This would really give forty miles through the prettiest section surrounding the city.

One suggestion is that the driveway be paved with processed wooden blocks, and if this is done it will be one of the best in the country.

A club house is part of the plan. This would be near Bosley Springs. This could be made to cost any amount that suited the members. The cost of the road is estimated at $5,000 per mile. It is not believed the right of way would cost anything, as it is understood this would be donated. Mr. Gilbert's idea is to have the county issue bonds for the speedway. If the plan goes through it is proposed later to extend it to cross the Cumberland river, which runs through the center of the city, and go out several miles to the National Cemetery, where several thousand Union soldiers are buried. It is believed the U. S. Government could be induced to build a portion of the road leading to the cemetery, that is, to widen and improve the present road.

The whole matter will come up at the next meeting of the Automobile Club.

It is probable that all pikes leading out of Nashville will be oiled for a distance of three to five miles from the city limits and that the streets leading into the city from the pikes will also be oiled.



arrangement, the building will contain numerous sanitary features of high excellence, including plenty of light for the operatives, the highest type of plumbing and bathing arrangements, besides other factors that make for more comfort for the employees.

The accompanying picture shows enough of the structural work to give an idea of the size of the main building. The concrete pillars are clearly outlined in the illustration and as they form the basis of the structure, the picture has a certain degree of significance for all those interested in the building of similar plants.

The Munsey Historic Tour Interests Patriots

AFTER an interesting trip of three weeks, the pathfinding party of the Munsey Historic Tour completed its labors last week, having mapped out a course of 1650 miles for the run that is scheduled to start from Philadelphia August 15.

The route roughly is across New Jersey to West Point, from thence to Massachusetts, trending southward as far as New London, Conn. Boston is the eastern limit of the tour, where the cars will swing backward, crossing New Hampshire and Vermont, entering New York State at Lake Champlain. A day will be spent amid the scenes of early military achievements of the American colonists and the battlegrounds of the Revolutionary War adjacent to Lake Champlain, and then the westward course will again be resumed to Binghamton. A circle through Wilkes-Barre and thence to Washington will complete the run, which is intended to be the feature of the year from a touring viewpoint.

The entry list will undoubtedly be large and representative, and already a big list is assured. The tour itself will require ten days and will combine in an extraordinary degree the business features of testing the cars and the pleasure of touring amid scenes of intense interest to patriots and scenery that is unexcelled on this side of the Cascade Mountains.

Items of Interest from Quaker City

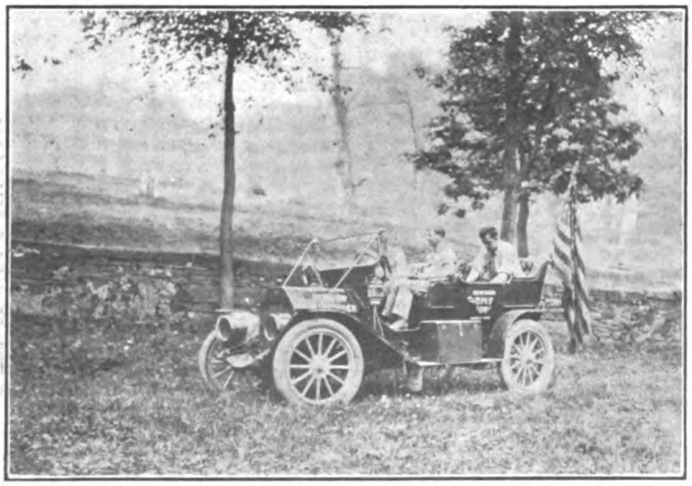
PHILADELPHIA, July 11—Announcement was made to-day by the Quaker City Motor Club that it will on Saturday, August 6, conduct a six-hour endurance contest at the Point Breeze track. The event will be open to stripped cars of Class C, Divisions 1 to 6 inclusive, for which the entrance fee will be $100. Two prizes will be awarded, the winning car to receive $750 and the second car $250.

William C. Longstreth, head of the Longstreth Motor Car Company, Philadelphia agents for the Alco and Pullman cars, sailed for Europe on Tuesday and is expected to be abroad for several weeks.

Announcement was made Saturday that the B. C. K. Motor Car Company, of Philadelphia, local representatives of the Kline-Kar, had been purchased by W. D. Shepherd and T. W. Pritchard, comprising the Krit Sales Company, 203-205 North Broad street, and that that company will be the distributing agency for both the Kline-Kar and the Krit.

Aroused to action by the tremendous success of the North Wildwood Automobile Club's Independence Day meet, other Jersey coast resorts are commencing to realize the advantages to be derived from holding automobile races. Nothing so attracts and enthuses the crowds that flock from the big cities as a series of races capably managed. The latest of the watering places to fall in line is Ocean City. A motor club was recently organized and held its initial run last Saturday to Cape May. Encouraged by the success attending the first effort, arrangements are now being made for an automobile race to take place shortly.

Clarence E. Purdy, formerly connected with the Bergdoll Motor Car Company, has been appointed superintendent of the Chalmers-Hipple Motor Car Company, 206 North Broad street, Philadelphia.



The Munseyites Stop at the Nicholas, Pa., Estate of Galusha Grow, Speaker of the House During War Times

Fourteen Enter Buffalo Tour to Date

BUFFALO, July 11—According to Orson E. Yeager, chairman of the contest and runs committee of the Automobile Club of Buffalo, the following are among the entries to the 300-mile reliability tour which will be run by the club September 7, 8, 9 and 10: The Poppenberg Automobile Company, Buffalo, two cars; Reo, touring class; Overland, runabout class; Meyer Carriage & Auto Company, of Buffalo, Pullman in the touring car trophy; Pullman Motor Car Company, of York, Pa., Pullman in the touring car trophy; Columbia Motor Car Company, of Hartford, at present undecided as to class entry; Regal Automobile Company, of Buffalo, Regal car in touring car class; Maxwell-Briscoe Buffalo Company, Maxwell car and an additional entry.

Meeting of Band of Gypsies Out of Bloomsburg, Pa.

Virginians Object to City Auto Tax

RICHMOND, VA., July 11—At a recent meeting of the Richmond Automobile Club unqualified endorsement was given by that organization to an ordinance now pending before the City Council which will prohibit persons under eighteen years of age from driving cars in the city.

The club entered earnest protest, however, against the proposed levying of a tax of $1 on all persons driving a car. The City Council is now preparing to pass an ordinance regulating the kind of horns to be used on all autos within the city limits.

William F. Gordon has arrived here after an automobile trip of 2,279 miles. In the party were Mr. Gordon, his wife, W. Douglas Gordon and Miss Mabel Walker. The trip was begun June 18 and was most delightful.

New York State had the muddiest roads encountered on the trip, while the roads between Wheeling, W. Va., and Pittsburg, Pa., were the roughest. Other States visited were delightful as far as roads were concerned.

Automobile News from the Boston Field

BOSTON, July 11—The Fisk Rubber Company, Chicopee, has closed a deal with a prominent Boston real estate man to erect a new building on Boylston street, in the heart of the motor colony. Work will be started at once. This will make four new buildings upon which work will be going on simultaneously for motor concerns, others being the Thomas, Fiat and Hartford Rubber Company.

The repair department completed for the Ford branch in Boston has been turned over to the company. It is a three-story concrete building, giving 17,000 square feet of space. The parts are on the first floor, repair department on the second and storage facilities for about 65 cars on the third. It is located in Cambridge, just over Harvard bridge. Manager Charles E. Fay has placed H. E. Partridge in charge of it.

Bay State A. A. members with their families, numbering more than 50, had their annual outing Saturday at Bedford, Mass., where the day was spent in athletic sports, followed by a dinner in the evening. It was a delightful outing.

The Rawles-Cobb Company, dealers in naval and mechanical supplies, has opened salesrooms for the Johnson cars, made in Milwaukee, at 741 Boylston street. The firm will sell both the pleasure and commercial vehicles, and expects to do well with this well-known make of automobile.

R. M. Daniels, manager of the Boston branch of the Studebaker Company, has resigned and the Studebaker interests will be looked after in future by the E-M-F officials, Charles A. Malley and B. N. Crockett. The E-M-F salesrooms will be enlarged and both lines will be handled from the one place, while the company will not have to build a garage as planned, but will use the new Studebaker one.

Plan to Offer $50,000 in Cash Prizes

LOWELL, MASS., July 11—While arrangements for holding a big race meeting on the Merrimack Valley course this fall are still in the tentative stage, plans are being projected that are aimed to bring about one of the most striking meets ever held in the United States. Last spring it was announced that no national championship races would be conducted at Lowell this year, and later preparations were made looking to the holding of a race meeting September 15-17, but at present John O. Heinze, president of the Lowell Automobile Club, and a number of progressive citizens of Lowell are contemplating a meeting at which $50,000 in cash prizes will be hung up and an entrance fee of $5,000 will be charged.

Hartford Valley, on the road to Wilkes-Barre

The plans are still in embryo, but it is said that active preparations to improve the course, bank and widen the famous letter "S" turn and the legal preliminaries are being made.

Rush Work on Marquette Buildings

SAGINAW, MICH., July 11—Foundations for the Washington avenue buildings of the Marquette Motor Company are being rushed and the structures probably will be completed within three months. All the mechanics who can be obtained are working on the erection of the factory. Property in the vicinity is enjoying a decided boom and prospects are that street car service will be extended to the vicinity. Manager Willett estimates the minimum number of employees for the plant at 1,000.

Race Meet for Atlanta Speedway

ATLANTA, GA., July 11—With a sanction granted for July 23 and with a tentative schedule of events drawn up, the Atlanta Speedway Association is soliciting entries for a local speedway meet to be held on the Speedway track. The program includes 15 events and offers a good variety. The races range in length from two miles to twenty and include offerings for all classes, from the smallest to the free-for-all.

Error in Hudson Output—Owen Plant at Detroit

Reports of the sale of cars this year have been so confusing, due to the large number of naughts employed, that mistakes are relatively easy to make, which is best illustrated by the following occurrence: In setting up an advertisement a comma was misplaced in a statement of the total of cars contracted for so that they read as follows: "46,00." A proofreader, noting that the comma was after the 6, figured out that there should be another naught, and he changed the copy to read "46,000." It never occurred to the proofreader that the comma was misplaced, but as a matter of fact the right expression is "4,600." The Hudson Motor Car Company, Detroit, Mich., wishes to let its patrons know that its cars contracted for hover around 4,600 automobiles, but it does not expect to reach the 46,000.

In the description of the Owen 1911 product, which appeared on pages 6 and 7 of THE AUTOMOBILE of July 7, it was erroneously stated that the plant is located in Indianapolis, whereas it is well known that the Owen factory is a Detroit landmark.

A Row of Hangars on a French Aviation Field, Showing System of Storing the Machines

Aviation News of the Week

WITH his gasoline reservoir as dry as a New Yorker's throat is supposed to be on Sunday, Walter Brookins coasted down from an elevation of 6,275 feet in a Wright aeroplane and landed on the beach in safety after breaking the world's record for high flight in a heavier-than-air machine. The trial took place last Friday at Atlantic City in the presence of an assembly estimated to be fully 25,000. The first announcement made after the completion of the flight was that a height of 6,175 feet had been attained by the aviator, but subsequently the figures were amended, making them 100 feet greater.

Brookins' total time in the air was 1 hour, 3 minutes and 30 seconds. Starting on his official trial at 6:08, he pointed his machine upward at a moderate angle and for 55 minutes he swung back and forth in a spiral circle, mounting ever upward until the man in the big machine seemed no bigger than a pinpoint. After he had been in the air for 51 minutes, observations from the earth showed that the aeroplane was 5,680 feet in the air and was still rising steadily. At this point Brookins was seen to point the plane downward and then back again to the rising position. For five minutes more he continued to rise, and then poising gracefully, the airship swooped toward the beach on a long, gentle angle. Swifter and swifter the plane shot downward until those below held their breaths for fear that the daring youth and his machine would be dashed to bits. Then the plunge was halted and the aeroplane regained its horizontal position and seemed to float along parallel with the surface of the ocean about 500 feet above. Then in a series of short spiral plunges and swings Brookins brought his machine to the beach, landing in perfect form within 100 feet of the start.

He will be awarded a prize of $5,000 by the Atlantic City Aero Club in case his record is not excelled before the present meeting comes to a close.

After landing Mr. Brookins gave a summary of his experiences. Prior to the official trial he had taken a preliminary spin to test the barograph, an instrument to measure height, and also to tune up his motor and machine. Just before 6 o'clock the announcement was made that all was ready, and instantly a big crowd assembled, hampering the arrangements to a certain extent. But sharply at 6:08 the aviator gave the signal to let go, and with a rush the plane darted away from the station. Having attained a comfortable height, he remembered that he had not taken the precaution of replenishing his supply of gasoline, but as the guage showed plenty in the reservoir, he determined to go on and break the record if possible. At 1,800 feet he swung around in a wider circle and mounted rapidly into the high-flying clouds. At this point he was lost to sight of the crowds below and for a time he confessed he was out of his calculations and unable to estimate his position with any degree of accuracy. It grew very cold after passing above the clouds and even the brilliant summer sunshine did not seem to have much potency at the higher altitudes.

Mounting steadily to 6,100 feet, according to the barograph, Brookins again consulted his gasoline gauge and found that his supply was running very low. Then his motor began to miss from lack of fuel and the aviator was forced to the expedient of halting his rise and tipping the plane downward so that the gasoline in the bottom of the tank might feel the force of gravity and flow more freely into his carbureter. When the missing cylinders began again to exert their power Brookins tilted up his planes and renewed his ascent.

When the barograph showed 6,175 feet the motor again began to miss and the aviator shut down and prepared for his long, plunging dive back to earth.

Down the hill of air the machine coasted, gathering momentum from the power of gravity and slipping along at a dazzling rate of speed. The descent commenced at 7:04, and seven minutes later the aeroplane was at rest upon the beach, while the crowds gave vent to the biggest kind of an ovation to the chance-taking young man.

Clifford B. Harmon, the amateur aviator, has been making a series of interesting trials of his Farman biplane at Hempstead Plains during the past week. Mr. Harmon tried out his machine with a full equipment of pontoons before a big crowd Saturday in preparation for his flight across Long Island Sound. On Monday last Harmon made his attempt to fly across the Sound from the aviation grounds to the country home of his father-in-law, in Greenwich, Conn. In his first start he found that the pontoons he had added to his machine spoiled its equilibrium. He had been in the air but a very few minutes on his second attempt when his motor began to skip. With but three cylinders working he was forced to a hurried descent, from which he fortunately emerged with nothing worse than a shaking-up and a smashed machine. A race is being arranged between Mr. Harmon and Capt. Baldwin from Governor's Island up the East and North Rivers, circling Grant's Tomb, the contestants to go in opposite directions.

The new world's record marks for speed and distance which were set at Rheims last week were discussed widely in aero circles. The speed mark of nearly 70 miles an hour was ackuowledged to be the most important by aviators who have had wide experience. Their opinion is a unit that the high speed attained in France foreshadows much higher attainable speeds there and elsewhere. The significance, according to the students of this phase of the air-flying problem, lies in the fact that if the aeroplane can be developed so that a speed of 120 miles an hour is demonstrated, the aeroplane will have triumphed over the uncertainty and danger of sudden, high and uneven winds. When such development has been achieved they point out that travel via the air will take rank in safety with that of travel in express trains on the earth's surface.

In the same biplane with which he made his phenomenal Albany-New York trip, Glenn H. Curtiss, on Monday last, at Atlantic City, established a record for a 50-mile flight in America. His time was 1 hour, 14 minutes and 59 seconds, and the course was 2 1-2 miles in length, from Chelsea to the Steel Pier. He averaged about 40 miles an hour.

Charles K. Hamilton, hero of the first round-trip flight between big cities, has broken with Glenn H. Curtiss on account of some alleged affront to his dignity at Atlantic City. Hamilton's engine had been acting balkily for some time and there was some hitch about the renewal of his motor by Curtiss. Without warning, Hamilton stored his machine and notified Curtiss that he was no longer working. It is said that he will operate another type of biplane in the immediate future.

Auto Decked with 10,000 Roses

At the Portland (Ore.) Rose Festival, held early in June, one of the most striking exhibits was a Studebaker-Garford "40," which appeared in the parade. The automobile was covered with 10,000 roses and a quantity of green ferns and grasses. The form of the decorations of the Studebaker-Garford was that of a giant gondola.

Studebaker-Garford "40" Featured the Portland Festival

The exhibit attracted an immense amount of comment along the line of the parade. The Rose Festival is an institution peculiar to the Pacific coast, where it corresponds in large measure to the Mardi-Gras of New Orleans and other Southern cities.

Los Angeles Frames Contest Program

Los Angeles, July 11—The activity in motor racing circles this coming fall in California will more than make up for the dormant state of the sport this summer.

The first race on the coast will be the San Francisco road race over a course which will take the cars through Golden Gate Park and up the hill of the recent hill climb. Many cars will be entered, some of which will be sent to Los Angeles for the Santa Monica race, which follows on September 24. Los Angeles will be represented by good talent.

The annual Los Angeles-Mt. Baldy road race was originally set for September 18, but as the Santa Monica will follow the Saturday after, there is a conflict which will make a difference in one of the events. It is the belief that the run will be more welcome later on and promise of a better "test" is given.

In October the Motordrome will resume business with a national circuit meet. This will be followed by racing in November and again during the Christmas holidays. It is possible that the meet in October will be a 24-hour race.

November will see the third annual running of the Los Angeles-Phœnix race.

Ten cars were entered last year and fully that many are expected to compete this season.

The race really should start in Phœnix and finish in Los Angeles as the Arizona town failed to show the least enthusiasm. But, regardless of these matters, it is a grand race, which takes the cars over a course where they buck hub-deep sand for 100 miles.

Brooklyn Reliability Postponed

The reliability contest of the Brooklyn Motor Vehicle Dealers' Association, scheduled for July 19 and 20, has been postponed until August 9 and 10. Forty tentative entries have already been made.

Sentinel Trophy Run Looms Large

Milwaukee, July 11—The first annual tour of the Wisconsin State A. A. for the Milwaukee *Sentinel* Trophy promises to bring out a larger field of contestants than any State tour in America up to this time. There are already twenty entries in the hands of Chairman George A. West, who is confident that there will be thirty-five starters at the least. On July 16 all contesting cars will be brought to the Auditorium for inspection by the technical board, under David Beecroft, of Chicago.

The start will be made at 8 o'clock Monday morning, July 18. More than 780 miles will be covered in the five days' run covering practically the entire State. In addition to the $800 *Sentinel* Trophy, the State association will award gold medals and certificates of merit to all cars scoring not less than 97 per cent. of the winning car's score. Cars listing at $1,601 and over will maintain an average speed of 18 miles an hour; cars listing at $801 and up to $1,600 will run sixteen miles, while those listing under $800 will follow a fifteen-mile schedule.

Philadelphia Motordrome Progressing

Work on the Philadelphia motordrome at Clementon, N. J., has taken wonderful strides in the past fortnight.

Large gangs of laborers, carpenters, mechanics, etc., have been set to work for the purpose of converting this now uncultivated piece of country into a tremendous drome for motor car races and aviation meets.

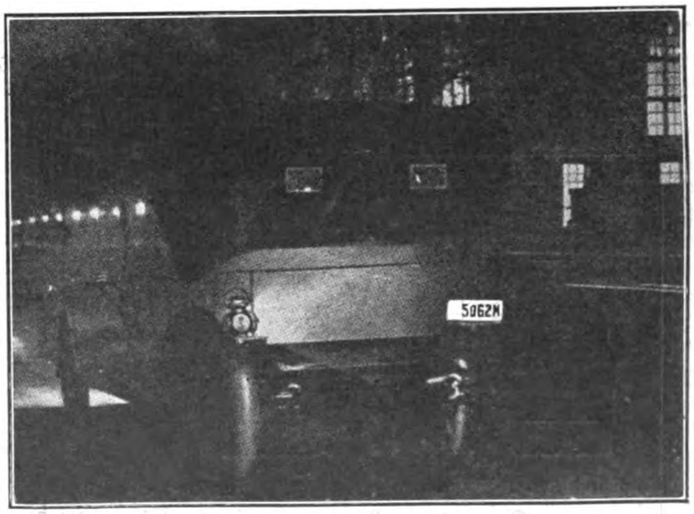
The six hangars which are being erected on the grounds for the storing of aeroplanes belonging to members of the Aero Club of Pennsylvania are near completion.

Reliability Run for Motor Trucks

A motor truck reliability run, to be held August 12-13, under the auspices of the Philadelphia *North American*, is the first event of its kind ever attempted. The contest has official sanction from the Contest Board, and its conditions have been attractively framed. The route from Philadelphia to Atlantic City will be long, varied and populous enough to test the commercial vehicles under the eyes of a considerable section of the public. The Quaker City Motor Club will co-operate with the newspaper.

Helps Motor "Cops" to Trace Offenders

In the current issue of *The Packard* is shown a new kink in the location of the rear license tag—on the right fender, with the tail light so disposed on the left fender that it casts its direct rays upon the number plate, illuminating it distinctly.



Motor "cops" can't go astray with rear lamp in this position

A New Controlling Mechanism for Motor Vehicles

LAWRENCE WHITCOMB, Treasurer of the National Brake and Clutch Company, Boston, Mass., has invented an improvement in controlling mechanism of a motor vehicle, whereby the latter is prevented from being driven at a speed in excess of a predetermined rate, while leaving the motor free to develop its full capacity when the speed of the vehicle falls below the predetermined rate. For this purpose a moving body of liquid is employed, which is responsive to the speed of the vehicle and which actuates or controls the supply of gas or explosive mixture to the motor or which controls the ignition. The moving body of liquid is put in motion by the running gear of the vehicle and may be operatively connected with a throttle valve governing the supply of gas to the motor, or it may be operatively connected with a circuit controller in the igniter circuit. Provision is made for varying the maximum speed limit at which the vehicle may travel, and provision may also be made for utilizing the moving body of liquid for applying the brakes to the vehicle when the maximum speed limit is reached.

In Fig. 1, the moving body of liquid controls a throttle valve in the gas supply pipe 20 leading from the carbureter 21 to the cylinders of the motor b, the pipe 20 being shown as provided with four branches 22. Referring to Figs. 3, 4 and 5, the throttle valve is shown as a hollow piston valve 25 provided with a central wall or partition 26 through which is extended a piston rod 27, the said piston having a series of ports 28 in its circumference, which are adapted to register with corresponding ports 29 in a cylindrical shell or sleeve 30 located in a valve casing or fitting 31 provided with a gas inlet port 32 and with a gas outlet port 33. The inlet port 32 is connected with the carbureter 21, and the outlet port 33 is connected with the gas inlet pipe 20 leading to the cylinders of the motor. The valve shell or sleeve 30 is fixed within the casing 31 and is open at its ends, and the hollow piston valve is also open at its ends, so that gas can pass into the valve from the casing 31 at all times and pass to the motor when the ports 28 in the valve register with or uncover the ports 29 in the shell 30. The valve 25 is acted upon by a spring 35 so as to open the ports 29 and supply gas to the motor as long as the speed of the vehicle is below the maximum set. The valve 25 is moved to close the ports 29 and shut off the supply of gas to the motor, when the speed of the vehicle reaches the maximum determined upon and for this purpose, the valve stem or rod 27 co-operates with a diaphragm 38 of leather or other suitable material, which may be provided as shown with a metal bearing plate or button 39, and which is interposed between the casing or fitting 31 and a liquid containing chamber or well 40, herein shown as in screw-threaded engagement with the valve fitting or casing 31. The liquid chamber or well 40 may be designated a pressure chamber, which is provided with a liquid inlet pipe 41 extended up into it, and with a liquid outlet pipe 42 leading from the bottom of the pressure chamber, the said pipes communicating with a liquid pump, which is operatively connected with the running gear of the vehicle to be driven thereby only when the vehicle is in motion. In the present instance, one form of liquid pump is shown, which comprises a casing 43 containing two intermeshing gears or bucket wheels 44, 45 (see Fig. 7), which are mounted upon suitable shafts 48, 49, within the casing, one shaft as 48 being extended through one side of the casing 43 into a second casing 50, wherein it has mounted on it a gear 51 in mesh with a gear or pinion 52, which in turn meshes with a gear 53 fast on the driven shaft d, (See Figs. 2 and 10). The pump casing 43 is provided with an outlet pipe 55, which is extended to the pressure chamber and is connected with or forms part of the liquid inlet pipe 41 therefor. The pump casing 43 is provided with a fluid inlet pipe 56, which in the present instance is connected with a liquid supply tank or reservoir 57 (see Fig. 1), which is connected by a pipe 58 with the outlet chamber 59 of a regulating device shown separately in Fig. 6, and consisting of a casing 60 having a partition wall 61 forming the outlet chamber 59 and an inlet chamber 62, which are adapted to be connected by a port 63 in the partition wall 61, with which co-operates a valve 64. The inlet chamber 62 has connected with it the outlet pipe 42 for the pressure chamber 40. The valve 64 is provided as shown with a threaded stem 65, which is extended through the casing 60 and into a chamber 66 having a removable wall or cover comprising a metal ring 67 and a glass disk 68, through which numbers on the bottom 69 of the chamber and indicative of speed units, such as miles, may be seen. The valve stem 65 has attached to it a handle or pointer 70, which registers with the numbers referred to and which may co-operate with studs or pins 71 depending from the ring 67 and forming locking devices for the said pointer or hanger to retain the latter and the valve 64 in their adjusted positions for a purpose as will be described. By turning the handle 70, the valve 64 may be moved toward or from the port 63 so as to restrict or enlarge the flow of liquid through the port and thereby increase or decrease the pressure of the liquid in the chamber 40 upon the diaphragm 38, with the corresponding result of diminishing or increasing the amount of gas supplied to the engine. The cover of the chamber 66 in which the regulating apparatus is located may be sealed or locked to unauthorized persons by means of a lock 73.

In the arrangement of the apparatus herein shown, the valve 25 is represented as independent of the usual throttle valve not shown, but which is under the control of the operator of the vehicle, and when the vehicle or car is at rest, the valve 25 is opened wide by the spring 35.

When the car is in motion, the liquid pump is driven from the running gear of the vehicle and takes the liquid from the supply tank 57 and forces it into the pressure chamber 40, from which it passes through the pipe 42 into the chamber 62 of the regulator, and if the valve 64 is open, said liquid passes through the port 63, chamber 59, and pipe 58, back to the supply tank or reservoir 57. By varying the position of the valve 64 with relation to the port 63, the circulation of the liquid may be varied so that more or less liquid accumulates in the pressure chamber 40 and the pressure of the same upon the diaphragm is varied, so that the valve 25 is operated to supply more or less gas to the engine according to the maximum speed it is desired the vehicle should travel. For instance, let it be supposed, that it is desired to limit the maximum speed of the vehicle to twenty miles an hour. In this case, the owner of the vehicle or other authorized person sets the handle or pointer to register with the number 20 of the regulator. This movement of the handle causes the valve 64 to be moved with relation to the port 63, so as to restrict the flow of the liquid through the regulator and cause the liquid to accumulate in the chamber 40, until such pressure has been increased sufficiently to move the diaphragm 38 and the valve 25 so as to diminish the supply of gas to the motor to such extent as will prevent the speed of the vehicle exceeding the maximum set, say twenty miles per hour, and if desired, the valve 25 may be entirely closed at such time. When the speed of the vehicle drops below the maximum, the pressure in the chamber 40 diminishes, and allows the spring 35 to move the valve 25 in the opposite direction and increase the supply of gas to the motor.

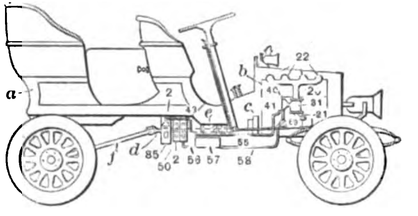


Fig. 1—Side elevation showing application of speed regulator

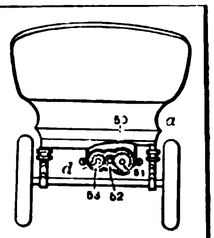

Fig. 2—Cross section on line 2-2, Fig. 1, with body in elevation

While the vehicle is traveling below the maximum speed, the operator is free to develop the full power of the motor if desired, as for instance in climbing hills or traveling over sandy roads. The spring 35 may be of such strength as will hold the valve 25 wide open until the vehicle is traveling at the maximum speed, at which time, the pressure in the chamber 40 has increased sufficiently

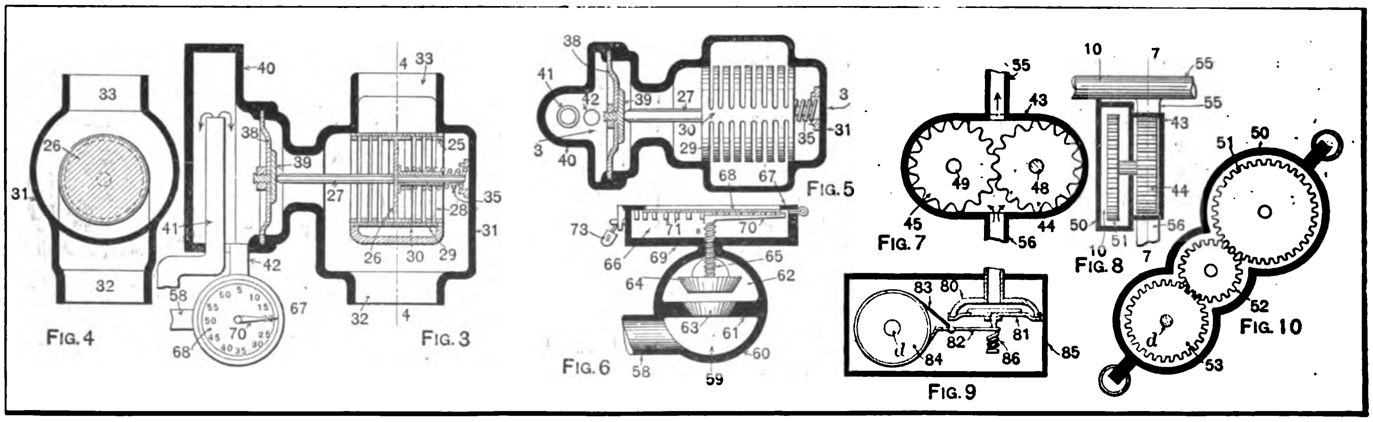

Fig. 3—Sectional detail of throttle valve and operating mechanism. Fig. 4—Cross section on line 4-4, Fig. 3. Fig. 5—Partial plan and section of throttle valve. Fig. 6—Showing details of the speed regulating device. Fig. 7—Section on line 7-7, Fig. 8. Fig. 8—Details of the liquid pump. Fig. 9—Sectional detail of liquid-pressure brake. Fig. 10—Section on line 10-10, Fig. 8

to overcome the spring and completely cut off the motor from the gas supply, or if desired the spring 35 may be adjusted to permit of a gradual closing of the valve 25. If desired the liquid pressure may also be utilized to apply a brake to stop the vehicle when the maximum speed limit is reached, which may be accomplished as herein represented, by connecting the pipe 55 with a chamber 80 (see Figs. 1 and 9), having a diaphragm 81, which acts on a lever 82 connected with a band brake 83, which engages a brake-wheel 84 fast on the driven shaft d. The brake band 83 and its operating mechanism may be located in a suitable case 85. When the fluid pressure reaches the point at which the valve 25 is closed, it may be sufficient to actuate the diaphragm 81 and apply the brake 83 to the wheel 84, and when the pressure is reduced, the brake may be released by the spring 86 acting on the sleeve 82.

Among the claims made for this device are: A valve to control the supply of explosive medium to said motor, a chamber containing a diaphragm operatively connected with said valve, a liquid pump driven by said mechanism and connected with said chamber to create a pressure upon said diaphragm by a moving body of liquid, means for regulating the liquid pressure upon said diaphragm to operate said valve and control said motor when the speed of the vehicle reaches a predetermined point, a brake, and a diaphragm operatively connected with said brake and responsive to pressure of the said moving body of liquid, substantially as described; a governor means for operatively connecting the governor with the vehicle to cause the governor to respond to the speed of the vehicle at all times while the vehicle is in motion and irrespective of the speed of the motor, and means to operatively connect said governor with said diaphragm.

Trade Notes of Interest to Maker, Agent and Garage Keeper

Adolph Eastman will sever his connection with the Wagner-Field Company on July 16.

H. G. Twelvetree has taken the active management of the Cleveland Rambler agency.

Manager F. S. Rockwell, of the Toledo Buick branch, has taken the agency for the Reliance motor truck.

The Glidden Garage Company has been incorporated in Buffalo; capital stock, $10,000. Directors: Oscar, Mary E. and Harry C. Meyer.

The R. E. Hardy Company has announced that the manufacture of Sta-Rite ignition plugs in Canada has commenced at its Windsor factory.

The New England Motor Vehicle Company, of Boston, has taken on the Parry car, the agency for which had been discontinued a few months ago.

Gray & Davis, makers of high-grade lamps, have made the announcement that they are shipping the Cadillac Motor Car Company, of Detroit, four carloads of lamps each month.

The Porter-Lovette Auto Company has just opened a fine new garage at 548 Grand River, corner Myrtle, Detroit. This is a one-story, concrete building, with a capacity of 75 cars.

V. M. Palmer, chief engineer of the Selden Motor Vehicle Company, Rochester, N. Y., has resigned his position to accept a similar place with the Sheldon Axle Company, of Wilkes-Barre, Pa.

Charles E. J. Lang, of the Rauch & Lang Carriage Company, is now on a tour around the world. He will visit many of the larger cities of the world, and incidentally will open up markets for the electric car made by the firm.

The Mercer Automobile Company, of Trenton, N. J., announces that the price of its 1911 stock model, including full lamp equipment, tools and repair kit, will be $2,150. Touring car, toy tonneau and Speedster are the chief styles.

The General Motors Company will make extensive improvements on the Elmore factory at Clyde, Ohio. A new machinery building, 200 feet wide and 250 feet long, will be erected, making the main factory structure 660 by 300 feet.

Ground was broken the past week for the Seattle Taxicab Co.'s new garage at Ninth and Pike streets. The structure will be built of brick and the cost will be $25,000.

George F. Reim, formerly with R. R. Kimball, has secured the Omaha Cadillac agency and formed a partnership with W. R. Drummond to handle the Cadillac car. The new firm will occupy the garage of C. F. Louck at 2550 Farnum street.

Joe Downey, the well-known race driver of Boston, has been spending some time at Newburyport, where William Hilliard is experimenting with a Burgess aeroplane, and he expects to go into the flying business as soon as he can get a machine.

The C. A. Shaler Co., Waupun, Wis., manufacturers of the Shaler Electric Vulcanizers, has awarded contracts for the construction of a new factory. The main building is to be of concrete, and electric power transmission is to be used exclusively.

C. J. Merbach and Gordon S. Morse will build a large garage, 100 by 100 ft. in dimensions, on Watson street, near Woodward, Detroit, with a machine shop in connection. This will be an all-concrete and steel building, and will accommodate 75 cars.

The annual outing of the employees of C. F. Splitdorf at Schroeder's Unionport Park, Saturday, June 25, was largely attended. Prize bowling, dancing and athletic events was the order of the day, the weather was perfect and the affair enjoyable.

George L. Osborne has been appointed sales manager of the Boston branch of the Peerless Company, while H. C. Mayo has been placed in charge of the outside business in New England. Manager John L. Snow announces that the new building for the branch will be ready for occupancy about August 1.

Frank F. Matbeson, general manager of the Matheson Motor Car Company, is slowly recovering from an operation for appendicitis. On the occasion of his last visit to New York on June 18, Mr. Matheson was taken suddenly ill in the Knickerbocker Hotel. He was promptly removed to Wilkes-Barre, Pa., and there underwent an operation for the removal of his appendix.

C. L. Simmons has associated himself with the Lozier Motor Company, and has started on an extended trip throughout the South and West, visiting old agencies and extending the Lozier field of operation into new territory.

B. F. Hoffman, Jack Calvin and J. M. Calkins have formed a partnership at Bryan, O., for the purpose of erecting and operating a garage and repair shop in that city. The building, which will be located just east of the Jefferson Hotel, will be 44 feet by 130 feet in dimensions, and of substantial construction.

The Tokheim Manufacturing Company, of Cedar Rapids, Iowa, has opened a branch office in Detroit at 300 Woodward avenue. This is in charge of R. P. Hanson. The company makes a line of gasoline and oil handling apparatus, both in the hand-actuated and vacuum-operated types, as well as all parts for oil storage and handling.

The Yuster Axle and Transmission Company, of South Bend, Ind., has been absorbed by a syndicate consisting of J. C. Paxton, president of the Merchants' National Bank, and several others. Mr. Yuster retains an interest as vice-president. The property will be consolidated with the Clover Leaf Machine Company. A new factory with 75,000 square feet of floor space is projected.

A Metz car, made at Waltham, Mass., is said to have traveled from Iron Hill, Md., to Winchester, N. H., traversing nine States in a single day. The States covered were Maryland, Delaware, Pennsylvania, New Jersey, New York, Connecticut, Massachusetts, Vermont and New Hampshire. The tour touched 18 cities having a population of more than 20,000, or an aggregate of over 7,000,000.

Albert Bennet, who has been sales manager for the Colt-Stratton Company, Eastern distributors for the Cole "30," has taken charge of the Henderson Motor Sales Company, of Indianapolis, and in addition to his work of handling the Cole car in the East will look after the Westcott "40," which is distributed through New York State and New England by the recently organized Dunlop-Taylor Motor Company.

Seen in the Show Window

ACCESSORY makers are now recognized as of the greatest importance to the industry, they being specialists, and the trade demanding a larger output than the makers of cars are able to cope with. The Cotta Transmission Company, Rockford, Ill., is handling work of this character on a large scale, and as an illustration of the character of the product being turned out at this plant, one specimen (AE) is here presented. The design is stable, the material used is fitting, and the character of the workmanship is up to a high standard.

NOT to mention the sanitary aspect of the matter, the idea of a speaking tube as a medium of communication between passenger and chauffeur has many objections. It is difficult to speak and to hear through a tube, and the electric devices which have supplanted the latter, in a measure, have the defect of a limited range of instructions, so that it frequently becomes necessary to open the window when the passenger desires to talk with the driver. The Hall's Rigid Motor Flap (AF), now being marketed by S. F. Edge (Ltd.), 14 New Burlington street, London, Eng., meets these objections very thoroughly. It is a neat and solidly made metal frame, finished in nickel or brass, and easily opened by touching a button at the bottom. The flap is held open by means of a spring.

AMONG the latest devices for transmission work is the pneumatic transmission here shown (AG), which is made by the Pneumatic Transmission & Clutch Company, Los Angeles, Cal. This device provides mechanism to take the place of the usual flywheel, clutch and transmission gears.

In accomplishing this two members are used: the one connected directly to the engine, being ordinarily the driving member, and the other connected to the shaft or driven member. On the driving member is mounted a plurality of cylinders in which pistons attached to the driven member are adapted to reciprocate. These pistons are eccentrically connected to the driven shaft while the cylinders are concentrically arranged around the axis of the driving member, so that upon any relative rotation of the members the pistons will be reciprocated in the cylinders.

By retarding the action of the pistons in the cylinders, the driven shaft may be more or less rigidly locked to the driving member; and this retarding or locking means is compressed air in the cylinders behind the pistons. Openings in cylinders are provided which may be restricted, through which the air must pass, and thus the amount of locking effect between the two members may be regulated at the will of operator. Automatic valves are provided so that air is taken into cylinders from atmosphere and is pumped out through these restricted ports. The ports are connected with a pressure reservoir into which the air is pumped.

When it is desired to start the engine, or run the car in either direction, air is thrown from this reservoir into cylinders through the valves and the clutch-transmission member becomes a rotary air engine.

The piston chamber valves operate automatically, and the entire mechanism is controlled by one three-way valve located between clutch and storage tank by which the locking effect of clutch or driving effect of air engine is operated at will.

Air pressure in tank is automatically kept constant through a by-pass valve.

(AF)—The Halls Rigid Motor Flap—A Needed Convenience

(AG)—Pneumatic Transmission Which Replaces Fly-Wheel, Clutch and Gears

(AH)—The Detroit Light-Weight Engine for Aeroplane Work

(AI)—Holzer-Cabot Idea of Magneto Drive by Friction from Motor Fly-Wheel

(AJ)—The Economy Perfection Automatic Battery Charger

THE demand for a low-priced, light-weight motor for aeronautic purposes has resulted in attracting the attention of numerous designers. Among them, the Detroit Aeroplane Company has perfected and is manufacturing a two-cylinder, air-cooled engine (AH) of the double-opposed type, four-cycle, 5-inch bore and 5-inch stroke, with a speed range of from 700 to 1500 R. P. M., and developing between 20 and 30 horsepower. The complete engine weighs but 98 pounds. The company will make and attach propellers to motors on special request, and keeps in stock sizes between 5 and 8-feet diameter and 3 to 7-feet pitch.

JUST now the question of magneto ignition is being taken up by many owners of old automobiles, and in some of the used models it is quite a problem to apply a magneto. Referring to (AI) of the Holzer-Cabot Electric Company's magneto ignition equipment, it will be observed that provision is made to drive the magneto from the flywheel of the motor. A friction drive is provided, and the method of the use of the principle is such that the result is satisfactory. The plant of the company at Boston, Mass., is well equipped to do work of this character.

THE general adoption of electricity for lighting automobiles and motor boats has been retarded by lack of a proper and dependable current supply. To remedy this defect, the Economy Manufacturing Company, of Economy, Pa., has introduced the Perfection Battery Charger (AJ), which automatically keeps the storage battery always supplied at practically no expense for maintenance and obviating the necessity of removing the battery from the box. Either friction, gear or belt drive may be used with this handy device.

VOL. XXIII NEW YORK—THURSDAY, JULY 21, 1910—CHICAGO No. 3

THE AUTOMOBILE

Gasoline Reigned During Elks' Week at Detroit

THE CADILLAC FLOAT WHICH WON THE GRAND SWEEPSTAKES IN THE PARADE

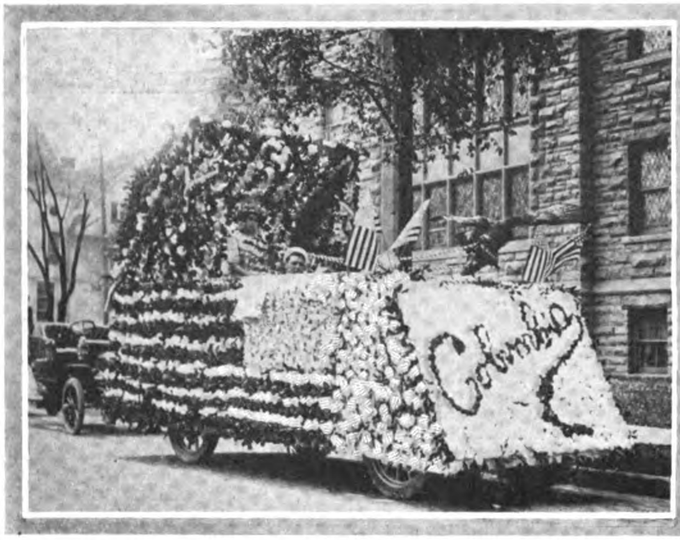
DETROIT, MICH., July 18—Gasoline reigned in Detroit last week. The supremacy of the gasoline motor was strikingly demonstrated on land and water and in the sky overhead. No other factor contributed so largely to the entertainment of the host of visiting Elks. What with speed exhibitions by some of the word's famous drivers, aeroplane flights at the State fair grounds, motor boat races on the river and one of the greatest auto parades the world has ever seen, the visitors must have been impressed.

There were a few less than 2000 automobiles in line Friday afternoon. The parade was about a dozen miles in length and as a spectacle was well worth seeing. The entire route, traversing nearly eight miles, was lined with spectators and a goodly crowd filled the grandstands on Washington boulevard.

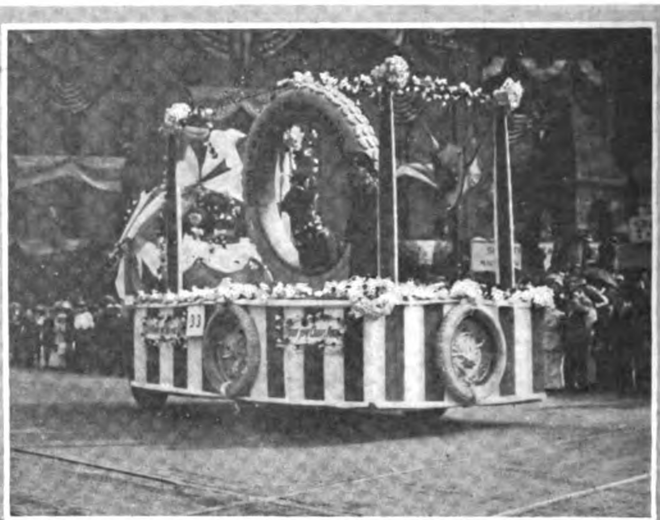
Practically all the local manufacturers took advantage of this opportunity and most of them made a creditable showing. An unusual number of 1911 models were displayed, high officials of the various companies driving them in many instances. There were some 40 sections in all.

The Cadillac Motor Car Company captured the grand sweepstakes prize; a 30-inch silver loving cup with gold lining, with its magnificent float representing Chevalier Cadillac receiving from Louis XIV. of France a commission to found a colony at Detroit. It was a reproduction in life of a painting that hangs in the city hall and which was presented to the city by the French Government on the occasion of Detroit's bi-centennial celebration.

A Chalmers "30," driven by Mrs. R. D. Aldrich, won the prize offered for the best decorated car driven by a woman. In the gasoline pleasure car division, T. A. Belinger, in a Warren-Detroit, won the first prize; Will B. Wreford, local agent of the Columbia, the second, and the third went to the driver of a Sibley "20." In the commercial-car division the first prize went to the Welch-Detroit motor car for a strikingly realistic reproduction of a scene from the battle of "Bloody Run." The second prize went to a local furniture house, and the third to Morgan & Wright, whose float contained a boy in a swing suspended from the top of a huge tire.



Columbia, which captured second prize for gasolines



Morgan & Wright float in the commercial division

The parade brought out some surprises in the way of comic novelty, but none more original than that of the Michelin Tire Company, a pair of inflated rubber giants perched on a high pedestal. The figures assumed ludicrous positions as the car sped along, its locomotive whistle screeching incessantly. The Michelin company won a prize, and the only one in the comic section.

The Buick racing cars loomed conspicuously in the parade as they trailed along behind a car in which no less than 50 prize trophies were displayed. The official party, comprising Mayor Breitmeyer, Past Grand Exalted Ruler Sammis, of the Elks; Grand Secretary Fred C. Robinson, Grand Esquire A. J. Davis and Fred S. Burgess, chairman of the Elks' executive committee, rode in a Welch car at the head of the parade, directly behind the police escort in Fords. E-M-F cars made up four divisions and the Fords and the Hupmobiles two each. The Hudson Motor Car Company had about 60 cars in line. Robert K. Davis was marshal of the parade and rode in his purple and white Maxwell roadster, followed by his aids in their individual cars. The Regal "Plugger" was there with all its labels. "Garry" Herrmann, the new Grand Exalted Ruler of the Elks, rode in the Hudson "30" won by the Cincinnati ladies for making the best appearance in the big Elks' parade of Thursday.

Aside from its historical float and a fine showing of new cars, the Cadillac Motor Car Company displayed its enterprise by rounding up a half dozen or so of its earliest type, built in 1903, and having them driven in the parade by their owners under a banner bearing this legend: "Eight years of service and still going." The company says it has yet to hear of the first Cadillac car going out of commission.

In spite of a rather heavy track, some remarkably good speed stunts were pulled off at the Grosse Pointe race track Saturday afternoon at the free exhibition matches participated in by the members of the Buick team. There were 12 events on the program, which attracted a crowd of nearly 10,000. The aeroplane flights at the fair grounds drew less than 1000 Saturday, but this attraction wasn't free.

Burman, in his special, made the fastest mile of the day in 56 4-5 seconds. This was on a second trial. The time on the first trial was 59 seconds flat. But Louis Chevrolet carried off the lion's share of the day's honors, winning every event in which he was entered but one.

Both the General Motor Company's tented garage on the D. A. C. grounds and the United States Motor Company's "white city" out Jefferson avenue were put to good use by visiting motorists during the reunion, and the courtesy shown was greatly appreciated. The Sibley Motor Car Company also offered the use of its new building at Solvay and Mackey avenues to visiting motorists. The building is just completed and the company is moving in to-day.

Warren-Detroit, Winner of First Gasoline Prize

A Chalmers-Detroit float which attracted attention

The aeroplane flights at the State fair grounds Thursday, Friday and Saturday were the first exhibitions of the kind ever given in Detroit and were largely attended the opening day. Flights were made by Arch Hoxsey, Duval La Chappell and Walter Brookins, the latter of whom holds the world's altitude record, 6275 feet. No records were broken here and no attempt was made to break any, because of unfavorable conditions. While not aeroplaning, Mr. Hoxsey drove a Cartercar, placed at his disposal by George Reason, branch manager for the Cartercar company here. Between flights Leo Broker gave exhibitions with his "wind wagon," a cross between an aeroplane and a motor car, which proved as amusing as it was noisy. A race between the "wind wagon" and a motorcycle was an added feature of Friday's program, and the latter won by half a length in 1:41.2, going once around the mile course. The "wagon" is like an automobile in appearance, except for a huge propeller on the front end, which pulls the machine along when it revolves.

David Kerr, manager of the Kerr Machinery Company, has purchased the white and purple Maxwell roadster made especially for the use of Robert K. Davis, of the Maxwell-Briscoe-McLeod Company, during the Elks' reunion.

Walter E. Flanders, president of the E-M-F Company, emphatically denies a story that has gained wide circulation, that he is soon to leave the E-M-F to associate himself with E. LeRoy Pelletier, former advertising manager for the company, in the manufacture of a new style of automobile, propelled by four wheels turned by the motor instead of two.

"The story," said Mr. Flanders, "is without the slightest foundation in fact."

Incidentally Mr. Flanders announces that the company has about completed plans for the manufacture of commercial trucks, which will necessitate the erection of another addition besides the two now under way.

Accompanied by a brass band, 500 employees, for the most part foremen and department heads, from the seven plants of the E-M-F company boarded a special train Friday morning for a day's outing at Lake Orion as guests of the company. This was a part of the three days' vacation given the men with full pay.

With reference to the resignation of Mr. Pelletier, the story comes from New York that J. P. Morgan, who now controls the E-M-F, was displeased with the prominence given his name in the press accounts of the sale and the publicity "dope" given out by Mr. Pelletier's department. It is reported that Mr. Pelletier's $200,000 worth of stock has been purchased by the Morgan interests at par.

After negotiations of long standing, James J. Brady has disposed of his interests in the Chalmers Motor Company to Hugh Chalmers, president of the concern. Previously he disposed of his interests in the Hudson Motor Company, the Metal Products Company and the Fairview Foundry Company.

Overland Transcontinentalists

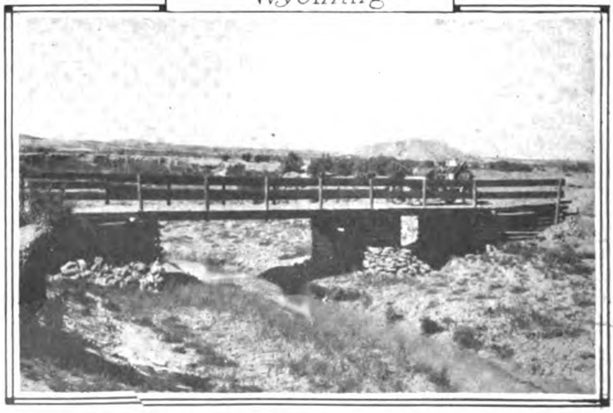
WESTWARD from the Wyoming-Nebraska State line the route of the transcontinental trip following the old Overland trail lies through some mighty lonely country. The accompanying pictures show its desolateness with remarkable clarity, but they can give no idea of the quality of the roads in bad weather, for they were taken after a long dry spell when the alkali and baked mould were packed hard as flint under a thin cushion of dust. Reports from the tourists show that the roads throughout Wyoming were an agreeable surprise as to condition.

Almost from one side of the big desert State to the other a range of yellow hills lies to the northward of the Overland trail. At Sherman the road crosses the continental divide, nearly a mile and a half above sea level. To the southward stretches a vast tangle of rugged mountains, comprising the backbone of the American continent, and as the tourists progressed on the almost imperceptible down-grade, through the wide valleys dotted with gray-green sage-brush, where for hours the only living objects within view were occasional bunches of cattle, a stray coyote or jackrabbit and a few antelope grazing on the sparse bunch-grass near the cattle, they received a foretaste of what they were to encounter further to the west.

The trails in the heart of the Rocky Mountains are sometimes miles in width, where the floor of a valley is as level as a billiard table for considerable distances. Then again they narrow down to a single roadway, and where the trails are used for heavy freighting, to and from mining camps, they may be deeply

Sunset on Prairie

Bitter Creek Bridge Wyoming



"Our Joy Ride"

Rapidly Nearing Their Goal

scarred and rutted. The arroyos, or dry washes, propound serious problems in transportation to automobile drivers, and the occasional streams all have beds that are entirely out of proportion to their size. Crossing either wet or dry washes is a trying matter for car and driver, unless adequate bridges have been constructed.

But west of Wyoming the mystery of the real desert encloses the tourist. The sharp snap in the air at dawn; the exceeding heaviness of the dew upon the sage-brush; the awesome silence of nature; the brilliance of the sunshine and the glare of the desert trails all have their part in impressing the traveler with their strangeness and unreality; but at night, when the blazing constellations seem only about as far away as the polished globes in the ceiling of a Broadway theater; when the majestic motion of the moon is distinctly apparent and the only sound to be heard is the snarling yelp of a distant prairie wolf, the smallness of mankind is borne forcefully in upon the mind of even a casual observer.

Nevada affords such a stage setting from the edge of the Great Salt Lake to the preliminary lifts of the Sierras. Entering this giant range from the east, the first sight of the saw-tooth ridge lying against the skyline is magnificent, and Miss Blanche Stuart Scott, of New York, in an Overland car which she has driven from New York, is just climbing that range at last reports. The tour is seven-eighths accomplished and while the final stretch is an exceedingly trying bit, it is no worse than some others.

Studebaker, South Bend—Offers Garford Models

DESPITE the fact that the Studebaker plant at South Bend extends over 101 acres, measuring floor space, the Garford models are made at the well-equipped Garford factory at Elyria, Ohio. The final finishing and tuning-up work, however, is taken care of at South Bend, and while the company turns out a wide variety of vehicles, including its well-known make of electric vehicles and a line of trucks, it proposes, nevertheless, to manufacture about a thousand Garford models for the coming season. The latest advices from the Garford plant are to the effect that the Model G-7 has passed so successfully through the 1909 and 1910 service that it will be continued, subject to such refinements as naturally would creep in in a progressive plant.

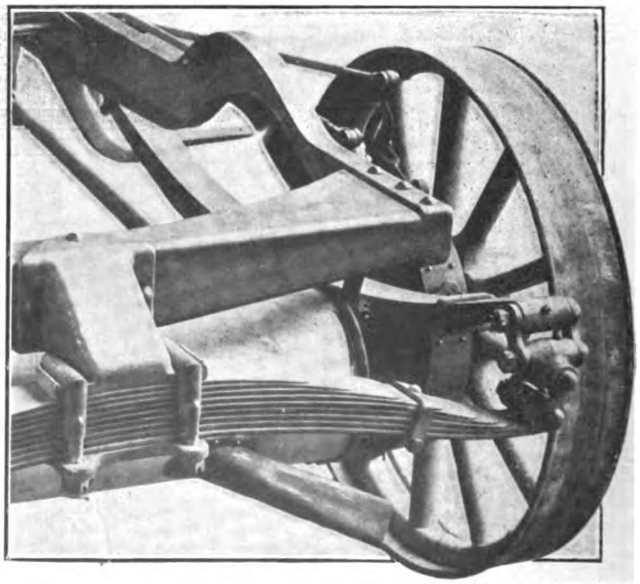
This model is offered with three types of bodies in the regular way, including a limousine at $5,000 that seats seven passengers, a touring car at $4,000 with the same seating capacity, and a speed car at $4,000 seating three. The equipment included with each of these models is two head lamps, two side lamps, tail lamp, shock absorbers, tool box with kit, coat rail, gasoline gauge, top irons, foot rest and horn.

Power Plant Includes 4-Cylinder Motor

The power plant is identical in the three models referred to, and includes the motor, which has a 36.1 horsepower A. L. A. M. rating which is based upon four cylinders working 4-cycle with a bore of 4¾ inches and a stroke of 5¼ inches. The cylinders are T-type of special gray iron with the inlet valves located on the right-hand side and the outlet valve on the left. The cylinders are cast in pairs, are water-cooled, with a centrifugal type of pump for water circulation, the latter being driven by a gear which is meshed with a half-time system. The radiator is of the honeycomb type with sufficient surface not only to serve initially, but taking into account the deteriorating influence of time. Lubrication includes a mechanical oiler with a pressure feed and provision for adjusting and observing the flow of lubricant. Carburetion is rather well cared for, utilizing a type of carbureter which has developed in this service; it belongs to the float-feed family with an auxiliary air valve which is, of course, brought into play at the higher range of speeds.

Ignition is of the make-and-break type, utilizing the Bosch magnetic plug system in conjunction with a Bosch low-tension magneto under hand control.

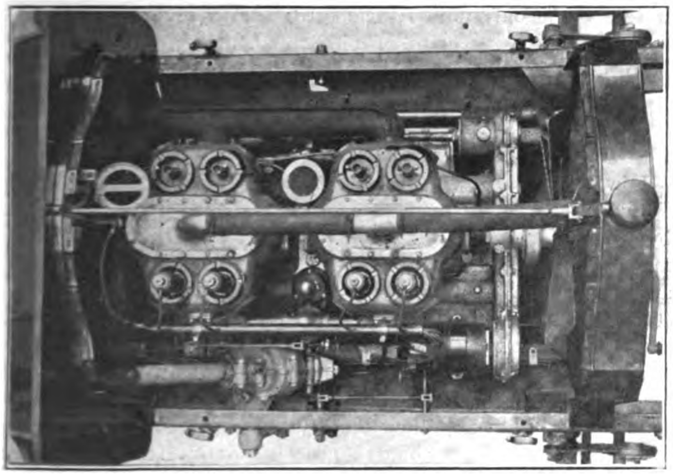
Besides the design features of the motor, which are further brought out by the illustrations here afforded, additional interest lies in the transmission system, taking advantage of a shaft-drive to a bevel gearset and a live rear axle of the full floating type. The power is taken from the motor by a cone clutch which is leather-faced with cork inserts, thence to a selective sliding gearset having four forward speeds and reverse with the distinction that the direct drive is on the third forward speed. This idea is liked by veteran tourists, because it assures that little extra increment of silence under all the normal conditions of road-going, and if perchance the sweet running qualities are slightly marred in the absence of the direct drive, it will only be at such enormously high speeds that the noise question ceases to be a factor, but with well-designed gears and the accuracy of workmanship which comes in a plant so wide in experience, it is not necessary to go into the direct drive to obtain a reasonably silent performance.



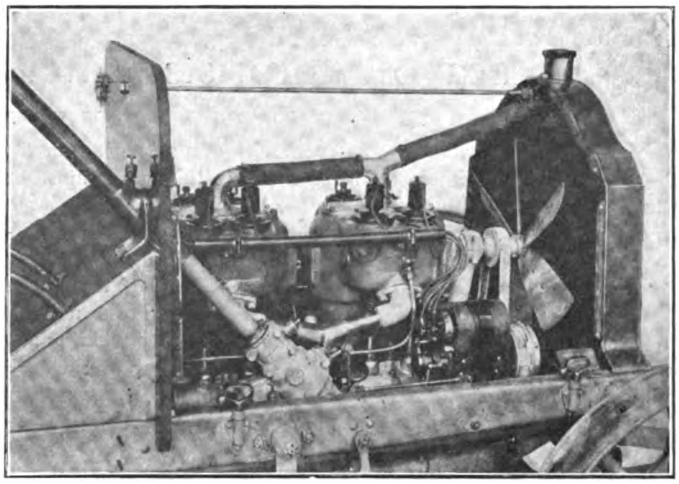
Rear of the chassis showing a stout cross member, support for the platform spring, method of shackling, upset chassis frame, and location of the muffler

Throughout the transmission system and the live rear axle annular-type ball bearings of properly sized selections are employed, notably among which will be found a thrust bearing for the clutch. The gearset, including the main and lay shaft, are mounted on these annular-type ball bearings, and the rear axle, including the floating of a differential housing passing through the front wheels, they, too, have these annular ball bearings, and, unusual as it may seem, they are extended to the steering gear. Parsons white bronze is used in the few places where it is not considered advisable to depart from conservative engineering to the extent of adopting ball bearings, as in the crankshaft, camshaft and clutch sleeve.

The fact that the car is heavily powered rendered it necessary to look well to the control system, to employ good materials in the control parts, and to so design that the application of pressure would be directly transmitted with substantial freedom from lost motion and the assurance that a pound of pressure applied to a pedal would be multiplied to the desired extent, making the pressure on the brakeshoe faces, for illustration, sufficient to skid the road wheels should the occasion require. The emergency brakes are under the guidance of a side lever; they are of the internal expanding type. The service brakes, however, are constricting, and are under the command of a pedal.



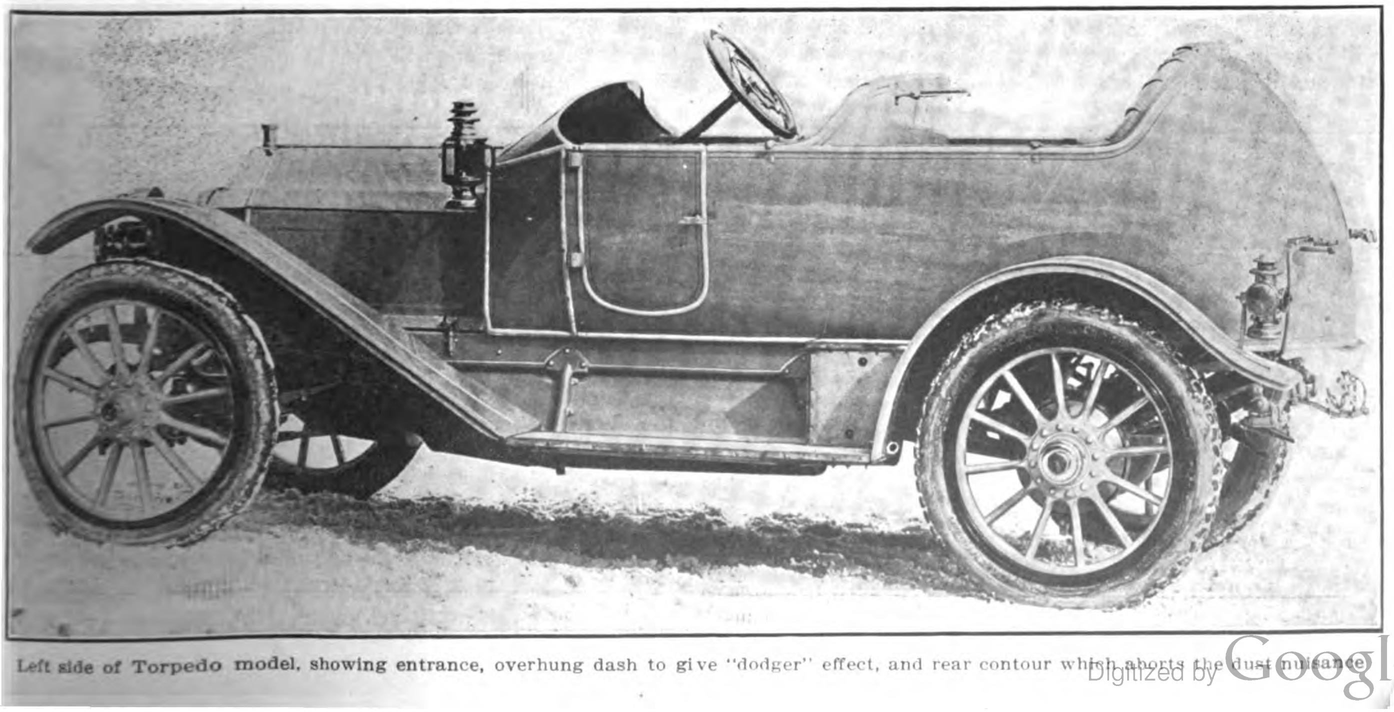
Plan of the motor depicting the relations of accessories, water connections, spark plugs, and other details



Right side of the 4-cylinder motor showing the location of the magneto, carbureter, and details

Among the details which are worked out to a fitting conclusion is the steering gear of the worm-and-sector type with F. & S. thrust-bearings, flanking the worm at either extremity, and methods of design, which induce accuracy in the machining process, together with means of heat treatment to assure a glass-hard surface of the work, and such accuracy of the jigged housing that lost motion is eliminated, not only initially, but on a permanent basis. The steering wheel is of large diameter, and mahogany rim is built up on the flanging of a substantial dished spider, which in turn is fetched up on a taper and keyed to the steering post. The spark and throttle control are by means of nice-appearing levers on the top of the steering post, the motions of which are interpreted by bevel sectors meshing with pinions at the lower extremity of the wheel. The linkages between the steering wheel and the swiveling members of the front wheels are of substantial design with liberal bearings, means for keeping out silt, and devices for maintaining a proper state of lubrication. In many other ways throughout the car these same refinements in engineering detail are fittingly cared for, and grease cups abound at every point at which a squeak could creep in in the absence of lubrication.

The wheelbase is 117 1-2 inches with a tread of 54 inches, and the tire equipment is 36 x 4 front and 36 x 4 1-2 rear. The front spring suspension is semi-elliptic, but the half-platform idea holds sway in the rear. The materials used throughout the car are in accord with the present-day idea of quality, carried to far greater length perhaps in some cases. As per illustration, the I-section front axle is die-forged in one piece from a selected grade of nickel steel.



Left side of Torpedo model, showing entrance, overhung dash to give "dodger" effect, and rear contour which aborts the dust nuisance

Chicago Motorists Entertain 1500 Orphan Children

CHICAGO, July 16.—Almost every city of prominence in the country has remembered the orphans this year—most of them during the month of June—but it has remained for Chicago to wait for settled and warm weather before showing its charity toward the youngsters. Here the weather generally is raw in June, so the Chicago Motor Club, Chicago Automobile Club and Chicago Automobile Trade Association did nothing in this line until last Thursday, when the combination pulled off the most successful orphans' day in the history of the city, taking 1,500 children in 160 cars for a pleasant drive around the boulevard system—a ride of some 35 miles which was thoroughly enjoyed by the kids.

In a way Chicago's efforts differed from those of other big cities. It was believed the children would enjoy a long ride rather than to be taken to some amusement park and, acting on this theory, the joint committee from the three organizations, George T. Briggs, John H. Kelly and Joseph F. Gunther, started a campaign for cars. They didn't have much time in which to work and up to within a few days of the run it looked as if it would be impossible to get enough machines for all the children. It was felt that it would be better to call it off rather than leave even a single child behind, so the efforts of the committee were redoubled. Prominent citizens were called up by telephone, the row was raked with a fine-toothed comb, and at the eleventh hour it was reckoned there would be enough cars to visit the fourteen institutions that had been invited to participate.

That the charity appeals to all was shown by the fact that of the 160 cars in line more than 100 had been contributed by private owners. Society women became enthused and noticed in line were several electric runabouts. True, they could not carry many children, but their owners were doing the best they could to help and their mite was appreciated. It also was noticed that there were few high-priced cars in line and it was discovered that there exists in Chicago many a rich man who would not help simply because he was afraid the children might scratch the paint in the tonneau. There were exceptions to this rule, of course, and some of the big cars that were out were packed to the limit, even to having a row of small boys perched on the tops, which were lowered for the purpose of making more room. Extremes meet, they say, and so it was in this case, for in sharp contrast to the big machines was one old one-cylinder car with a detachable tonneau, whose owner was carrying as many boys as he could and apparently he was delighted with his experience. Several women drove their own gasoline cars and in addition there were several big trucks.

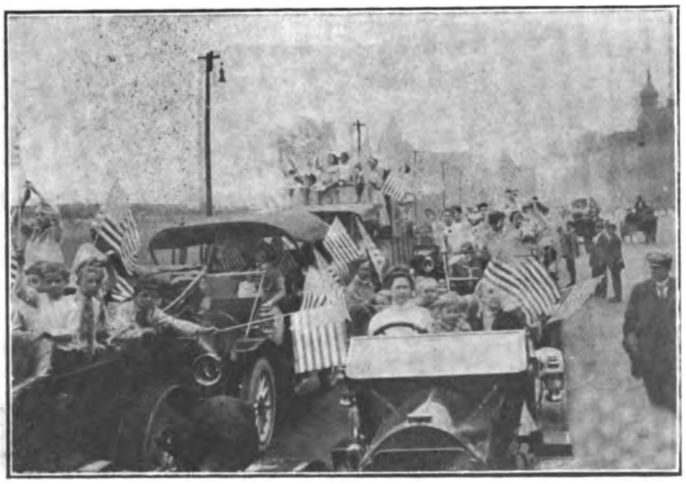
The Saurer truck carried fifty children and made an imposing appearance. The Chicago *Tribune* and the Chicago *Examiner* each sent out trucks which were filled with young humanity, while a White gasoline truck whizzed along with at least twenty-five kids aboard. The motor-cycle police were on the job and were of great assistance in keeping the cars in line and preventing scorching. Indeed, the marshals frowned down on any exhibitions of beating it and one driver was placed under arrest for endangering the orphans.

The ride was not the only feature of the afternoon. The committee had provided something else to delight the kids, distributing packages of peanuts and candy and also handing out more than 1,000 flags. While the outing was to consist only of the ride, there were many who stopped at the refectories in the south side parks and bought cake and ice cream for their charges. Toward the end of the ride there was a slight shower, but this did not detract from the joy of the kids. The orphans were not the only ones remembered, for in several of the cars were fifty from the homes for the aged, there being three institutions sending their people.

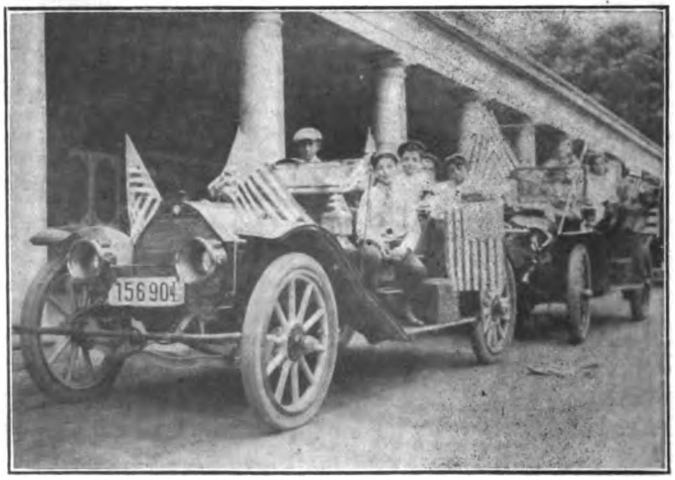
Lowell Aldermen Favor Road Race

LOWELL, MASS., July 18—At the last meeting of the Lowell Board of Aldermen action was taken on the petition presented by John O. Heinze, asking that the roads comprising the Merrimac Valley race course be closed to the public September 15, 16 and 17, and after a lengthy hearing the petition was granted. There was a counter-petition presented by Thomas A. Larkin, an attorney representing 22 residents of Varnum avenue, opposing the races, and a petition signed by a number of business firms asking that the part of Mr. Heinze's petition to close the roads on Saturday be denied. When those in favor of the petition were asked to stand to be counted nearly everyone in the chamber got up, and Mr. Larkin was the sole one to stand when those opposed were called. So the board granted the petition unanimously.

Mr. Larkin suggested that the matter might be taken to the courts by seeking an injunction. This was tried last year without avail. Mr. Heinze will appear this week before the Selectmen of Tyngsboro with another petition asking their authority to close such portions of the road as go through that town. As the Selectmen favored the petition when it was presented to the Legislature, no opposition is expected there. Two races are planned now, one for small cars, September 15, and another for big cars, September 17.



Start of the Chicago Orphans' Day outing



Many of the parentless "kids" stop at refectory for ice cream

Studies in Aviation Theory and Practice

By MARIUS C. KRARUP

(Continued from last week.)

REFERRING to Fig. 4 C, if the machine is advancing and the wings opposite to the side where the disturbance comes from reach the horizontal position, as shown in dotted lines, the counter-balancing support derived from them will be at its maximum, and on the whole the lateral stability in this type is therefore improved. But in normal flight the sloping wings do not support quite as well as the horizontal ones, and within a small angle they are more sensitive to a side wind than horizontal wings, offering a tilt aggravating the first attack, and this is especially the case because most winds are nearly horizontal. The lateral safety or stability of the aeroplane built with a strong dihedral angle, as compared with other aeroplanes, is most pronounced, it seems, in cases of extreme disturbance, as represented in the last figure of C. In any of these types the fore-and-aft stability seems to depend almost entirely upon speed and tilt rudders, which means that it is not automatic or dependable under all conditions. The most obvious means for producing stability of this description are apparently a low center of gravity well to the front, to prevent a backward tumble, and elastic rear edges for the wings of the main plane or planes, which will automatically counteract any disturbance by the wind tending to produce a headlong plunge.

Summarizing, the monoplane type has the best lateral balance, but it is difficult to build with enough surface to permit operation at small tilts, and the small tilt for normal travel alone gives range for up-and-down control (since tilt changes cease to be efficient above 15 degrees). With speed, a center of gravity placed forward of the center of a plan projection of areas can be supported, and without speed it produces automatically a gliding tilt, which is wanted when speed has ceased. Yielding rear edges give stability against forward plunging. The center of gravity may be lower than customary, if control is rendered positive by changing from rudder action by means of outlying surfaces to a system of relative mobility of the main supporting areas. Outlying control surfaces, being subject to the wind's attacks, themselves reduce stability. Planes of the highest carrying capacity per square foot increase stability by reducing wind-catching areas.

But the worst enemy of stability is any supporting plane which is located lower than the center of gravity, or on a level with it, and which is nearly horizontal in the normal position of the machine and concave downwardly, so that a change of its angle under an upsetting influence tends to produce a further change by increasing the efficiency of the disturbing wind action. This speaks for a design in which the monoplane's scant supporting area is helped out by lower supporting areas, but the latter formed with slightly convex surfaces (or the equivalent thereof) which are self-righting instead of self-upsetting. How much there should be of such lower surfaces must be a matter for experimental decision. A type intermediate between monoplane and biplane seems to be indicated as promising.

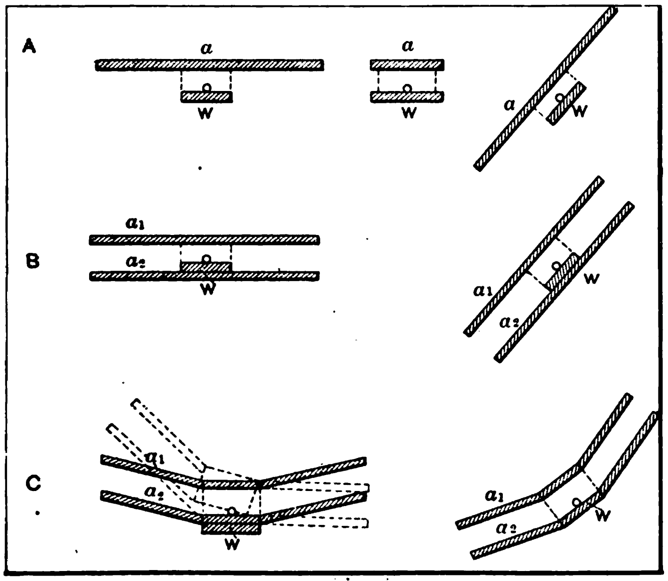


Fig. 4—Illustrating various phases of lateral stability

In several places trials are being made of boat-shaped substructures for monoplanes, and these should have a value for stability if proportioned closely in accordance with the areas and distribution of available superior surfaces and the strength of the propulsive power, because the double convexity of the boat shape—speaking of boats like the Norwegian or Malacca yawl—acts as a dihedral angle, roughly speaking, both laterally and fore-and-aft. But it is evident that the relatively feeble sustenance derived from convex surfaces in conjunction with the relatively high resistance against their propulsion should bring into play a very nicely balanced judgment on the designer's part in limiting the tangential angles of the convexity and the areas of the structures referred to. From the published reports with regard to them they seem to represent something less valuable. In some cases their designers seem to be actuated by a vague idea about imitating the shape of a bird's body, while disregarding the fact that the bird's main supporting surfaces are adjustable with relation to that body, and the other important fact that the bird disposes over a very high propulsive power not yet equaled or approximated in the use of small high-speed propellers for aeroplanes. In other instances the object of the boat-like structure is simply to provide an arrangement for starting from water or alighting on water. In principle, however, the convex auxiliary surfaces, arranged to mask features in the construction which, if left in the open, would anyway create air resistance without assisting in propulsion, seem to offer a fruitful field for investigation.

To increase fore-and-aft stability, there remains another possibility. With plane or planes extending at right angles with a vertical plane through the axis of the machine, the centers of sustentation-pressure form a line which shifts forward and backward with the speed of the machine, with a decrease and increase of tilt and therefore with changes in the load. By raking the wings of the plane rearward from the middle, so that their rigid front edges form a <, a broader support would be gained, and shifts of the centers of pressure due to accidental causes would require less counteracting by control movements; that is, the automatic stability would be improved, and the resistance to propulsion reduced.

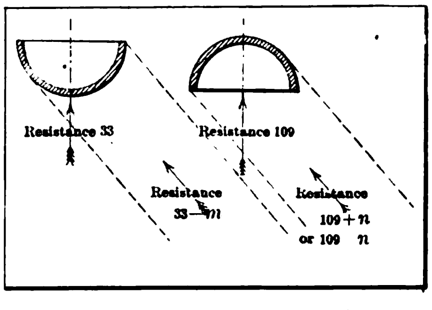

Fig. 3—Illustrating importance of shapes for stability

Automatic stability, being manifestly a product of many minor factors, each of which must be tried out quantitatively, is not likely to be gained in full measure except by the slow steps of an evolution. The designer's efforts for attaining as much of automatic stability as is consistent with facile control should be supplemented with equal efforts for reinforcing and improving the control of the machine's equilibrium and direction.

Some Points Worth Knowing About Automobile Gasoline

FUEL for internal combustion motors in liquid form is called "gasoline," which, in the old days, meant a certain distillate having a certain specific gravity, a certain value in the scale of volatilities, and its other characteristics were definitely established and generally understood by those who give matters of this sort passing notice. The coming of the automobile brought about many changes, it being true that the gasoline which was once rated as a by-product and a drug on the market mounted to the position of the fraction of first importance, and all the other distillates of crude oil were relegated to the rear, many of them reaching the low level which is normally designated as by-product. In coping with this problem, the distillers of crude oil began by tampering with the original gasoline, widening the range of temperatures used in the distilling effort, thus adding to the number of the contents, until finally the words "Automobile Gasoline" were coined to meet the occasion. That which was true of gasoline *per se* no longer obtained, since dealing with composite fuel was not the same as when dealing with a single closely confined distillate. The old idea, for instance, of sticking a hydrometer in the can to determine the specific gravity of the gasoline ceased to be valuable in the newer work since hydrometers are not made to determine the specific gravity of a plurality of distillates simultaneously. The only way to utilize the hydrometer advantageously will be to first separate the distillates, and then measure each one of them separately. These indications of the problems involved in the handling of automobile gasoline are but a few of the many which will have to be taken into account in a comprehensive estimate of its value, which, however, will only be possible if it is fully appreciated that the automobile gasoline of the day bears but slight relation to gasoline as it is technically designated.

Temperature of Change of State of Aggregation

Water boils at 212 degrees Fahrenheit, under a pressure of one atmosphere. As long as any water remains in the pot, no matter how hard the fire is urged, the temperature will remain constant until all the water boils off. The only way that steam can be superheated is to take it from the presence of water. The reason for calling attention to these well-known phenomena is in order to bring out the facts in relation to gasoline on a basis which will permit the average reader to grasp the situation. Gasoline, like water, must be changed in its state of aggregation from liquid to gas; in other words, it must be boiled, and the temperature of boiling of the gasoline must obtain in order to bring about the requisite heat exchange. Gasoline boils, of course, at a far lower temperature than water. Since it is a composite mixture, the temperature of boiling of the respective distillates are different, and in the ordinary process the more volatile of the distillates boil off first, leaving the heavier portion for the last, and the minimum temperature of boiling of the respective components is as follows:

MINIMUM TEMPERATURE OF EVAPORATION

Hexane	Heptane	Octane	Decane
17.7	3.6	19	42

As will be seen, hexane boils (evaporates) at a very low temperature. Referring to decane, however, the boiling point is 42 degrees above the freezing point of water, *i. e.*, 42 degrees Centigrade.

Heat of Evaporation Must Come Out of the Air

In the ordinary carbureter the gasoline is sucked out of the nozzle by the difference between the depression surrounding the nozzle and the atmospheric air. The spouting gasoline is more or less reduced to a cluster of multi-sized globules, the smaller of which form a sheet around the main stream in sufficiently fine subdivisions to be called a spray or mist; that there is very much mist is doubted, and one of the principal difficulties in carburetion is to obtain the minuteness of atomizing, which will permit of the quick transfer of heat from the inrushing air to the body of liquid gasoline, in order that the same may be boiled just as water is in a pot when a fire is put under the same. In the case of the pot and the water, the heat comes from the combusted fuel, and is transferred through the wall of the pot to the water to be boiled. Sometimes, however, water is boiled by directing a stream of steam into the body of same. In the case of the carbureter, a stream of air carrying heat is mingled with the stream of gasoline molecules and the excess heat in the air over that in the gasoline is transferred to the latter, and it, too, is vaporized as fast as the heat is transferred in quantity sufficient to counteract the latent heat of evaporation of the gasoline.

Minimum Temperature of Air, Considering Specific Heat

Just as the values for latent heat dispose of the question of the number of heat units required to vaporize the gasoline, so does the specific heat of air on the one hand, and of liquid gasoline on the other, afford a means of determining the minimum temperature of the air for a given temperature change. This minimum temperature is not the same for all the gasoline contents, and the table as follows tells the difference which must be observed, considering the respective distillates:

MINIMUM TEMPERATURE OF AIR FOR DIFFERENT DISTILLATES

Hexane	Heptane	Octane	Decane
1.3	21.5	36.2	56.8

These temperatures are on the assumption that no heat will be transferred to the gasoline, excepting out of the air; in other words, there must be enough heat available in the air at the minimum temperature in degrees Centigrade as above given to furnish the latent heat of evaporation, and the basis of arriving at this fact takes into account the specific heat of the gasoline and the specific heat of air. The latent heat of evaporation of gasoline cannot be stated with certainty without first ascertaining the exact proportions of the distillates. It may be approximately stated for a good grade of automobile gasoline as 210.5 British thermal units. The specific heat, or amount of heat required to raise 1 pound of gasoline 1 degree Fahrenheit is 0.500. In other words, a drop of 1 degree Fahrenheit in the temperature of 1 pound of gasoline corresponds to a dissipation of 0.5 British thermal units of heat. The specific heat of air at a constant pressure of 0.2375, and a drop of 1 degree Fahrenheit is therefore attended when 0.2375 British thermal units of heat are transferred from the air to the gasoline. If the temperature of the air is not below the minimum, as here stated, considering the respective contents, this condition will be brought about.

The Influence on Efficiency of Combustion

The highest obtainable thermal efficiency in an automobile type of motor (working 4-cycle) seems to be about 20 per cent. While it is true that the larger part of the 80 per cent. inefficiency is due to absorption of heat to the water jacket, and to heat carried away in the exhaust, the fact remains that combustion is more or less incomplete, and some of the thermal loss is directly traced to this point. With complete combustion, the products would be as follows:

PRODUCTS OF COMBUSTION PER POUND OF GASOLINE

Carbon Dioxide	Water Vapor	Nitrogen
2 pounds	1 1-2 pounds	11.8 pounds

The above result is obtained through the use of 15.3 pounds of air per pound of gasoline, assuming that the gasoline is completely vaporized and that it is burned to finality. What really happens in the average motor is that the intermingling of the air with the gasoline is more or less imperfect, and the exhaust, instead of being as above indicated, holds a certain amount of carbon monoxide and hydrogen. The loss due to these causes may be directly estimated by determining the percentage by weight of the carbon monoxide and the hydrogen present in the exhaust, and by considering their fuel value in connection with the fuel value of the original quantity of gasoline.

An Excess of Atmospheric Air Is Necessary in the Mixture

Owing to the presence of products of combustion—in other words, to incomplete scavenging of the motor cylinders—it is impossible to arrive at anything like complete combustion when the quantity of air present is the theoretically correct amount. To overcome this difficulty it is customary to utilize an excess of air, and it is not uncommon to use as much as 60 per cent. excess over and above the theoretical right amount necessary for the complete combustion of the fuel.

The exact proportion of excess of air is not to be stated as a fixed value; it depends upon the compression. The higher the compression in the cylinder of a motor the higher must be the excess of air to afford complete combustion. One reason for this lies in the fact that the rate of flame travel is increased with increasing compression, and the allowance of time for the absorption of heat, and the contact of the molecules of hydrogen and carbon with oxygen is reduced. A second reason may be directly traced to the great difficulty of scavenging with the increase in speed of the motor, which is likely to follow when the compression is increased, so that one complication adds another, and it has been found in practice that the increase of air over and above the theoretical right amount is progressive rather than proportional to the relating factors. That there can be too much air is, of course, well understood.

The Enriching of Automobile Fuel

By JAMES S. MADISON

A discussion of the difficulties following the introduction of foreign substances into a motor's cylinders in the gasoline passing through the carbureter, and the methods by which greater power may be secured from a given quantity of gasoline.

SINCE the building of the first automobile every part of it has been subjected to the most careful and exacting study, with the hope of introducing improvements. The results show a marvelous development. After it had been demonstrated that the automobile had become a permanent factor in our industrial and social activities, a tremendous amount of time and study was spent in endeavoring to improve the available power of the engine. This led to a detailed and exhaustive examination of the ignition and carburetion systems—more especially the latter—of the compression pressures, of the size and timing of the valves, etc. When these important factors had been standardized many attempts were made to generate still more power by enriching the fuel—that is, by adding certain substances to it which would cause it to ignite more readily, or, being ignited, to burn more rapidly. That such attempts have not been generally successful, and in many cases have shown results that were undesirable is probably, in a large measure, due to a lack of understanding of the elementary principles involved in the operation of a gas engine, or to what may be called the experimental difficulties necessarily inherent in the attempt to introduce foreign substances into the cylinders through the medium of the gasoline passing through the carbureter. It is the object of this article to discuss these elementary principles as simply as possible, the methods that have been used for enriching, and to point out one method by which greater power may be secured from a given quantity of gasoline.

For the purpose of discussion, let it be assumed that the piston of one cylinder of an automobile or other internal combustion engine has just completed its suction stroke, by which it has drawn into the cylinder its charge of the mixture, composed of air and of gasoline in the form of vapor, which is a transparent, invisible gas, like the air we breathe, and which will burn, if it be supplied with the proper amount of oxygen and ignited. It is the function of the carbureter to supply to every particle of gasoline (in the form of a vapor or gas) that enters the cylinder the proper amount of oxygen for its complete combustion or burning, by admitting the correct amount of air, one-fifth of which is oxygen and four-fifths nitrogen. Assuming, further, that the carbureter is performing its function normally, there is in the cylinder a combustible mixture, or in common terms, one that will burn. If the carbureter admits too little air the mixture becomes too "rich," and will burn incompletely, or not at all; or, if too much air, the mixture becomes "lean," and will give equally unsatisfactory results; hence the necessity for adjusting the carbureter until it gives a mixture containing exactly the right proportion of air and gasoline vapor. If now an electric spark be passed between the points of the spark-plug, which projects into the cylinder and is surrounded by the mixture, it acts precisely like a match, the mixture is ignited, and burns so rapidly that a sheet of flame shoots from one end of the cylinder to the other. This is commonly called the explosion, and happens hundreds of time per minute when the engine is running rapidly. The burning of combustion has caused the formation of at least two new substances (there may be more under certain conditions, and usually are, but a reference to two will be sufficient for the present purpose) from the mixture of air and gasoline vapor; one of them is water vapor, or steam, and the other is the gas, carbon dioxide; in addition to these there is present in the cylinder the gas nitrogen which, as stated above, is a constituent of the air, and which was drawn into the cylinder with the charge. These three substances, and any others that may be present, under the influence of the intense temperature of the flame expand enormously—there is an enormous increase in their volumes—which produces a great internal pressure on the cylinder walls and piston head; since the latter is the only moving part, it receives from the expanding gases a tremendous impulse, which results in what is called the power stroke, the motion of the piston is communicated by means of the transmission and drive shaft or chain, as the case may be, to the rear axle. It thus appears that the motion of the road wheels is due to the burning, or combustion, taking place in the cylinder. The impulse imparted to the piston by the suddenly expanding gases, causing it to move, is the same kind of an impulse that is imparted to the projectile in a rifle.

One reason why the burning is not more rapid and the impulse transmitted to the piston not more powerful is that for every part of oxygen drawn into the cylinder four parts of nitrogen are also drawn in. This nitrogen is not only useless in increasing the effects of the burning, but, on the contrary, it is a positive deterrent, since it dilutes the oxygen to such an extent as to neutralize much of its desirable effect. If the proportion of the nitrogen could be reduced, the burning would be correspondingly more rapid with the consequent more rapid expansion of the gases formed, which would result in more powerful impulses being delivered to the piston. One method of reducing the proportion of nitrogen is to increase the proportion of oxygen. This has been done many times by mixing certain substances with the gasoline. A substance, to be of value in this connection, should have the following properties: it must contain a fair proportion of available oxygen; it must decompose readily into its constituents; it must be soluble in gasoline; when burned in a closed space it must not leave a liquid or solid residue, and the products formed by burning it must have no injurious action on metal.

Letters Interesting, Answered and Discussed

Discussing burning qualities of gasoline; the principles of magnetos; causes of wobbling of front wheels; electric lighting; qualities for racing drivers; automatic stability in aeroplanes.

May Be Slow Burning

Editor The Automobile:

(2,333)—I have a garage made of wood within 10 feet of the wooden dwelling in which I live, and while I have no trouble getting insurance, the fact remains that I worry about the fire risk, and wonder if the insurance will be hard to collect in case the house burns down due to a fire resulting from the presence of gasoline in the garage. Can you set my mind at rest?

G. J. M.

Evansville, Ind.

Call upon the Board of Fire Underwriters and see if the rules are being violated by having a garage within 10 feet of a dwelling house. If so, move the garage far enough away to conform to the rules. Rules are formulated for reasons that are probably good, and to follow them is a necessity if you wish to be sure that you will not be held responsible for their violation. In the meantime, gasoline in liquid form in a tank is non-inflammable, due to the fact that oxygen cannot mix with it in its liquid state, but even if oxygen were dissolved in the liquid up to the limit of saturation it would still be non-inflammable. The only way gasoline can be burned is by changing it to a gas in the presence of oxygen, and even then it resists burning to some extent. Fig. 1 is a simple illustration of the non-burning qualities of gasoline. It shows a torch which is lighted, and so adjusted that the flow of gasoline is at a high rate. The excess gasoline splashes against the plate shown, and trickles down over the surfaces to the ground without burning. The particular part of the gasoline that burns is hexane, of which there is only a small portion present; the volatility of the rest of the gasoline is relatively slow, and it fails to burn under the conditions shown, because it resists the gasifying process, and as before stated, it will not burn until it is gasified.

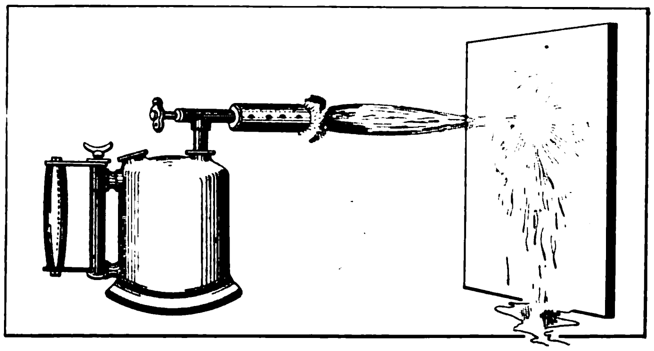

Fig. 1—A lighted gasoline torch blowing the burning liquid against a sheet of tin, burning the hexane, and the heavier distillates, after splashing against the plate, trickle down to the ground.

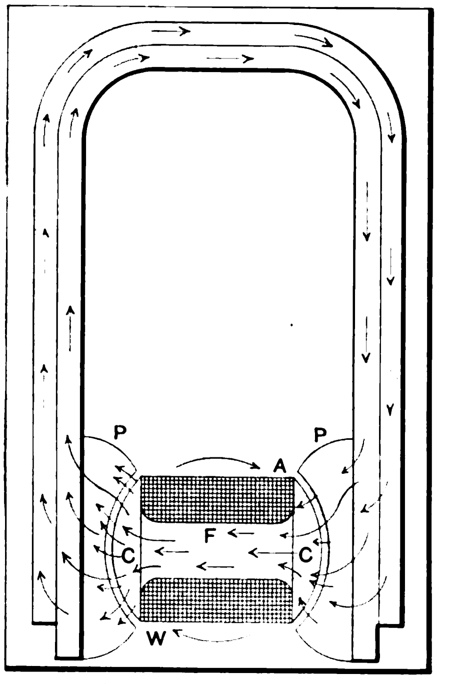

Fig. 2—Characteristic diagram of a magneto with a single winding on the armature showing the closed magnetic circuit

If the tanks containing the gasoline are not tight, it will evaporate even at normal temperature and form a combustible mixture with the oxygen of the atmosphere, which will ignite upon contact with a flame.

Some Questions in Relation to Magnetos

Editor The Automobile:

(2,334)—When I look at a magneto as it is installed in an automobile, I see so many trinkets hanging thereon, and find it nested among so many other things, that, in view of my lack of experience I become confused, and yet I realize that a man who drives an automobile ought to understand the A B C of the situation, and I appeal to you in my helplessness, hoping, perchance, that you will be able to separate out a few of the essential particulars and illustrate them in your customary clear fashion for my benefit, but I think I may say that I am not alone in this wilderness of confusion, so that your audience will scarcely be limited to one subscriber.

Perplexed.

Camden, N. J.

You can scarcely expect to obtain all the information you want outside the two covers of a "fat book." In the meantime, if the ignition situation is separated into its components, the respective divisions may be studied with some hope of eliminating confusion. There are three types of magnetos in vogue, (a) low-tension, (b) high-tension, and (c) combination magnetos. All magnetos, of whatever system, are composed of a wire-wound armature and a permanent magnetic field. As a rule, the armature rotates and the lines of force, which reside in the permanent magnetic field circulate through the rotating armature as shown in Fig. 2, the arrows indicating the direction of flow of the magnetic flux, and when the armature rotates, the lines are throttled as shown in Fig. 3. The variation in the magnetic flux, as indicated between Figs. 2 and 3, is responsible for the induced current which is set up in the wire windings on the armature, which current is the product of the difference of potential which results from a change in the intensity of the magnetism. The windings do not have to be on the armature, and Fig. 4 shows a type of magneto which has its windings on the soft polar members to which the permanent magnets are attached. In this case the intensity of

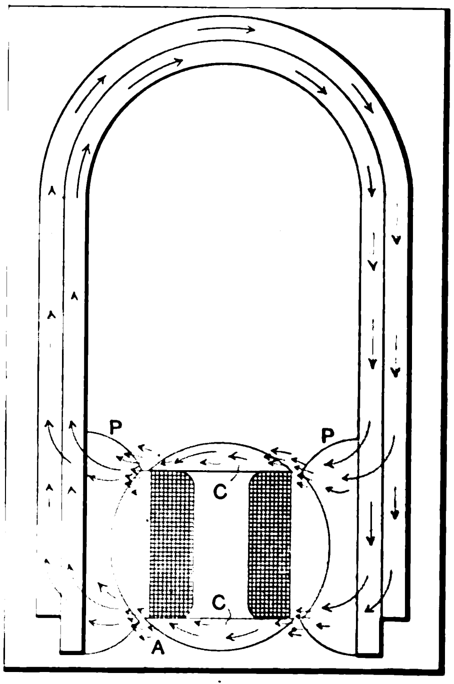

Fig 3—The same as Fig. 2, with the exception that the armature is rotated 90 degrees and the circuit is interrupted

the magnetic field is varied through the revolution of the rotor A, which has radially disposed extensions, and the path of the magnet field is interrupted periodically. Still another form of magneto is given in Fig. 5. In this case, the armature is stationary, the windings W being over a fixed body. The permanent magnets are bolted to soft polar horns, and a shell-like rotor occupies the space between the polar faces of the wire wound bobbin and the soft polar horns of the permanent magnets. Here again, the rotor is responsible for variations in the magnetic field brought about by periodically interrupting the continuity of the magnetic circuit. Fig. 6 is offered in order to bring out the point to be made in relation to the "condenser," which is always used in conjunction with ignition systems. In this example, the magnetic field comprises permanent magnets F, G and H with soft polar horns BB bolted thereto, and the bobbin wound rotor A, the windings showing at D, but the condenser E is housed in a rectangular aperture within the bobbin. The condenser is made up of flat sheets of tinfoil insulated from each other, and connected up in parallel. The difference between a high and low-tension magneto, barring a few details in connections and arrangement, is confined to the winding on the rotor. If there is only one winding of coarse wire, it is a low-tension magneto, but if there are two windings, one of coarse wire and the other fine, a high-tension magneto results. The composite arrangement is made up of a low tension winding on the rotor of the magneto, which connects to an ordinary spark coil which may be located on the magneto or elsewhere. The voltage of a low tension magneto is too low to jump the gap in a spark plug, so they use a wipe spark system, which is so arranged that the circuit is first made by a hammer striking an anvil and when the hammer bounces off of the anvil, the arc is drawn, and the mixture in the cylinder is ignited. With the high-tension system, the voltage is about 20 times that of the low, and the spark gap in the plugs is broken down at the right instant, thus inflaming the mixture. There are many other points in detail which ought to be looked into by an inexperienced autoist, but there is no reason why confusion should result. All of the items to be mastered are quite simple, and by taking them one at a time, just as one must do in acquiring a knowledge of the French tongue, for instance, the progress that can be made in a short while is astounding.

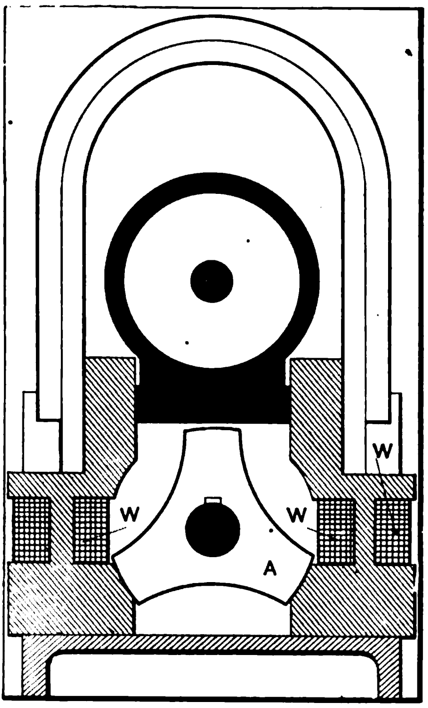

Fig. 4—Type of magneto using a rotor to interrupt the magnetic circuit, but the windings are on soft polar members to which the permanent magnets are bolted

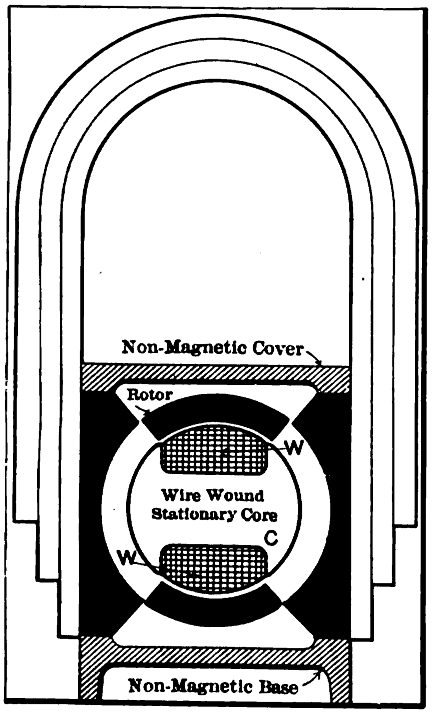

Fig. 5—Type of magneto using a shell rotor, permanent magnets bolted to soft polar horns, and fixed armature of bobbin-like design on which windings are placed

Wrong Design or Worn Out

Editor The Automobile:

(2,335)—I have never seen anything in your valuable paper in reference to the front wheels of an automobile wobbling. I am troubled this way, and perhaps others are, so an answer in your "Letters Interesting" would perhaps help a number of your subscribers. I am annoyed by my front wheels wobbling when going over rough places, and I understand some French cars do the same: I have gone over all the parts and joints and they are all absolutely without play; they are all ball and socket type, so can be adjusted perfectly. The only looseness is in the steering gear proper. When running fast or on smooth roads the wheels do not wobble. Any advice you can give me will be appreciated. W. W. Trevor.

Lockport, N. Y.

One cause of wobbling of the front wheels is assignable to short steering knuckle arms. This difficulty is rarely present in automobiles, it being the case that most designers realize that the steering knuckle arms should be quite long so that the steering action should be quite "slow." Lost motion is, of course, a prominent cause of front wheels' eccentricities. The way to overcome this trouble is to have the automobile repaired.

Electric Lighting Has Many Advantages

Editor The Automobile:

(2,336)—Will you please advise me in your question and answer column whether you consider it worth while to replace acetylene lights with electric lights. I can appreciate that it would be a great luxury to be able to turn the lights on or off by pressing a button, but I believe that storage batteries would soon be discharged, and do not want the bother of taking them off the car to be recharged. I would like to have a complete lighting plant on my car.

A. E. W.

New York City.

If you can afford to install an electric lighting system it will serve you well, and add to the pleasure of touring. If you keep your acetylene system in order, it, too, will be your faithful slave.

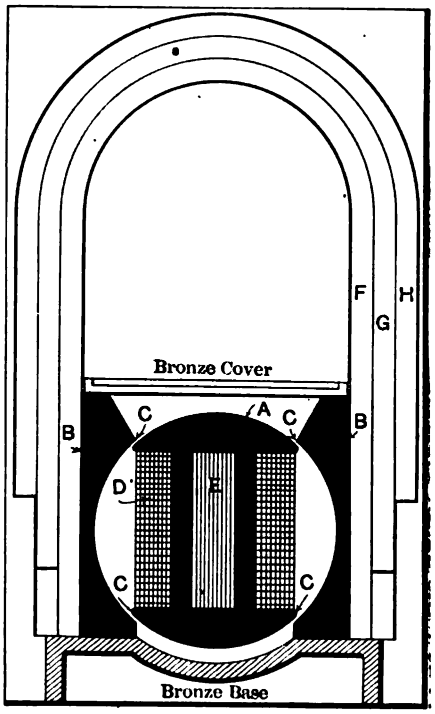

Fig. 6—Type of magneto using a bobbin wire-wound armature, soft polar horns to which the permanent magnets are bolted with the condenser within the armature

Questions That Arise—General In Scope

Discussing ills of mufflers; proper methods of suspending mufflers; advantages and disadvantages of the several shapes of pistons; main points in relation to valve springs; manner of contriving valve motions so that timing can be varied at will.

(178)—Is silence of a muffler attended by increased pumping losses of the motor?

Not necessarily; but, as a rule, silence is attended by back pressure, and the pumping losses are augmented in consequence. Fig. 1 shows a conventional type of muffler which works on the obstruction principle; the exhaust flows into the muffler through the exhaust pipe, and is split up by having to pass through a large number of small holes on its migration to the muffler chamber. This splitting process is at the expense of back pressure, and to whatever extent the obstruction suffered may be estimated in pounds per square inch as back pressure, it represents the measure of the deduction which must be made from the mean effective pressure before the same can be used in the formulæ for determining power. The gas after being split up by passing through the small holes as it enters the main chamber is scattered and it then oozes out through the orifice robbed of its ability to make a noise.

(179)—How should mufflers be suspended on the chassis frame, all things considered?

In view of the fact that mufflers are heated to a point sufficiently high to vaporize lubricating oil, they should not be placed in a position where lubricating oil can get at them, for then they will become a nuisance and serve as the basis for a violation of smoke ordinances. They should be flexibly mounted, and the piping leading from the motor should be so hung that its weight will not come on the muffler. The suspension shown in Fig. 3 is a fair illustration of a good way, but the exhaust pipe leading from the muffler to the atmosphere should not be pointed down as therein because the exuding exhaust will then brush against the roadbed, picking up dust, thus becoming the basis of a road nuisance. Fig. 2 shows the exhaust pipe to the atmosphere in the right position, but in this figure the muffler is not flexibly mounted, and it has the further disadvantage of having to carry the weight of the exhaust pipe and the additional fault of having the exhaust pipe in interference with the rear axle. As a final injunction, attention is called to the necessity of noiselessness, and this requisite is only to be consummated if the parts are all in secure relation and free from interference. A muffler cut-out serves no useful purpose whatever. It offers to a chauffeur wide opportunity to annoy the public at large, giving him a means of calling attention to his exalted position, and it is proof of the fact that the motor is not big enough for the work to be done, or that the back pressure of the muffler is greatly in excess of that which is dictated by good designing, unless it is attached as a matter of business expediency, with the idea that it will serve as a selling point, hoping to attract the notice of the budding autoist, who, unfamiliar with the technical situation, absorbs information from whatever source indiscriminately.

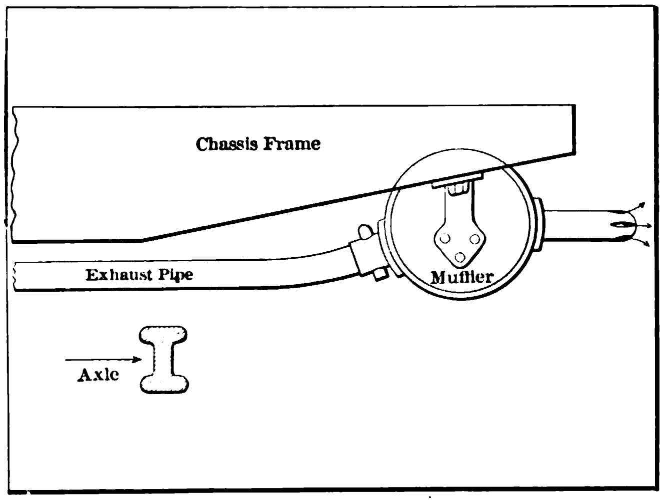

Fig. 2—Faulty method of suspending muffler, showing exhaust pipe in the right position

(180)—What are the advantages and disadvantages of the several shapes of pistons?

Referring to Fig. 4, A is a flat-head piston, B is of the convex-head type, C is spherical, and D represents the inverted sphere. Taking them in the order named, A, the flat-head type, offers no advantage, but it has the inherent defect which comes when a weight must be supported by a flat member, instead of an arch, has the further defect of not being a good shape from the foundry point of view, and when the internal strains are released, as they must be sooner or later, the head is likely to crack. B, with its convex head, which may have the form of a flattened ellipse, is regarded as the conventional type. It has the arched structure, which is capable of sustaining the greatest possible weight, and its shape is agreeable to foundry practice, so that the internal strains are relieved, and the chances of cracking in service are substantially eliminated. This form of head lends itself perfectly in designing; it permits of a spherical dome of the combustion chamber, and works out so that the compression of the motor will be substantially 75 pounds per square inch (absolute). Referring to C, of the spherical head, it has the disadvantage of offering too much surface, thus permitting a large amount of heat to pass through the wall and to the crankbox, hence decreasing the thermal efficiency of the motor and complicating the lubricating problem. But if there is no encouragement to be offered for the design C, the fact remains that it has many points in its favor as compared with the design D. All that has been said against C applies to D, but there is the further disadvantage in the latter in that it not only adds to the surface which will serve as a gate for the transfer of heat, but the metal of the head, where it joins the metal of the barrel, makes a bunching and a shrink hole is pretty nearly sure to be induced, if, indeed, there may not be a collection of them all around the rim.

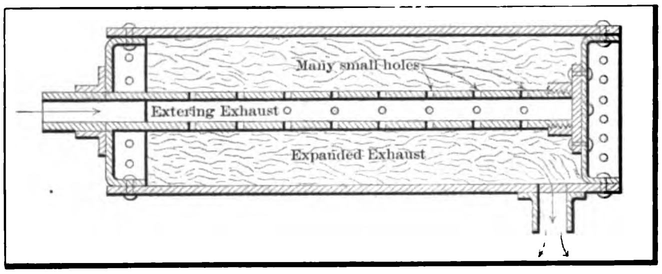

Fig. 1—Characteristic type of muffler which induces back pressure

(181)—What are the main points in relation to valve springs?

The wire should have the properties which come from the use of the best spring steel; there should be at least 10 turns of wire in the spring, as shown in Fig. 5, and the distance S should be so great that when the spring is compressed the respective turns will not contact with each other. The diameter of d of the wire should be so regulated that the diameter D of the coil will be sufficient to afford a live spring limiting the torsional moment to a point well within the elastic limit of the material so that the spring will remain substantially of constant strength from the beginning of its life to the ending of the life of the motor. This latter condition will only be possible if the spring is so placed that it will not be annealed by the heat which radiates from the motor cylinders. A table of the dimensions of various sizes of

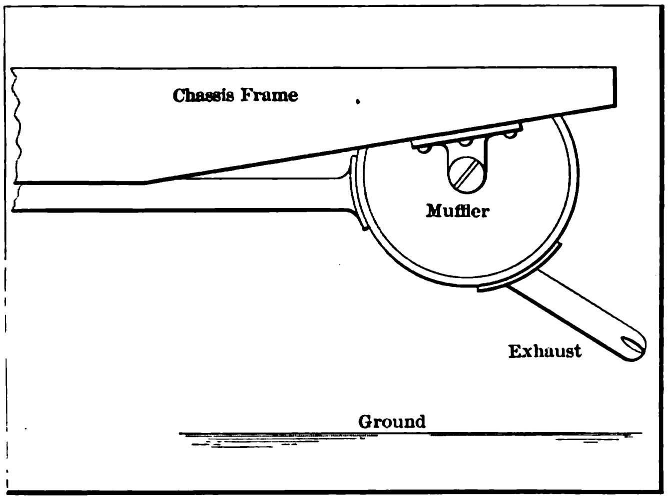

Fig. 3—Flexibly mounted muffler, showing the exhaust pipe in the wrong position

springs is given in Fig. 6. Knowing the weight in pounds which the springs must exert, it is possible to pick out sizes which will do the work.

(182)—Why is the "finish" so much restricted in cylinder designing, and why is it not a good idea to allow for several reborings?

The reason why it is necessary to re-bore a cylinder is because the wall surfaces are of uneven texture, and too soft to withstand continuous service under the severe conditions obtaining. Designers desiring, in the first place, to have the weight efficiency as high as possible take advantage of the fact that white metal is dense, hard, and strong. Gray iron, on the other hand, is soft and is likely to be of varying texture. White metal in a cylinder is induced by so regulating the charge that it will take on the property technically known as "chill." This "chill" is not to a great depth in good cylinder metal, so that in order to preserve the white metal surface the finish must be restricted. It will be remembered that all finished metal is machined off, and what is wanted in completed cylinders is just enough finish to permit of making a smooth bore without cutting through the white metal coating into the gray iron texture. Fig. 7 illustrates the situation with sufficient clearness, showing the chilled surface metal and the soft core.

(183)—Is there not some way of contriving valve motions so that timing can be varied at will?

There are several plans which include mechanical means for varying the timing of valves, one of the most interesting of which is shown in Fig. 8. In this case there is an auxiliary roller mounted on a boomerang which is pivoted at one end to an arm, the bearing of which is concentric with the camshaft. The boomerang, not being to unit radius, affords a means for varying the distance between the face of the cam and the roller proper on the valve lift. By rotating the boomerang arm the adjusting distance is changed at will, and the amount of adjustment may be fixed upon by changing the contour of the roller contact surface of the boomerang. This device is said to work extremely well, and while it offers some evidence of complication, the fact remains that the parts are stable and there is ample room in a motor for a device of this character.

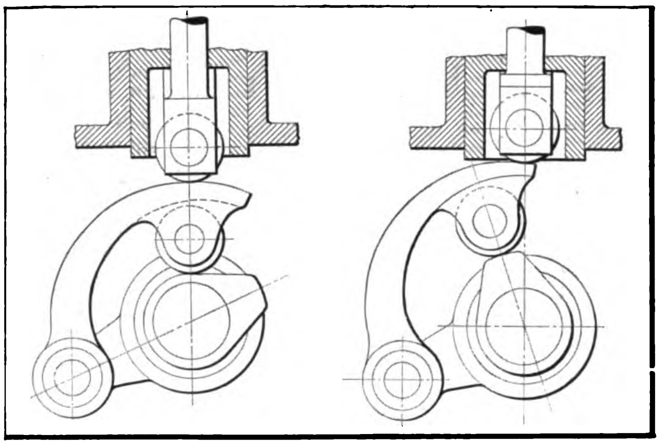

Fig. 8—Boomerang type of mechanism for use in timing valves

(184)—What are the troubles to be expected from timers?

It is difficult to predict; the best way is to test the particular timers and locate the troubles. The following test of a Herz timer should prove interesting.

The timer consists of a primary breaker and a high-tension distributor.

The timer was driven by a 5-horsepower shunt motor, using an Autocoil and a Gould 6-volt storage battery. Speed constant at 1200 r.p.m.

		Elapsed Time		
Started	Stopped	Hr.	Min.	Speed
10:20	12:05	1	45	1200
12:30	2:45	2	15	"
10:20	12:00	1	40	"
12:30	2:05	1	35	"
8:30	12:00	3	30	"
12:30	5:40	5	10	"
8:00	12:00	4	00	"
12:30	6:00	5	30	"
		25.4		

Therefore, the total number of revolutions =

$$25.4 \times 60 \times 1200 = 1,828,800.$$

The sparking was very irregular at 1200 unless the contact cam faces were wiped clean frequently. The highest speed for good

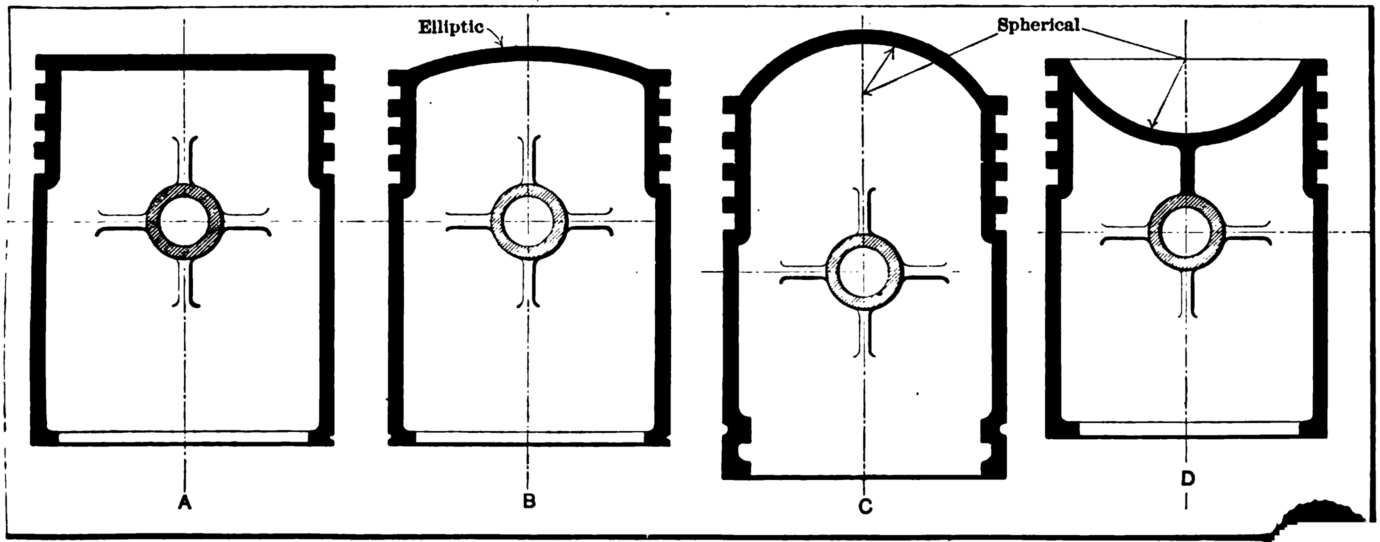

Fig. 4—Depicting various types of pistons, only one of which is satisfactory

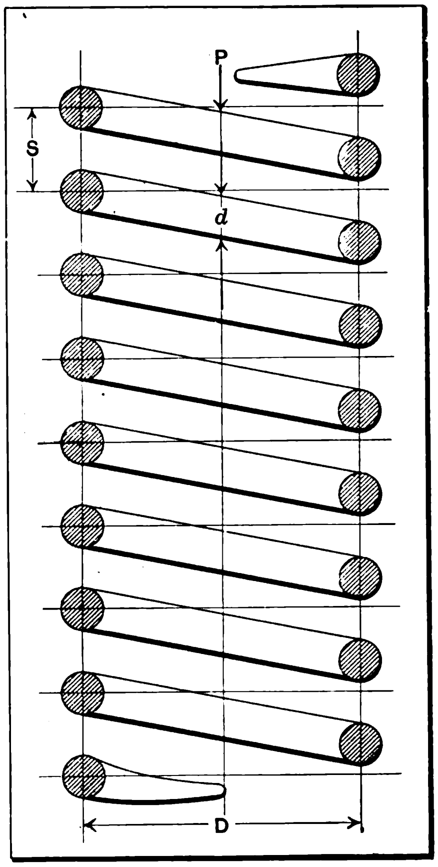

Fig. 5—Diagram of a valve spring to be used in conjunction with the table in Fig. 6

sparking was in the neighborhood of 1,000 r.p.m. Several different coils were used, but no great difference was noted in the sparking.

(185)—In view of the extended use of the Wheeler & Schebler carbureter in racing work, considering its simplicity of design, and remembering that many foreign makes of carbureters are almost as complicated as motors, considering further the fact that detailed information is not obtainable from racing reports, it becomes of interest to learn something of the detailed performance of this carbureter. Can you give the information?

The following test of a Wheeler & Schebler carbureter conducted in accordance with the directions usually furnished by the maker, speaks for itself:

Three runs were made with a No. 5 needle, and the best run is chosen to show the action of the carbureter. Other runs were made, among which five, using a No. 7 needle, but it was found that up to 1,200 revolutions per minute there was no appreciable difference. Beyond 1200 revolutions per minute the No. 7 needle produced a better result. The carbureter performed favorably throughout the range of working speeds of the motor. It was found, of course, that at very high speeds the torque of the motor fell away, but it was not shown that this dimension in torque was due to the carbureter, although it is quite well understood that carbureter problems become serious at high motor speeds. However, the fact remains that motors do not thrive at high speeds.

WHEELER & SCHEBLER CARBURETER TEST

Speed	Gross Load, Lbs.	Tare, Lbs.	Net Load, Lbs.	D. H.P.
600	52.00	27	25.00	15.00

2000	43.00	27	16 00	32.00

(186)—Can you show a test of a muffler on a motor which will give an idea of the amount of back pressure induced?

The following is the test of a muffler which was made at the plant of the E. R. Thomas Motor Company, Buffalo, N. Y., by L. C. Freeman, which is fairly representative of this situation. The back pressure is given in pounds per square inch at speeds increasing by 100-pound increments from 400 to 1,500 revolutions per minute, inclusive. The conditions of the test were as follows: The muffler was connected to the motor with 15 feet of 3-inch (outside diameter) steel tubing, having a wall thickness of 1-16 of an inch. The back pressure in this length of tubing was found to be one-quarter of a pound at 1,500 revolutions per minute, but fell to a nominal point at 1,000 revolutions per minute. The muffler was 9 inches in diameter, and the throttle valve was wide open at all speeds during the test. The exhaust, as observed, was a soft, steady purr at all speeds when about two-thirds of the maximum power was being developed. Beyond this point the noise increased somewhat, but it was claimed that this increase was not more than might be expected from mufflers in general. The test was somewhat marred, due to the fact that the muffler leaked around the head.

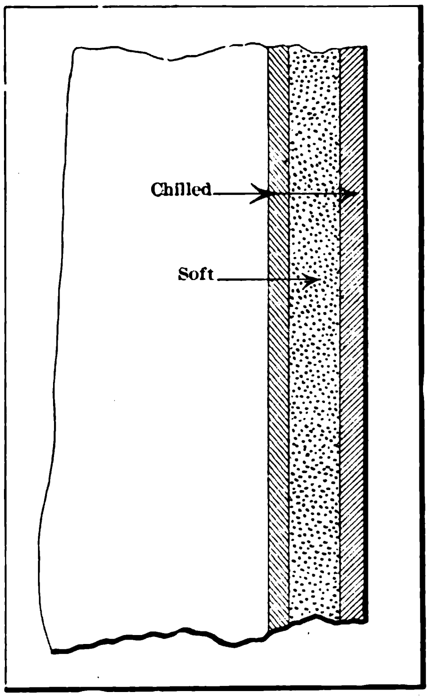

Fig. 7—Section of cylinder wall showing chill metal on surfaces and soft gray iron in the core

DATA OF THE MUFFLER TEST USING A MANOMETER

R.P.M.	Brake	Manometer Inches of Mercury	Back Pressure	H.P.
400	84	1.5	.73	19.2
500	81	1.75	.86	23.
600	75	2.00	.98	26.7
700	67	2.37	1.35	26.8
800	64	B	1.47	29.4
900	64	3.25	1.59	32.8
1000	61	3.75	1.84	34.8
1100	60	4.00	1.96	38.7
1200	60	5.00	2.45	43.3
1300	55	5.25	2.60	40.6
1400	53	5.75	2.80	42.2
1500	49	6.00	2.94	42.0

Note: This back pressure is not unreasonably high. The motor was not developing the maximum power of which it is capable at the speeds given, so the back pressures are correspondingly lower.

Liquid Fuel for Motor Car Engines

By DR. JAMES B. READMAN, F. R. S. E.

Paper read before the Royal Scottish Society of Arts; treats with fuel of various grades; a Sunbeam side-chain drive thermo-syphon car was used; fixed road conditions were adhered to; the fuel used during the trial comprised Borneo petrol, benzol, motor spirits, naphtha, and other distillates in different proportions.

AT a recent meeting of the Royal Scottish Society of Arts a paper was read by James B. Readman, F.R.S.E., giving the results of a series of tests with the various fuels used on a 20-horsepower Sunbeam chain-driven car adapted for the trials. The car had four cylinders, 105 by 130 mm., thermo-syphon cooling; tires, 880 by 120 mm. The main petrol tank was below the driver's seat, and a second one for the experimental fuel was fixed to the dashboard. The tanks were connected by a pipe to the carbureter, which was provided with three-way cock, so that the fuels in either tank might be used at will. To make the results as closely comparative as possible, Dr. Readman selected a suitable portion of the high road leading from Penrith to Appleby. The tests took place over one part of the road, so as to eliminate any difference in gradients, and they were all carried out on one day, to avoid, as far as possible, any climatic changes.

The fuels used were as follows:

1.—Shell Borneo petrol, sp. gr. .720, as a standard well-known fuel.

2.—Ninety per cent. benzol, sp. gr. .880. Engine very difficult to start when cold.

3.—Shale motor spirit, sp. gr. .704. This spirit begins to boil at 44.4 degrees C. (112 degrees F.), and 65.5 per cent. is distilled at the boiling point of water. Engine starts readily.

4.—Shale naphtha, sp. gr. .740. This begins to boil at 82.2 degrees C. (180 degrees F.), and 58 per cent. distils over at the boiling point of water. Repeated trials have proved that the engine starts fairly readily with this spirit, even when all is cold.

5.—Fifty per cent. shale motor spirit with 50 per cent. benzol, sp. gr. .785.

The incoming air to the carbureter in the type of motor used is heated from the exhaust gas pipe. No attempt was made in any of the experiments to alter the float of the carbureter.

Results of the Tests.

The following tables give the results of the tests:

One-fifth of a gallon of each fuel was used. Four persons were in the car. Dusty road. Weather and temperature: Sunny; 54 degrees F. Weight of car (empty), 30½ cwt.

Fuel.	Miles per hour.	Time. M. S.	Distance. Mls. Yds.	Fuel per car mile. Gals.	Miles per gal.
1	26.2	8 26	3 1177	.054	18.3
2	24.8	10 0	4 250	.048	20.7
3	25.2	8 40	3 1110	.055	18.1
4	26.5	8 50	3 1360	.053	18.8
5	26.5	8 34	3 1327	.053	18.7

No smoky exhaust from any of the fuels. The engines pulled well with all except No. 4. The temperature of the water in the radiator was 195 degrees F., at the end of each run, in every case except No. 2, when it was 200 degrees F. Benzol gave the best result—*viz.*, 20.7 miles to the gallon, against 18.8, the best of the other four. Dr. Readman observed no practical [illegible] in the behavior of the engine with the exception of the naphtha, with which it misfired a good deal. A mixture, [illegible] of 40 per cent. of naphtha with 60 per cent. of the [illegible] gave a fairly good result, and one that the car had [illegible] many miles satisfactorily. At the start, however, the engine inclined to misfire for a short time. He said that with an auxiliary tank for motor spirit or petrol to start the engine, the use of the home product, benzol, could not be too strongly recommended, and its further production encouraged. The use of Scottish shale spirits offered a good alternative fuel. Its strong odor, however, was a drawback to its general use.

Dr. Readman gave the results of two comparative trials to ascertain what difference, if any, there was in the fuel consumption when removable non-skid bands were used on the two back wheels, compared with the same wheels uncovered. The road selected for the first trial was an extremely hilly one in Cumberland. In one stretch of 1,184 yards the rise was 280 feet, the gradient going to one in five in places; the total length of the round was 3.51 miles. The speed was maintained as near as possible the same in each trial, and both were made over the same road, in the same direction. A known quantity of motor spirit—more than sufficient to take the car the distance stated—was put into the auxiliary tank, and the quantity left over after the completion of the run was deducted, thus giving the amount actually consumed. The results from the first trials were:

Load three persons; dusty road	Plain tires	Non-skid bands (a)	Non-skid bands (b)
Total distance (miles)	3.51	3.51	3.51
Time (minutes)	13	13.6	13.40
Average speed miles per gallon	16.2	16	15.4
Petrol used (gallons)	.3292	.326	.311
Petrol used per mile (gallons)	.0937	.092	.088
Miles per gallon of petrol	10.6	10.7	11.2

The next two experiments were done on the Penrith to Appleby road, where the conditions, both of surface and gradient, were in strong contrast to the first tests.

Carload four persons; dusty road	Plain tires	Non-skid bands
Total distance (miles	3.1110	3.833
Time (minutes)	8.40	9.7
Average speed (miles per hour)	25.1	22.8
Petrol used (gallons)	1-5th	1-5th
Petrol used per car mile (gallons)	.055	.057
Miles per gallon of petrol	18.1	17.35

Importance of Sturdy Accessories Recognized

Farming as it is done by the makers of automobiles is confined to the parts they are unable to produce (a) as cheaply as they can purchase them (b) with the facilities at their disposal. Accessories are divided into classes as follows:

(A)—Complete car units, as motors, transmission gears, steering gears, live rear axles, front axles, wheels, rims, tires, magnetos, carbureters, radiators, and such other aggregations as are essential to the completion of the chassis independent of the body.

(B)—For the completed chassis, with a view to bringing it up to the user's requirement, the further considerations are by way of bodies, tops and the incidentals for comfort.

(C)—Accessories along necessary lines independent of the chassis and body work include lighting systems, etc.

In the plants where automobiles are made, farming is mostly confined to the production of parts from designs by the makers of the cars, and as a rule, these parts are delivered in dissembled lots to be used as the occasion requires in the assembling of the automobiles. It was thought for a time by some who take an interest in such matters that farming would ultimately pass out of vogue, for two reasons, (a) on the ground that a maker of automobiles can not long afford to allow a portion of his earnings to be absorbed by parts makers, and (b) for the reason that a better quality is to be expected if responsibility is centered. Thus far in the history of the industry it has not been shown that any of the reasons given have much weight alongside of the fact that a maker of specialties becomes skilled in the art, and he must make good because his bread and butter lies in maintaining a satisfactory standard of quality; in other words, the accessory maker has every chance to learn how to do the work rightly and his success depends entirely upon quality.

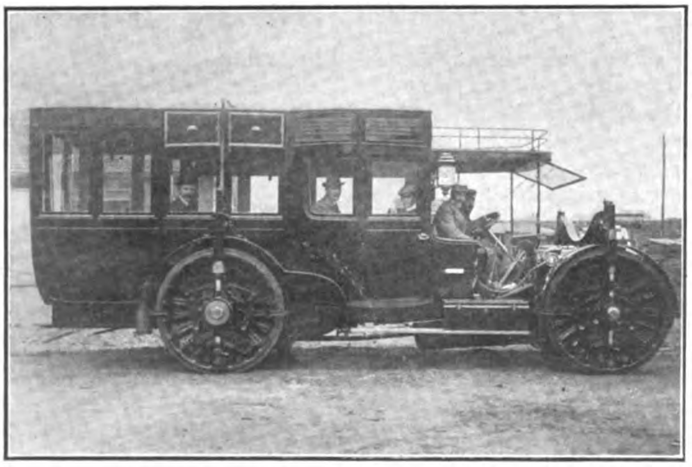
Trying to Abolish the Use of Rubber Tires

Depicting a system which is a radical departure from accepted practice; low center of gravity is one of the aims; how it is realized is shown; suspension is from above instead of from below; large diameter wheels are used; the plan has been given a practical try-out; instead of tires of rubber or steel, a system of leather bandages is used; the scheme looks heavy, but the designer thinks that quantity building will soften this defect.

WITH rubber at a record price and still rising, inventors of spring suspensions, shock absorbers, and other devices intended to abolish the use of pneumatics or to lengthen their natural life, find this the right moment to bring their wares before the public. J. J. Heilmann, a French engineer of considerable repute, has a system which is a radical departure from the standardized method of suspending automobile vehicles. He objects to the small wheels used on automobiles in order to obtain a low centre of gravity; he considers that the overhanging suspension in relation to the vertical passing through the axis of the wheels and the point of contact with the ground is contrary to engineering principles; and naturally he is of the opinion that pneumatics are out of the question where economy has to be considered on heavy commercial vehicles.

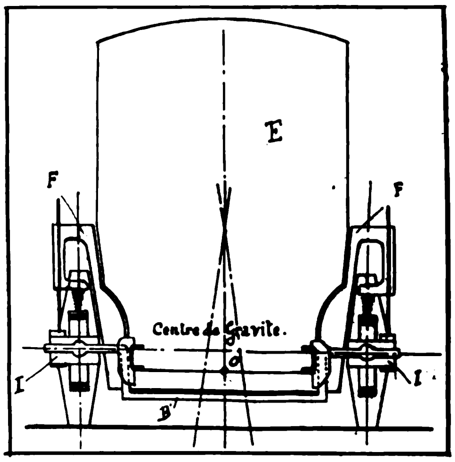
The principle of the Heilmann suspension can be gathered on reference to the figures. The vehicle is no longer carried from below, but is suspended at FF" in the vertical axis of the road wheels, and on their hubs II". The axle, B, is entirely free, merely carrying its own weight, serving to unite the two wheels, and guiding the chassis and the body in fixed grooves attached to the chassis. As the body is not laid on the springs, but is suspended from above, all swinging of the upper portion is abolished. Although the wheels are almost twice the diameter of those usually employed, the centre of gravity is brought down to O, below the axis of the wheels, and the body is as near to the ground as with the ordinary system of suspension. Further, by the interposition of a universal joint in the axle, each wheel can respond to road inequalities without a twisting of the chassis, or in any way affecting the opposite wheel.

Engineer Heilmann has given a practical application to his system on a Pipe six-cylinder chassis, fitted with a handsome 22-passenger saloon body. Very satisfactory experiments have been made, and although some changes will be carried out before construction in series is commenced, these will be of a structural nature only, the principle remaining unchanged. The wheels, as can be seen from the illustrations, are metal ones of very large diameter, with all the suspension in the vertical axis. This consists of two short semi-elliptic springs, one above and one below the hub of the road wheel, and two hydraulic shock absorbers. By reason of the large diameter of the wheels and the various organs of suspension all vibration is abolished. The distance that vibrations have to travel from the rim to the road wheel to the chassis is over 14 feet, compared with an average of 50 inches on automobiles with the usual small diameter wheels and semi-elliptic springs.



Pipe 6-cylinder saloon body by Labourdette of Paris "compound," Heilmann suspension

Neither pneumatic nor solid tires are necessary. The inventor would prefer to use metal bandages, but on account of their side-slipping propensity and the noise they make he has discarded them for a patented compressed leather bandage. This has no resiliency, but it deadens noise and prevents slip. The external appearance of the suspension suggests considerable additional weight, but according to the inventor the system is lighter than wooden wheels, solid rubber tires and semi-elliptic springs, as ordinarily used. Complete with 23 passengers, the Pipe saloon car with the Heilmann suspension weighs from 11,000 to 13,000 pounds, according to the nature of the passengers. When built in series very much weight will be saved, for the first model is almost entirely in cast steel, with a very large safety margin. Steel stampings could be used for most of the metal parts, with, of course, a great decrease in weight. By the use of air buffers Engineer Delpeuch has found it possible to abolish the use of springs, as well as pneumatic tires, for motor vehicles of any size or weight. Briefly, his system consists of four cylindrical air buffers, in place of the four springs. The usual way of converting an ordinary car is as follows for the front suspension: The semi-elliptic springs are entirely dismounted, and the frame members are sawn off about an inch ahead of the front of the radiator. To this projecting end is attached a wrought-iron vertical member, the upper curved end of which receives the head of the cylindrical air buffet. In order that the harmonious lines of the car may be observed the frame to carry the cylinders is a scroll work, generally with one arm made to support the front end of the mudguards. The connecting rod of each piston is bolted to the axle in practically the same way as springs are attached. An effort is made to provide against shock which is more pronounced in this plan than with springs.



Sketch showing principle of Heilmann suspension

Two small tanks, carried within the frame, contain compressed air for the suspension, one tank feeding the two front buffers, and the other the rear ones. The air is put under pressure through a dashboard connection, either by means of a tire pump or a mechanical tire inflator. On the dashboard, also, are two manometers, indicating the pressure in the forward and the rear pair of cylinders, and provided with cocks for passing the pressure from one set of buffers to the other, as desired. Thus it is possible to increase the pressure at the rear and decrease it at the front, or *vice versa*.

The cylindrical buffers are each fitted with a special piston capable of holding compression equal to that usually maintained in pneumatic tires. This is obtained by a piston without compression rings, the nature of the metal being a secret of the inventor, and covered by a patent. A charge of lubricating oil is placed in the cylinder when fitted, and this is generally sufficient for the normal life of the piston. As a proof of the entire absence of leakage a set of buffers fitted to a car were inflated to the normal working pressure of 5 kilogrammes and left untouched for four months; at the end of this time the loss from all causes was less than half a kilogramme.

Suitable piping, a part of it being flexible rubber tubing, united each buffer to the compressed-air tanks. In the head of the cylinder is an ordinary type of automatic valve which opens in the direction of the tank on the rise of the piston due to a road shock. Immediately on the pressure being released, the valve closes and air begins to pass through a hole in the centre of the valve until the pressure in the buffer has been re-established. In practice, over a rough road, the valve is continually being opened by the repeated road shocks, and just as frequently air is flowing back from the tank to the buffer.

The system has been found so satisfactory that it is possible to do without both springs and pneumatics. The car shown in the illustration is temporarily fitted with pneumatic tires, because no satisfactory solid tire was immediately available. It is found that best results are obtained with a tread of two inches for a medium-sized car, the rear bandage being fitted with diagonal grooves as a preventative of side slip. It is also necessary that the metal rim shall be of such a nature as not to come in contact with the rough ground surface. This type of rim and bandage is now being made specially for the suspension. As a practical test two cars were presented, one with the Delpeuch air suspension, and the other with ordinary springs and pneumatic tires. Experienced automobilists were taken a night ride in both over some of the worst paved streets around Paris, without knowing in which car they were seated. In no case was it found that the air suspension was the less advantageous.

A strong point of the system is that it is possible to vary the pressure according to the load to be carried, or to decrease or increase pressure at front and rear, as is desired.

Technical Tests of the Partington Spring Wheel

COMMANDANT L. FERRUS presents a report on the Partington spring wheel submitted for trial to the Technical Commission of the Automobile Club of France. The wheel is of the type with a rigid rim sliding in grooves fixed on a central hub, also rigid, with the elastic medium placed between the rim and the central hub. Its distinguishing feature is that instead of the elastic medium consisting, as usual, of springs or solid rubber, it is here composed of an air tube. Following the letter references in Figs. 1 and 2, the characteristic of the Partington wheel is the absence of a special organ forming a locking mechanism between the rim G and the hub. This latter is really composed of a complete wheel, the rim of which, A, is undulated. The encircling band, on the contrary, carries a hollow toothed rim, A1 A2, composed of fiber and canvas, the teeth of which, A1, and the hollows A2 correspond respectively to the depressions and the projections of the interior rim, Figs. 1 and 2.

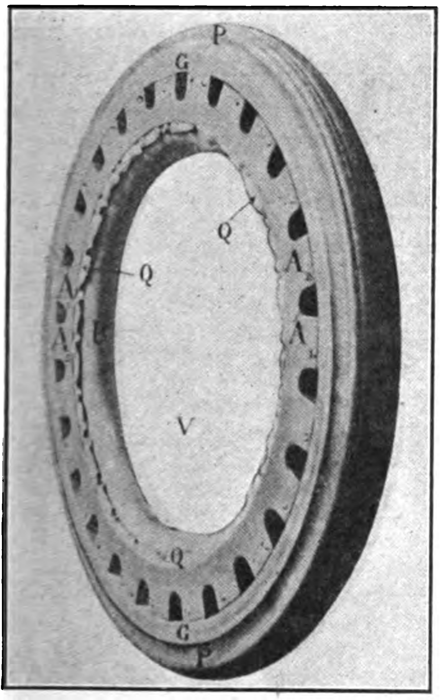


Fig. 2—Partington spring wheel, sectional view

A reinforced air tube, protected by a thick bandage of chrome leather, Q, is interposed between the rim A and the toothed circle, A1 A2 A1 A2. This tube is inflated to a pressure of 5 kilos and enters between the depressions and the projections of the two undulated surfaces, facing one another and makes them into a rigid whole.

Two circular discs are attached by bolts to the rim, and united between them by the bolts which pass through the openings A1, forming a sliding groove for the rim G, and the hollow circle, allowing them to oscillate radially or tangentially between these flasks, while at the same time resting in contact with the air chamber, B. The bolts F limit, in case of necessity, these oscillating movements.

It will be seen that the rim is driven without any difficulty and that the central hub is freely suspended in the interior of the air chamber without transverse rigidity being impaired. When starting the hub turns very slightly in relation to the rim G and the hollow rim A1 A2, bringing them into movement with an elastic motion and without any shock. When stopping or braking, an inverse movement takes place. It is found that starting and stopping take place without any shock. No displacement of the air chamber takes place by reason of the large number of teeth in the two rims. Any such movement would tend to tear out the valve, and tests have shown that the valve is not in any way affected. The flexibility of the bandage is very satisfactory. On an indifferent or really bad road it is equal to that of a pneumatic tire. On an ordinary road, and especially on one with few rough places, there is less flexibility than with a pneumatic tire, for this wheel does not "absorb" small obstacles; the car holds well to the road, even at high speed and on turns.

Objections are that the wheel is rather heavy, and that this may have an ill effect on the axle stubs; this difficulty should be overcome by better methods of construction. Price is high, but is compensated by the lower cost of upkeep. Due to wear the air chamber may not remain air tight. These objections, however, appear to be more theoretical than real.—*Bulletin Officiel de la Commission Technique de l'Automobile Club de France*, April, 1910.

Digest Along Technical Lines for the Engineer

Throttling and lubrication in revolving-cylinder motors——Gasoline motors with reserve power——The possibilities for developing them——The Gore construction——Nervous or soft motors——Their torque and their wear——More light on concentric valves.

Comparing the Gnome and the Adams revolving motors, Eric Walford gives credit for the early conception and practical work of the Adams-Farwell construction and finds them similar in principle. While the greater lightness belongs to the Gnome, the Adams has important constructive advantages. The power of the engine is controlled by varying the compression. A lever permits the adjustment of the inlet cam with relation to the revolving engine. For full power the cam operates as usual, but otherwise the inlet valve remains open during part of the compression stroke, so that part of the gas is blown back in the inlet pipe and less is compressed. This has the advantage that, when the engine is throttled down considerably, the pressure within the cylinders does not fall very low on the suction strokes, as in ordinary engines, and the lubricating oil will not be liable to be drawn past the piston rings into the combustion chamber. By this provision one of the great difficulties of revolving motors seems to be obviated in the Adams type. It has no exhaust pipe or muffler, but auxiliary exhaust ports at the bottom of the stroke break up the exhaust into two portions and reduce the noise. The gas is not fed into the crank chamber, as in the Gnome, but into an induction chamber and thence through five radial inlet pipes to the tops of the cylinders, so that this engine does not resemble the radial-flow turbine as much as the Gnome, in which the gas travels radially outward through valves in the piston head, and then expands inward, passing outward through the cylinder heads again on the exhaust stroke.—*The Autocar*, June 4.

Not the flexibility but the reserve power of the steam engine is the envied feature with which designers of gasoline motors have recently been trying to endow their creations. There is after all sufficient flexibility and suppleness in a six-cylinder or an eight-cylinder engine or in a four-cylinder engine of the two-cycle system. But the maximum value of the mean effective pressure is a strictly limited quantity obtained only when the cylinder receives its maximum charge of gas mixture. And the maximum charge is only obtained at low-motor speeds. Above a certain number of revolutions the power of any motor ceases to increase in proportion to its speed. The piston speed is limited by the increasing resistance to aspiration of gas, more than by inertia or the difficulties of lubrication, which, however, also make themselves felt and impose another, but higher, limit to the increase of power. The pressure on the steam piston, on the other hand, is only limited by that on the boiler walls which may be raised by more intense heat. Now it is a question if the loss of charge at the moment of gas induction could not be suppressed and whether in fact the charge might not be increased beyond the natural cylinder volume, since there is nothing inconsistent in having the charge at more than one atmospheric pressure, by means of a system of forced feed for the gas. The danger of automatic ignition limits the pressure that might be employed, of course. But suppose we admit into a cylinder of one liter volume 1½ liters of gas which we compress three times, or to 4½ kilograms per square centimeter, and in another cylinder of the same volume we admit ¾ liter of gas compressed six times, giving the same pressure as in the first case. The volumes occupied by the gas after the explosion will be identical at the moment the exhaust is opened, and, as the first contained twice as much gas as the other, it stands to reason that the pressure in the first, at the moment of exhaust, is greater than in the other, and indeed as great at the bottom of the stroke as it was at the middle of the stroke in the second cylinder. Consequently, if one has obtained a higher mean effective pressure in the first case, one has also a poor efficiency, since the expansion of the gas has not been well utilized.

There seem to be three possibilities for raising the present maximum power of the motor:

(1)—To find means for introducing a charge reaching a little above atmospheric pressure at the end of admission, even at high speeds.

(2)—The gas admission is not limited but varied according to the power demanded of the motor, while the compression is designed so as to be about normal, 4kg. per sq. cm., when the charge is admitted at atmospheric pressure, and the gasoline is not injected till the moment the explosion is wanted, thus excluding premature ignition when an overcharge has been admitted and the compression consequently raised. The efficiency with this method remains fair, since the conditions are normal for normal operation, and under the forced regimen the resulting overcompression compensates in part for the incomplete expansion.

(3)—The gas admission is not limited, but the volume of the compression chamber is varied so as to have no overcompression or premature ignition. The efficiency in this case is good, so long as the charge remains below atmospheric pressure, but beyond this the incomplete expansion causes a lessened efficiency which, however, is admissible, since the forced march is the exceptional expedient for overcoming exceptional resistance.

The second solution of the problem seems to offer the best averages for all speeds and many designers are working it out experimentally. Nevertheless, it is the first solution which has been taken up successfully in the Gore motor. This comprises five vertical cylinders in a row, working on crank pins 72 deg. apart. A sixth cylinder is the air compressor, which sends air to a tank, whence it goes to the cylinders, passing on the way through a carburetting or gasoline-injector device, but a hand-operated valve on the air conduit permits the operator to shut off the compressed air. The carburetion takes place as follows: The compressed air passes with great speed into a double horizontal cone, siphoning into this cone whatever air can penetrate from the atmosphere by raising a small valve below the gasoline jet (jet and valve both located in vertical tube extending below the cones). A separate oblique needle valve below the valve admits regulation of the air thus drawn in and thereby of the degree of carburetion. So that the compressed air shall not raise all the induction valves at the same time but allow them to remain under control of their respective cams, the inventor has recourse to compensating valves, on the same plan as in Doué's automatic starting device. The holes bored in the cylinders for the guides of the valves are in this motor of a diameter equal to that of the valve, and the valve guides slide in them, while the valve springs are lodged in seats hollowed out in the guides. At rest the latter abut against a portion of the cylinder by means of a flange, but as soon as compressed air enters the admission chamber below the admission valve and surrounding the upper part of the valve stem, the pressure on the top of the guide makes it descend to its seat with a force equal to that which tends to open it by direct air pressure, the lower area of the valve being equal to the top area of the guide, as mentioned.

The inlet cam shaft can be made to slide longitudinally, thereby varying the period of admission for the compressed gas.

Normally, the admission closes at 15 per cent. of the stroke, but at the forced regimen it remains open for 0.30 of the suction stroke. The gas admitted during this period is under a pressure of about 3.5 kg. per sq. cm. and distends during the rest of the suction stroke, till at the end it is at 0.52 of one atmosphere in normal operation, but at 1.05 atmosphere when the motor is forced. In an ordinary motor the pressure on the charge at the end of the suction stroke is about 0.65 atmosphere at 1,500 r.p.m. One may ask if this first compression by a pump followed by expansion in the cylinder and by a second compression in the cylinder does not involve losses. But the first expansion is a motor power and contributes to cooling of the motor. On the other hand, there must be losses in the conduits made necessary by the system. At small speeds, the system gives ten motor impulsions for each two revolutions; namely, five explosions and five admissions of compressed gas. To complete the analogy with a steam engine, the Gove motor has, besides the cams of varying profile permitting variable duration of gas admission, also double admission and exhaust cams permitting the engine to be reversed. The starting of the motor is automatic. It is only necessary to open the shut-off valve for the compressed air and the latter finds the cylinder whose admission valve is open and starts the motor even under load.

The inventor states that a motor of his construction with cylinders 90 by 127 mm. gives 50 horsepower at 1,000 r.p.m. and with a full consumption of 215 cubic centimeters per hp-hour. The mean effective pressure is given as 15.7 kg. per sq. cm., which, however, exceeds the power mentioned by 3-7 kg. Doubtless the inventor is optimistic, as an ordinary motor of his dimensions, with allowance for the large gas charges, should not give more than 42 horsepower at the most.—From reprint in *Automobile-Aviation de Belgique*, June 30.

With reference to concentric valves, of which a comparative study was presented in these columns on June 9 after *La Vie Automobile*, the maker of the Miesse motor and valve offers remarks of general interest in objecting to the reviewer's estimate of his construction. It can not be considered objectionable, he writes, that the valve lift reaches as high as 10 millimeters. The shock on the tappet roller is no more sudden than with ordinary construction, since the projection on the cam is divided in two advances no higher than those of an ordinary cam, and, as to the drop, it is effected at an angle differing considerably from that indicated in the illustration, so that the possibility of fracturing the parts is entirely obviated. It seems at all events simpler and safer to employ a positive mechanical movement for raising the valves than the variable and problematic action of a counter-spring. While the interval between the upper exhaust valve and the intake valve at the bottom contains burnt gases which enter the cylinder again at the suction stroke, this is no more than takes places in all ordinary motors with L. or T. valve chambers, while in the Miesse construction the space referred to is closed between the valves during the explosion stroke and does not affect the thermic efficiency. It is stated that the exhaust valve, whose central location distinguishes this system from all other concentric valve designs, is never cooled. In reality it has been placed where it is precisely with a view to obtaining perfect cooling, and in its position lies the superiority of the system. In none of the other designs does the cooling medium come in contact directly with the seats of the valves or the valves themselves, while in the Miesse the air is driven with great force by the ventilating fan directly against the large exterior valve and its seat; and, besides, the fresh gases lick the exhaust valve seat exteriorly and, as the surface of the valve proper is much smaller than that of the seat which always remains cool, it is readily seen that the cooling is effected much more surely and rationally than in the usual case, where the question is that of cooling the largest of two valves. In other words, it is easier to cool a small than a large valve. In the Miesse motor there is moreover provided an auxiliary exhaust at the bottom of the stroke which notably diminishes the quantity and heat of the gas passing through the exhaust valve.—Letter from J. Miesse to *La Vie Automobile*, June 4.

Various methods for blueprints, and a suitable equipment of a modern factory for this purpose are described by Reishaus in *Werkstattstechnik* for April, with drawings of the blueprint machines made by Halden & Co., of Manchester, Eng.

On the subject of "nervous" or "soft" motors, A. Contet, a well-known French engineer, maintains that the distinction, while popular, is devoid of genuine merit and is dictated mostly by commercial considerations. The "soft" motor with the customary short stroke and moderate compression gets all the characteristics of the "nervous" motor at low motor speeds, while the "nervous" motor under an overload forcing it to small speed becomes "soft." The question is one of torque at the various motor speeds. The torque of the short-stroke motor (or 110 by 120 millimeters) of the heretofore ruling design is generally superior below 1,500 revolutions per minute, while that of the long-stroke motor, developing the same power with 85 millimeters bore and 160 millimeters stroke, is superior above 1,500 revolutions per minute. With regard to the bearings of the long-stroke motor, Contet maintains that their rapid wear is simply due to the erroneous practice of using only two bearings for the shaft of a four-cylinder motor, which compels the use of very large diameters and consequently rapid wear of connecting rod bushings, due to the high linear speed. He considers that every "pushed" or "nervous" motor should necessarily be equipped with five crankshaft bearings for four cylinders, so that crackpin diameters may be reduced to their minimum, and that these bearings furthermore should be ball-bearing, so as to give room for widening the connecting rod knuckles and diminishing the pressures per square inch. By this means the pushed motor may be made just as durable in all its parts as the customary type.—A. Contet in *L. V. A.*, June 25.

Valuable articles on steel testing, very elaborate; on electric heating and pyrometry; on case-hardening and on the A2 point in chromium steel, are found in *Engineering* (London) for June 3 and 17.

A method for testing iron and steel shapes for defects by means of corrosion, which quickly lays bare the dangerous formations, is described and proposed by Charles Frémont, engineer, in a quarto pamphlet of 54 pages, with 41 illustrations, published by Dunod & Pinat, Paris; price, 2 francs. The same author has an article on the dynamics of the screw, with special reference to accurate determinations, as for use in dynamometers, in *Revue Mecanique*, May 31.

Referring to a loss of "aerial pilots" making a total of 81, *Motor Car* (June 8, 1910) goes on to say: "Here we get some idea of the commerce done by the different firms, for by looking over this list we find twenty-five H. Farman biplanes, twenty-two Blériot monoplanes, ten Voisin biplanes, nine Wright biplanes, six Antoinette monoplanes, and ten other different types. It is not easy to ascertain the true number of aeroplanes and airships, but the total is about 345, divided amongst the principal countries: England, 20 aeroplanes, 4 dirigibles; France, 190 aeroplanes, 10 dirigibles; United States, 50 aeroplanes, 7 dirigibles; Germany, 15 aeroplanes, 16 dirigibles; Italy, 15 aeroplanes, 3 dirigibles; Japan, 5 aeroplanes, 1 dirigible; Austria-Hungary, 10 aeroplanes, 1 dirigible; Belgium, 8 aeroplanes, 2 dirigibles; Russia, 6 aeroplanes, 2 dirigibles.

Testing Steel—For Impact, Bending, Etc.

By BERTRAM BLOUNT, W. G. KIRKALDY and Capt. H. RIALL SANKEY

(Fourth Installment)

It was found that the average of 4 test pieces when broken by repeated bending was within 4 per cent.; a greater variation was traced to effect of position; appearance of fracture same as that due to static testing; energy required for rupturing can be calculated; measurements of strength discussed.

FOUR test-pieces were broken for each type of steel by repeated bending, and the average disparity of the various observations from the mean was of the order of 4 per cent.; where greater variation than this occurred it could be traced to the effect of the position of the test-piece; the effect of position is very marked in some cases. The readings of the maximum bending effort of each set of four test-pieces are much closer than those of the bending effort of the first bend. It would appear that the latter depends a good deal on the position of the test-piece and also on the degree of annealing. The effect of the bending is to stiffen the material, and apparently this stiffening tends to a limit; hence a greater uniformity in the readings of the maximum bending effort which agreed within 2 per cent. In the case of the initial bending effort the disparity is as much as 4 per cent. Except in a few cases, the number of bends sustained by each of the four test-pieces of a set agreed within 6 per cent, and the measurement of energy absorbed agreed within the same percentage. In most cases the disparity can be accounted for by the effect of the position from which the test-pieces were taken, but in some there is no apparent explanation. A note was taken of the position of the skin with reference to the direction of bending, but no decided effect was observed.

The appearance of the fractures of the impact tensile tests agreed with those of the static tensile tests. The fractures of the repeated-bending tests had, however, a somewhat different appearance, but no better terms than silky and granular suggest themselves. In addition to these two kinds of fracture, small bright crystalline patches were observed in some cases (see Items Nos. 8 and 9, column 25, Table 2. As a rule, it is possible to find a likeness between the various fractures sufficient to classify them.

Comparison of the Results Obtained.—Broadly stated, the object of applying a mechanical test to a piece of steel is to obtain information as to its strength, its ductility and the energy required to rupture it. Although the energy required for rupture can be calculated from the ordinary tensile tests it is not usual to do so. In the case of impact tests it is the principal measurement made; in fact, with notched specimens it is the only measurement possible. As regards repeated bending the energy absorbed is automatically recorded by the machine used in these experiments, as already explained.

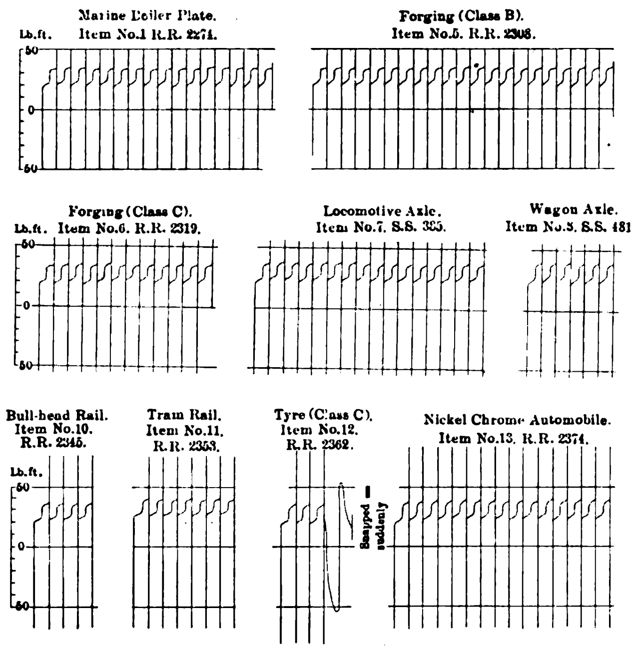
Measurement of Strength.—Some idea of the strength can be obtained from the impact tests by dividing the elongation into the energy absorbed per cubic inch, i.e., column 13, Table 3, by column 17, Table 2; this has been done and result is given in column 3, Table 3, and the ratio of column 3 to the breaking stress (column 7, Table 2) is given in column 4. There is a fair agreement proportionately, but the strength is exaggerated.

In the case of the repeated bending it is clear that there must be some connection between the initial bending effort and the yield stress, and it is probable that there is also a relation between the maximum bending effort and the breaking stress.

These comparisons are given in Table 3, columns 5 and 6, and it will be seen that as regards the yield stress and initial bending effort the average ratio is 2.1 for steels containing up to about 0.3 per cent. carbon, and it may be stated that practically the same figure has been many times obtained before with steels of similar carbon content. For steels containing more carbon, however, the ratio is greater, namely, an average of 2.7. The nickel chrome steel does not, however, conform to this rule, nor is the agreement good in the case of items 1 and 2. The disparity may, however, be in some measure due to the known difficulty of accurately determining the yield stress. The ratio of the maximum bending effort to the breaking stress is very fairly constant throughout, the average figure being 1.54, and the greatest disparity is 7 per cent.

The meaning is that an approximate idea of the tensile yield stress can be obtained by dividing the initial bending effort by the 2.1 in the case of mild steels (below 0.3 carbon) and by 2.7 for stronger steels. In all cases the tensile breaking stress can be calculated to a fairly close approximation by dividing the maximum bending effort by 1.54. These results are also shown diagrammatically in Fig. 9.

Measurement of Ductility.—The impact-tensile test gives elongation and contraction of area, and it is to be noticed that the figures are in all cases greater than those obtained with the static tensile tests of the small specimens. As regards elongation the probable explanation is that the suddenness of the breaking effort tends to produce a more general extension. In the repeated-bending test the number of bends increases with the ductility, and in order to establish a comparison with the ductility as evidenced by the tensile tests, the ratio of the number of bends to the elongation,* to the contraction of area, and to the product of the elongation and the contraction of area have been computed with the results given in columns 8, 9, and 10, Table 3. It will



Item No.	Type of Steel.	Min.	Max.	Emergy.	No. of Bends.	Fracture.
		lb.-ft.	lb.-ft.	ft.-lb.		
1	Marine Boiler Plate . .	45	51	2,300	31	silky

Fig. 8—Records of repeated-bending tests on nine types of steel

---

* In order to make a true comparison the elongation for a gauge length of $4\sqrt{A}$ has been computed from elongations given in columns 8 to 12, Table 2. A is the area of the cross-section.

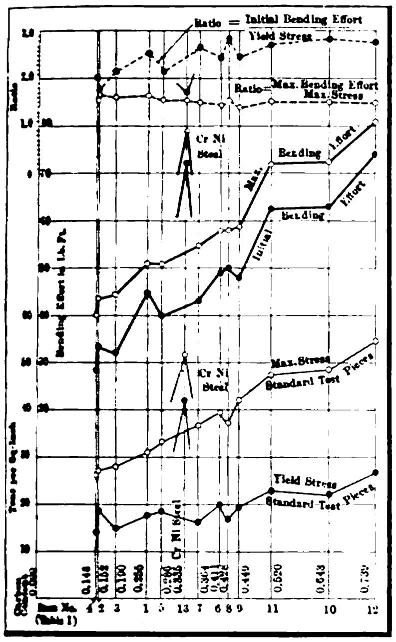

Fig 9—Comparison of repeated-bend tests with tensile tests

be seen that the ratio varies somewhat in the first two cases, but is fairly constant in the last (column 10). It may be said therefore that the number of bends is proportionate to the ductility as obtained by the static tensile tests. These results are also shown diagrammatically in Fig. 10.

Measurement of Energy Absorbed.—A comparison of the energy absorbed in rupturing the test-pieces by the three different methods of test is given in columns 11 to 17, Table 3. In the static tensile tests the formula used is:

Energy per cubic inch

$$= \frac{\text{elongation}}{\text{gauge length}}\left(\frac{2\text{ breaking-stress} + \text{yield-stress}}{3}\right).$$

This formula assumes that the top of the stress-strain diagram is sensibly parabolic in form, and it was originally proposed by Sir Alexander Kennedy. The calculation has been made both for the small and for the standard test-pieces; in the latter case the elongation for a large test-piece geometrically similar to the small test-piece was computed. It will be seen that the energy per cubic inch absorbed by the large test-piece is in all cases smaller than by the small test-piece.

It will be further noticed that the energy absorbed per cubic inch in the impact tensile test is considerably greater than in the static tensile test, the ratio being approximately 1.6 (see column 14) which may be due to the suddenness of the action.

On examining the broken repeated-bend test-pieces it was found that the whole of the metal was profoundly disturbed for about 1.3 inch of its length (varying from 1.1 to 1.5). The energy per cubic inch can, therefore, be calculated approximately, and the result is given in column 15, Table 3. It will be observed that the figures in most cases are of the order of five to ten times greater than those for the static tensile tests (standard specimens, column 12). In the case of the latter, however, the far greater portion of the metal is only distributed to the extent due to the yield stress (even if so much), and it is only close to the actual fracture that it is fully disturbed, whereas in the bending test, as already pointed out, nearly the whole of the test-piece is profoundly disturbed. An estimate of the energy absorbed in the neighborhood of the point of rupture in the tensile test can be obtained as follows: The energy absorbed per cubic inch by the general extension can be found by establishing simultaneous equations based on the elongation on 2 inches and on 3 inches given in columns 8 and 9, Table 2. To this must be added the energy per cubic inch required close to the point of fracture by the additional disturbance there. A cubic inch, consisting of a cylinder 1 square inch area and 1 inch length, will be deformed into a cylinder whose cross-section is that of the contracted area. The elongation of this cylinder is, therefore:

$$\frac{1}{1-\text{contracted area}} = l$$

and the force acting is the breaking stress. This energy can therefore be calculated and added to that due to the general elongation. The result is given in column 16, Table 3, and the ratio of the energy required by repeated-bending to this energy is given in column 17. It will be seen that the ratio is fairly constant, and roughly the energy per cubic inch required by repeated bending is twice that needed by a static pull at the point of maximum disturbance. This appears reasonable seeing that the alternate tensions and compressions to which the metal is subjected in repeated bending produce an irreversible action, so that the energy required is likely to be considerably greater than that needed for a simple pull. An interesting point to note is that the variation in the energy absorbed per cubic inch, both in the static tensile and in the tensile impact tests, does not greatly vary with the different types of steel; whereas in the repeated-bending very marked differences occur. These results are also shown diagrammatically in Fig. 11.

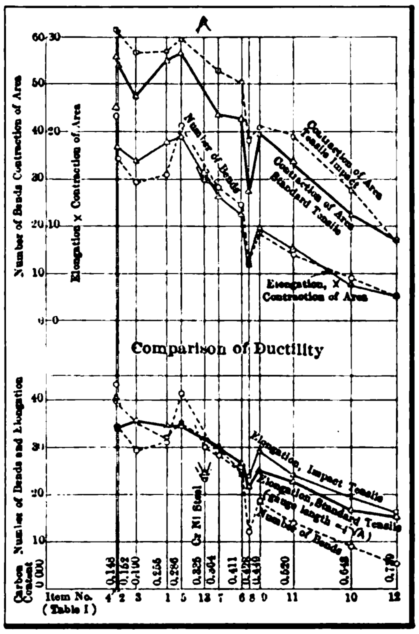

Fig. 10—Comparison of ductility by static tensile, impact tensile and repeated bending

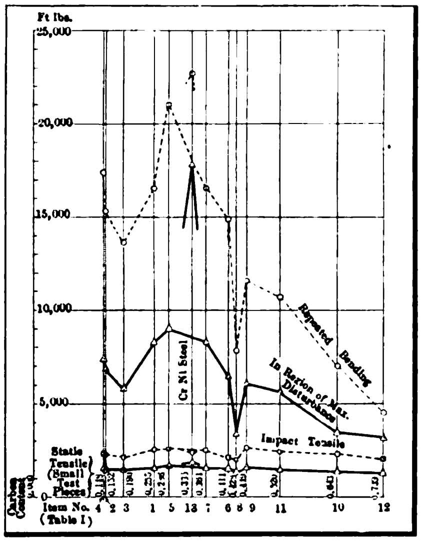

Fig. 11—Comparison of energy absorbed per cubic inch of metal by static tensile, impact tensile and repeated bending

The results of the impact tests are similar to those obtained by the static tension test, and this agrees with similar tests made by M. P. Breuil and others, but it would appear from these latter tests that in the case of steels containing an undue percentage of phosphorus much lower results are obtained by the impact method than by the static method. Such steels were, however, not included in the original scope of experiments.

Summary

1. The static tensile test forms a standard of comparison, and gives the strength and ductility of a sample of steel in terms which are well understood. The average energy absorbed per cubic inch can be computed, but does not vary greatly, and, therefore, does not assist in discriminating between the various types of steel.

2. The impact tensile test gives the ductility in the same terms as the static tensile test, namely, elongation and contraction of area, but always with higher numerical values. The breaking stress of the material can be inferred, but must be reduced by a factor in order to obtain the same numerical values as given by the static test; also it only gives the breaking stress. The energy absorbed per cubic inch does not vary greatly with the various types of steel; it is approximately 50 per cent. more than that obtained by the static tensile test, and is also no definite criterion of the type of the steel; at any rate, of normal steels containing a small proportion of phosphorus. From the experiments referred to by M.

Breuil it would appear that steels containing an undue proportion of phosphorus give a much smaller energy per cubic inch with impact tensile tests.

3. The repeated-bending test gives strength, ductility and energy, but in terms different to those obtained by the static or the impact tensile test. Strength in the same terms as the static test can be inferred as follows:

The yield-point expressed in tons per square inch can be obtained by dividing the initial bending effort, expressed in lb.-ft., by 2.1 for mild steels, namely, those containing less than 0.3 per cent. of carbon, and 2.7 for medium carbon steels. The breaking stress in tons per square inch can be obtained by dividing the maximum bending effort, expressed in lb.-ft. by a factor 1.54 for all types of carbon steel. The ductility of the steel is given in different terms to those in which it is expressed by the static tensile test, namely, the number of bends, but the product of elongation on a gauge length of $4\sqrt{A}$ multiplied by the reduction of area is equal approximately to the number of bends divided by 1.9. The energy expressed in ft.-lb. per cubic inch required for breaking by repeated bending varies considerably, and is a characteristic of the type of steel.

The paper is illustrated by eleven figures in the letterpress and is accompanied by an appendix.

Appendix

The following is the calculation that has to be made to obtain the energy absorbed by the tensile impact test. As given on page 53 (July 14 issue), the formula is:

$$\text{Energy absorbed} = W\left\{H - \frac{1}{2g}\left(\frac{h}{t} - \frac{gt}{2}\right)^2\right\}$$

but since in almost every case the height of fall H was 30 feet, and the fall after fracture *h* was 10 feet, this formula can be reduced to:

$$\text{Energy absorbed} = W\left(35 - \frac{1.553}{t^2} - 4.035t^2\right)$$

Test-piece No. 307, taken out of locomitive plate not subjected to flame (Item No. 3), will be taken as an example; in this case W = 20 pounds and the tape record gave $t = 0.365$ second.

Hence:

$$\text{Energy absorbed} = 20\left(35 - \frac{1.553}{(0.365)^2} - 4.035\,(0.365)^2\right)$$

$$\text{Energy absorbed} = 20\,(35 - 11.64 - 0.53)$$

$$\text{Energy absorbed} = 456 \text{ foot-pounds.}$$

The error in determining the energy absorbed in rupturing a test-piece by tensile impact depends on the error in the time measurement, and also on the ratio between the energy absorbed in breaking the test-piece and that remaining in the tup immediately after fracture.

If δ is the error in the measurement of the interval-time, it can be shown after some reduction* that the percentage of error in the value calculated from the above formula is:

$$\frac{2\delta K}{1 - K^2}\left\{\sqrt{\frac{h}{H} + K^2} - \frac{\delta}{2}\left[\frac{h}{HK} + 2K + \sqrt{\frac{h}{H} + K^2}\right]\right\}$$

where K is the ratio of the velocity of the tup immediately after rupturing the test-piece to its velocity immediately before impact, hence $1 - K^2$ is the ratio of the energy absorbed to the energy in the tup immediately before fracture.

The following numerical examples, set out in a tabular form, will show the per cent error in the energy measurement for various values of K when $\delta = 1$ per cent. and 4 per cent., respectively. In all cases H = 30 feet and $h = 10$ feet.

Value of K	Ratio of energy absorbed to energy in tup immediately before fracture $1 - K^2$	Error in energy measurement $\delta = 1$ per cent. Per cent.	Error in energy measurement $\delta = 4$ per cent. Per cent.
0.2	0.96	0.25	0.93
0.4	0.84	0.66	2.50
0.6	0.64	1.5	5.8
0.8	0.36	4.3	16.5

With lower falls (H) the error is somewhat greater, with higher falls it is somewhat lower. It is obvious, therefore, that K should not exceed 0.5 in order that the error in the energy measurement should not exceed the error in the time measurement; that is, the velocity after impact should not be greater than half the velocity immediately before impact.

---

*This investigation was made by Capt. C. E. P. Sankey, R. E.

Storage of Benzin

The increasing use of benzin as motive fluid for automobiles, motor boats and self-propelled dirigible airships—to say nothing of its employment as a solvent of india rubber, and its use as a menstruum for paints—makes anything tending to diminish the undoubted danger attending its storage and use of special interest. The liquid in question is, as all know, "water white"; but all do not know that its boiling point lies at from 105° C. = 221° F. down to as low as 80° C. = 176° F. Just what "benzin" is depends very much on the custom of the trade on the one hand, and the orders of the petroleum refiners on the other, for other products that pay better. The flash-point of this liquid, as ordinarily known in the automobile branches of industry, is about 21° C. = 69.8° F. The danger attending its use arises, not from its low flash-point, but from the fact that with air it forms an explosive mixture, when present in quantities lying between 2.8 and 4.4 volume per cent.

In 1893 Richter made a number of experiments as to the explosibility of this material, and found that up to that time its unexplained spontaneous ignition was due to its electric excitability. By the addition of salts of oleic acid (antibenzinpyrin) this danger was done away with. In 1899 the Society for Vessels that are Safe from Explosions, Salzkotten, produced vessels surrounded by wire gauze, so as to act on the principle of the Davy lamp, and the employment of such receptacles enables pouring benzin or other similarly explosive fluids into the fire without an explosion taking place. These receptacles are not, however, safe against lightning.

By filling one vessel with benzin from another, by means of compressed air, many explosions have been caused. To do away with this danger it has been recommended to use cold gaseous products of combustion. A further step in the direction of safety was made by the use of carbonic acid gas to produce the required pressure. According to Prof. Lunte, the addition of only 12 to 13 per cent. of this gas to an explosive mixture of benzin and air will render it harmless. One form of apparatus for storing and handling benzin has a tank for the benzin and a vessel of compressed carbonic acid gas; and between them a safety chamber buried in the earth.

Another safety arrangement, that of Grümer & Grimberg, in Bochum, permits the use of compressed air as a medium of transfer. It consists of a riveted boiler-plate receptacle, which is always out of the reach of fire (being buried in the earth), and from which the benzin is forced into the smaller vessels to be filled, by throwing into the connections a supply of compressed air. There is a steel tank of compressed carbonic acid, from which the gas is forced under very slight excess of pressure into all part of the piping and receptacle, so that the development of an explosive mixture of benzin vapor and air is impossible. An automatic safety appliance renders impossible any false arrangement or handling of the apparatus by carelessness. The quantity of carbonic acid gas necessary is very slight. An excess of pressure of one-tenth of an atmosphere is sufficient to insure the entrance of the gas into all parts of the piping and that part of the main receptacle not filled with benzin.

Automobile Accidents and "Autlers"

GERMANY has for some time past kept statistics concerning the number, kind and cause of automobile accidents, and results show that a large proportion of these—some of which were very severe—were due not to the speed at which the car was traveling, but to the foot passengers or others who were injured. Regierungsrat Dr. Haaselau had an article in *Der Tag*, of Berlin, calling attention to the almost incredible carelessness of foot passengers in regard to motor cars, and further, to a group of accidents in which the occupants of the car were injured and the driver alone was to blame, not by reason of speed, but because of his incapacity. There are drivers—both car owners and employees—with whom one feels absolutely safe at 60 miles an hour, and who have never had an accident.

As a parallel case, the author cites a second-class trapeze "artist," who would attempt to perform first-class feats, but who would be in constant danger of his life, because his physical elasticity was not equal to doing that which a first-class performer would easily perform. It is the same thing with motorists. Besides technical education, natural ability or adaptability, presence of mind and good nerves are of great importance as regards the degree of perfection or skill in handling a motor-car. There are drivers who can direct a car at 20 miles an hour with perfect skill, and at that speed are perfect masters of the situation, but as soon as they increase the speed in any degree are unsafe, and in a tight place they funk.

"How is this evil to be done away with?" inquires Dr. Haaselau. To do this by police regulations, setting a limit to the speed at which any given driver may conduct his car—as is the case in many towns in England—is impracticable. For instance, in many cases the limit is set at a point corresponding to the average ability of the drivers, namely 10 miles per hour, which reduces the whole ability of the automobile to that of the horse-driven vehicle. This completely shuts out the possibility of the use of the car in such towns.

Dr. Haaselau is of the opinion that better education and more experience should be demanded of the driver. The existing schools have, with few exceptions, no interest other than to turn out the maximum number of "chauffeurs" in as short a time as possible. They assume no responsibility for the subsequent performance of their pupils. Even the testing of their capabilities by experts offers no security, being not sufficiently thorough, and largely dependent on chance. The "chauffeur's" training should take place in schools having no pecuniary interests in turning out drivers, and should be, if possible, conducted by the municipal authorities, so that the official examination could take place at the end of each course.

Here unsuitable elements could be weeded out in time. The pupils would also be taught the dangers of high speeds. Drivers from such schools would naturally have the preference among car owners, and the time would come when none but such would be employed.

Imports of Automobiles Into Russia

The importation of vehicles of all kinds into Russia increases each year. In 1906 the total value was only 1.8 million roubles; 1907, 3.5 millions; 1908, 5.1 millions. This development is principally due to the growing demand for automobiles. In 1904 and 1905 the importation amounted to only 100,000 roubles each; in 1907, however, 1.6 million, and in 1908 to 3.1 million roubles. Preference is given to large cars with four to six seats. Of these, in 1908, there were 2.8 million roubles' worth bought abroad; of the smaller ones, only 0.3 million. The Russian automobile manufacturers have made only slight progress in 1908. Most of the work in this line consists in assembling parts bought abroad, and in the "carosserie," or carriage-making proper. These factories have, however, but limited custom. For expensive cars only French makes are preferred, while the German ones are taken for heavy passenger cars and for omnibuses. But the German manufacturers are making every effort to push the sale of their more expensive makes in Russia. In the automobile races, which take place once in a while, most of the cars are German. That they are better suited to the miserable Russian roads than the French has been shown by the recent races between St. Petersburg and Riga. The increasing importance of Russia as a market for automobiles has also brought American manufacturers on the scene. These strive specially to push the sale of the cheaper sorts, but by reason of their cheapness, says the German consul in St. Petersburg, they do not appear to be very desirable.

Coming Events in the Automobiling World

Dec. 1	Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.
Jan. 7-14, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Automobile Manufacturers.
Jan. 16-21, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Jan. 28-Feb. 4, '11	Chicago Coliseum, Tenth Annual National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Pleasure Cars and Accessories Exclusively.
Feb. 6-Feb. 11, '11	Chicago Coliseum, Tenth Annual National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc. Commercial Vehicles, Pleasure Cars, Motorcycles and Accessories.

Races, Hill-Climbs, Etc.

July 18-23	Milwaukee, Wis., Tour of Wisconsin State Automobile Association for Milwaukee Sentinel Trophy.
July 22	Atlanta, Track Meet, Atlanta Automobile Association.
July 23	Brighton Beach, Track Meet, Motor Racing Association, New York City.
July 25-26-27	Cleveland, O., Reliability Run, Cleveland, Ohio, News.
July 25	Chillicothe, O., Track Meet, Chillicothe Order of Owls.
July 30	Wildwood, N. J., North Wildwood Automobile Club, Speedway Races and Club Run.
July 30	Long Island Motor Parkway, Track Meet.
Aug. 1	Minneapolis, Minn., Reliability Run of Minneapolis Automobile Club.
Aug. 3-5	Galveston, Tex., Beach Races, Galveston Automobile Club.
Aug. 11	Algonquin, Ill., Annual Hill Climb of Chicago Motor Club.
Aug. 16	Start of Munsey Tour.
Aug. 17	Cheyenne, Wyo., Track Meet.
Aug. 31	Minnesota State Automobile Association's Reliability Run.
Aug. 31-Sept. 8	Kansas City, Mo., Reliability Run, Auto Club of Kansas City.
Sept. 2-5	Indianapolis, Ind., Speedway Meet.
Sept. 3-5	Labor Day Race Meet of North Wildwood Automobile Club.
Sept. 5	Wildwood, N. J., Track Meet.
Sept. 17	Syracuse, N. Y., Track Meet of Automobile Club of Syracuse, Syracuse Automobile Dealers' Association and the New York State Fair Association.
Sept. 24	Santa Monica, Road Race, Licensed Motor Car Dealers of Los Angeles, Cal.
Sept	Chicago, Commercial Car Reliability Contest of Chicago Automobile Club.
Oct. 1	Long Island Motor Parkway, Vanderbilt Cup Race, Wheatley and Massapequa Sweepstakes.
Oct. 3	Louisville, Ky., Reliability Run, Louisville Automobile Club.
Oct. 6-8	Santa Anna, Cal., Track Meet.
Oct. 7-8	Los Angeles, Cal., Speedway Meet.
Oct. 8	Philadelphia, Fairmount Park Race, Quaker City Motor Club.
Oct. 15	Long Island Motor Parkway, Grand Prize, Automobile Club of America.
Oct. 15-18	Chicago, Ill., Chicago Motor Club's 1,000-Mile Reliability Run.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

TO enable the user of pleasure cars or of trucks to get along with a small motor and yet have power for emergencies is the object of many experimental efforts among the designers of Europe to-day, and this trend toward economical refinement in automobile motors goes side by side with the bold departures from current practice which are witnessed in the aviation field. Other things equal, the most economical power must eventually prevail here as well as in less favored countries, and for this reason, if for no other, the brief accounts of Europe's feverish experimentation recorded weekly in our Extracts from Foreign Papers, claim the attention of the provident manufacturer. They should help to anticipate and forestall unpleasant commercial surprises. Refinement in constructive thought is Europe's strong point, and eventually there must be a reckoning, once more, between the merits of its practical results and those of our eminently successful refinement in the methods of mass production.

* * *

PREPARATION is rapidly going forward for the great meeting of the automobile engineers, which is to be held at Detroit, on July 28, 29 and 30. Indications point to a large program; many papers will be read, and knotty points will be aired. In addition to these important matters, there will be visits to plants, entertainment of the instructive sort, and, in addition, the great question of standardization of the materials used in automobiles will be earnestly debated. The Society of Automobile Engineers, while it is assured of a full attendance of its large and growing membership, has invited all automobile men to go to Detroit and participate in the doings—a welcome is assured, nor is it necessary to await further invitation. Go to Detroit; have a vacation and enjoy three days of automobile reviewing; even take part in the discussion and add a mite to the progress to be made.

* * *

FORTUNATE to relate, almost every autoist becomes acquainted with his car and its workings, excepting the ignition system, in a very short time. The electrical part of the equipment gives him sleepless nights; nor does he make any effort to cast off the hypnotic spell. There is nothing about an electric system that cannot be mastered by almost any autoist within a few days, and it is too bad that it is not given more attention and a little better care. When a man decides that he does not understand a thing, his inclination is to let it alone, and when an electrical device is neglected, the chances are that it will go awry.

* * *

FANCY free, with money in hand, the man with a penchant for real enjoyment, purchases a good automobile and goes forth to conquer. This is as it should be, and the money expended in enjoyment of this form is actually invested on a dividend paying basis. But this is not all; piano-forte makers are now complaining that even on the pay-as-you-please plan for a more or less good instrument, women are just a little timid—a natural inclination with them—and it is claimed that the automobile pleases them more; being used to having their own way, they get what they think will be of the most benefit, and as men of any wisdom will testify, a woman's judgment is rarely ever far wrong.

* * *

MUSIC and its charms are accompaniments of life that can ill be dispensed with, but it is not believed that it is better to possess a cheap piano on the installment plan than it is to purchase an automobile for cash, and with it learn of the beauties of nature, and fill the lungs with life-giving oxygen. As an economic proposition, should pianos be peddled on the installment plan? Is it economical, speaking in the broader sense, to purchase musical instruments on the installment plan? Is it not better to buy automobiles for cash?

* * *

AGITATION nearly always has the misfortune to be one-sided. The financiers, for illustration, who are so fearsome about the money that is being utilized profitably in automobile work, type their logic and send it forth, hoping that they are the only ones who know how much they need the money in their own enterprises. But they can only imitate that bird of gay plumage, the ostrich, hiding the head of their tale in the sand of piercing public gaze. The real question is, Can these agitators present as sound an investment, and do they offer the future with all its security that the automobile presents? The record of the automobile industry is clean; no battery of telephones was ever used in a "thimble rigging" process to bolster it up. It requires no such support. How about the methods of the interests that are decrying the automobile? Are their escutcheons without a splash of the blood of murdered enterprises?

New York State in Throes Due to Callan Law

CHAUFFEURS, of whom there are upwards of 35,000 in New York City and vicinity, are being introduced to the intricacies of the new Callan law. The Secretary of State, through his publicity agent, has been leading the public to believe that chauffeurs would be given a regular and comprehensive examination under the direction of a corps of capable examiners headed by a chief examiner whom the public could rely upon in every particular. To what extent the Callan law is a good one remains to be seen. The autoing public, however, assumes the attitude of a "first night" audience. In some respects the situation does not look promising; there are but a few days available for the examination of chauffeurs, and up to the present time but a small proportion of them have been accommodated.

* * *

JUDGING by the character of the publicity which is alleged to emanate from the office of the Secretary of State, a chauffeur is a man who must be fettered. It was said that a rigid examination would be instituted, and that the chauffeur of no competence and small respect for law would be eliminated. As it stands at the present time, it would be impossible to give a comprehensive examination to the chauffeurs were they to apply for same and appear, as they have a right to, within the few fleeting days before the law dates to go into effect. If the Secretary of State is trying to "mould" public opinion, and if he thinks it can be done by flooding the press with hollow publicity, it is feared that the average autoist has enough civic intelligence to permit of generously disagreeing with him.

* * *

FAIRNESS demands more than criticism, and the idea that Senator Callan is a mere "chestnut puller" must include the assumption that he hopes to please such of our citizens as are afflicted with a disease called "Autophobia," and that he thinks the rest of the public is so dull that it will be herded to the polls by the "machine" despite the fact that the users of automobiles in the State of New York will have to pay $2,000,000 for the privilege, which, according to Governor Charles E. Hughes, is the size of the hole in the budget that autoists are expected to stop up. This is scarcely possible.

* * *

CHARITY, with its broad mantle, is said to be sufficient to cover a multitude of sins, and assuming that it has the characteristics of caoutchouc, it may be utilized to advantage in the further effort involving the Callan Act. How this mantle will be rendered sufficiently expansive, however, to hide some of the defects of this law is the problem which confronts plain citizens. Quite a few autoists would like to know by what constitutional right legislative power can be delegated to the Secretary of State. Under the Callan Act chauffeurs must be licensed by the Secretary of State, but the methods involved in the process of licensing this class are not prescribed in the law itself, but the Secretary of State is empowered (according to this law) to prescribe conditions. It is left to him to arbitrarily establish the qualifications that shall be required. Is this not legislative power?

* * *

IT is prescribed in the new law that no new licenses shall be granted where one has been suspended or revoked, unless the discretion of the Secretary of State authorizes it. Does the Secretary of State get his right to legislate (as here indicated) by virtue of "Senator" Callan's 25-year-old acumen? According to this law, and the interpretation alleged to be put upon it by the Secretary of State, no license will be issued to a driver of known recklessness. Why should the taxpayers of New York support a large body of respected Justices if it is no longer necessary to try a man for an offense and convict him by due process of law? When did the Legislature acquire the right to manufacture retroactive law?

* * *

TAKING up the question of fees, they are graduated according to horsepower in lieu of all taxation. Did the "Senator" in his desire to work into the good graces of his constituents overstep the bounds? Does he think it is constitutional to exempt automobiles and not exempt other vehicles?

* * *

DOES the "Senator" think that autoists will appreciate the exemption from taxation as it is written in the law? True, the automobile is exempt from taxation, but the cost of the exemption clause is $2,000,000. Is the "Senator" worth $2,000,000 a year to the owners of automobiles in the State of New York? It would be interesting to hear from a few thousand more autoists on this point, or, better yet, it would be worth knowing just how liberal they do feel. Certainly they can find no ground for assuming that the "Senator" may not ultimately give them another exemption at a cost of $2,000,000 more.

* * *

WHEN the new law was framed, and the claim was made that drivers of automobiles should be compelled to indicate that they are capable, if the foundation of the new law was fundamentally right, was it not a fair inference that the examiners should show their capability before they were licensed to examine? Can the blind lead the blind? Are the people of the Empire State likely to receive any additional protection from reckless chauffeurs through an examination conducted by examiners who are not required to pass an examination themselves? Would it not be just as reasonable to appoint bartenders as examiners, or men who are quite familiar with the inner workings of a jail, as it is to make political appointments to fill the examiners' chairs, when, as a matter of fact, the examination to be of any value must be technical?

* * *

WHEN the necessity arose for a revision of the law as it related to the automobile, the politicians who had the matter close to their hearts voiced a sentiment which sounded like sweet music, contending that the fees for licensing should be dissolved in road building. Every autoist knows that a good road is a money-maker for him, that if the road is in a bad state of repair his automobile will catch the disorder just as smallpox spreads through an improvised camp, and with one accord the automobile users, backed by the manufacturers, supported the issue. They could not have foreseen that any politician would be so shortsighted as to abandon a good position and go the length of transferring the money returns to the General Budget, thus destroying every reason for worming cash out of a man's pocket simply because he rides in an automobile.

* * *

GOOD roads are recognized as a necessity, not only for the automobile, but for every other vehicle as well. The farmer knows the value of a good road leading from his front door to the market square in the nearest town, and the modern farmer finds it to his advantage to resort to methods of "intensive cultivation," which methods are incomplete in the absence of "intensive transportation." The modern farmer shows by his progressive acts that he knows these things, but it is a question if the lawmakers have kept pace with progressive farmers, and it is believed that the framers of the Callan law, instead of pleasing the farmers and hoodwinking the rest of the people, have pleased no one, and it remains to be seen if they can hoodwink any one.

A. L. A. M. Files Decree in Long-Pending Selden Suit

Judge Charles M. Hough Acts in Favor of Complainants

Ford Lawyers Contend for Bond Rather than Injunction

A TENTATIVE decree covering the salient points in the opinion rendered by Federal Judge Charles M. Hough in the suit of George B. Selden and the Columbia Motor Car Company, exclusive licensee under basic patents granted to Mr. Selden for improvement in road engines, was filed with Judge Hough July 19 in the parlors of the New Mathewson Hotel at Narragansett Pier.

The decree submitted was that drawn by Frederick P. Fish and Samuel R. Betts on behalf of the complainants and under its terms the Columbia Motor Car Company is installed formally as party complainant to the suit and substituted for the Electric Vehicle Company, which instituted the action. It holds that George B. Selden is the legal inventor of the gasoline road engine and that the defendants, the Ford Motor Company and C. A. Duerr and Company, representing the Panhard Motor Company, had been guilty of infringing sections 1, 2 and 5 of the letters patent.

It holds that the complainants are entitled to recover the profits, gains and advantages that have accrued to the defendants by reason of the infringements and orders the whole matter to be reported to a Master of the Court to take account of the measure of damages that shall be taxed.

The decree also provides that a perpetual injunction issue against the defendants, prohibiting them from continuing to infringe the patents.

Besides Messrs. Fish and Betts, George B. Selden and Alfred Reeves appeared on behalf of the complainants and Edmund Wetmore, W. Benton Crisp, Frederick R. Coudert, James Cousins and Charles K. Offield represented the defendant companies.

The question of issuing an injunction was sharply contested by the defendants, who asserted that if an injunction was to issue pending an appeal of the cause to the Federal Court of Appeals, a substantial injustice would be worked to the interests of the 4000 men employed by the Ford Motor Company with its big factory and seventeen branch houses. It was urged that the defendants were quite as anxious as the complainants to bring the matter to a final decision, and for that reason the suggestion was made to the Court that a sufficient bond to cover damages and profits might better be required pending such final decision.

Complainants' attorneys in discussing this phase of the matter mentioned the figures of $500,000 as the size of the bond to be filed by the Ford Company and $50,000 by the Panhard Company.

Whether the issuance of such an order will be made is problematical and will not be known in the immediate future because the decision of Judge Hough as to the exact form of the decree is still under advisement.

The Court is in vacation at present and Judge Hough was visiting Narragansett Pier for the purpose of addressing the Sixteenth Annual Convention of the Commercial Law League of America.

The proceedings of the case will come up for final review and an ultimate decision in October before the Court of Appeals. A preferential position for the matter has been secured on the calendar of that Court.

The full text of the decree submitted follows:

At a stated term of the United States Circuit Court for the Southern District of New York, held in and for said district on the Nineteenth day of July, 1910. Present Hon. Charles M. Hough, Judge. The Columbia Motor Car Company and George B. Selden, Complainants. vs. C. A. Duerr & Company and Ford Motor Company, Defendants. In Equity No. 8566 On Selden Patent No. 549,160.

This cause having come on for final hearing upon the original pleadings, and the proceedings, and the testimony and the proofs filed on behalf of both parties, and having been orally argued before the Court on the issues raised by said pleadings and proofs on the 28th and 29th days of May and the 1st, 2d, 3d, and 4th days of June, 1909, by Frederick P. Fish, William A. Redding and Samuel R. Betts, counsel for complainants, and R. A. Parker and W. Benton Crisp, counsel for defendants, and an opinion herein having been filed by His Honor, Judge Hough, on September 15, 1909, and this cause thereafter having come on to be heard on the supplemental bill and answer and replication, and the proceedings, and the testimony and proofs thereunder, filed on behalf of both parties, and having been orally argued before the Court on the issues raised by said supplemental pleadings and proofs, on the 19th day of July, 1910, by Frederick P. Fish and Samuel R. Betts, counsel for complainants, and Edmund Wetmore and W. Benton Crisp, counsel for defendants, now, after due proceedings had, it is, upon consideration, ordered, adjudged and decreed as follows:

1. That the Columbia Motor Car Company, as an assignee of Electric Vehicle Company, be and is hereby made a party complainant to this suit in the place and stead of said Electric Vehicle Company, and is hereby given the same benefit of the record and proceedings herein, and of any decisions, orders or injunctions heretofore or which may hereafter be granted against the defendants herein, as the said Electric Vehicle Company, or its Receivers, or either of them might have had, if they had not made the assignments dated June 30, 1909, to said The Columbia Motor Car Company. That the said the Columbia Motor Car Company is hereby authorized to continue the prosecution of this suit with George B. Selden, patentee of the letters patent proceeded on herein, against the defendants, as of the 30th day of June, 1909, and as a complainant therein in the place and stead of said Electric Vehicle Company.

2. That the letters patent of the United States issued to said George B. Selden on November 5, 1895, No. 549,160, for Improvements in Road Engines, are good and valid in law as to the first, second and fifth claims thereof, being the claims proceeded on in this cause, and which are as follows:

> "1. The combination with the road-locomotive, provided with suitable running gear including a propelling wheel and steering mechanism, of a liquid-hydrocarbon gas-engine of the compression type, comprising one or more power cylinders, a suitable liquid fuel receptacle, a power shaft connected with and arranged to run faster than the propelling wheel, an intermediate clutch or disconnecting device and a suitable carriage body adapted to the conveyance of persons or goods, substantially as described.
>
> "2. The combination with a road-locomotive, provided with suitable running gear, including a propelling wheel and steering mechanism, of a liquid-hydrocarbon gas-engine of the compression type, comprising one or more power cylinders, a suitable liquid fuel receptacle, a power shaft connected with and arranged to run faster than the propelling wheel, an intermediate clutch or disconnecting device and a suitable carriage body located above the engine, substantially as described.
>
> "3. The combination with a road-locomotive provided with a propelling wheel, of a liquid-hydrocarbon gas-engine of the compression type, comprising two or more working cylinders and pistons arranged to act in succession during the rotation of the power shaft, a suitable liquid fuel receptacle, suitable devices for transmitting motion from the power shaft to the driving axle, and a clutch or disconnecting device, substantially as described."

3. That the said George B. Selden was the sole, first and original inventor and discoverer of the inventions described in said Letters Patent, and claimed in the said first, second and fifth claims thereof.

4. That the said George B. Selden, complainant, is the owner of the legal title to said Letters Patent, and that the complainant, The Columbia Motor Car Company, is the exclusive licensee thereunder, with power to grant sub-licenses.

5. That the defendant Ford Motor Company has infringed upon the said Letters Patent and said claims 1, 2 and 5 thereof, and upon the exclusive rights of complainants under the same, by manufacturing, using and selling, in the United States, within the Southern District of New York and elsewhere, without right or license, road engines, vehicles or gasoline automobiles containing, embodying or employing the said inventions and improvements described in said Letters Patent and claimed in the said first, second and fifth claims thereof; and that the defendant, C. A. Duerr & Company, has infringed upon said Letters Patent and the said claims 1, 2 and 5 thereof, and upon the exclusive rights of complainants under the same, by using and selling in the United States, within the Southern District of New York and elsewhere, without right or license, road engines, vehicles or gasoline automobiles containing, embodying or employing the said inventions and improvements described in said Letters Patent and claimed in the said first, second and fifth claims thereof.

6. That the complainants do recover of the defendants the profits, gains and advantages which the said defendants have derived, received or made by reason of the said or any infringement by the said defendants of said claims 1, 2 and 5 of the said Letters Patent; and that the said complainants do also recover of said defendants any and all damages the complainants or their assignors may have sustained by reason of any infringement of said claims of said Letters Patent by the defendants.

And it is hereby referred to a Master of this Court (who is hereby appointed for the special reason to take and state an account of such gains, profits and advantages, and to assess such damages, and to report to the Court thereon with all convenient speed. And the defendants and each of them are hereby directed and required to attend before said Master from time to time as required, and to produce before him such books, papers and documents as relate to the matters at issue, and to submit to such oral examination as the Master may require.

7. That a perpetual injunction issue out of and under the seal of this Court enjoining and restraining the defendants and each of them, and their and each of their officers, directors, associates, attorneys, solicitors, clerks, servants, agents, employees and workmen from directly or indirectly making, or causing to be made, using, or causing to be used, or offering or advertising for sale, or causing to be offered or advertised for sale, or importing or causing to be imported, or selling or causing to be sold in any manner, or disposing of in any way, within the United States, any road-engines, vehicles, automobiles, devices or apparatus containing or embodying or employing any of the inventions described in said Letters Patent and claimed in said first, second and fifth claims thereof, or substantial or material parts thereof, or from infringing said claims of said Letters Patent in any way whatsoever.

8. That the complainants do recover of the defendants their costs and disbursements in this suit, to be taxed by the Clerk of this Court, and that the question of increase of damages and all further questions be reserved until the coming in of the Master's report.

Jersey May Hold Up Tourists as Reprisal Act

MEASURES of reprisal which have been adopted by several States adjoining New Jersey against that State on account of the Jersey statute that makes it obligatory for touring automobilists who venture wheel upon the sacred soil of the Garden State to take out a license or suffer the various penalties provided by law for just such cases, have aroused Jersey automobilists to a pitch they have never reached before.

The feeling against the State of New Jersey on account of the stringent road law has taken concrete shape in Pennsylvania and New York. In Pennsylvania, particularly in the city of Philadelphia, the status of the visiting Jersey motorist is unpleasant. No sooner does a touring Jerseyite enter Philadelphia than he is arrested if he has no Pennsylvania permit. What makes the Jersey citizens froth at the mouth about this procedure is the fact that any car bearing a New York license is not disturbed in any way in Pennsylvania.

Only recently a fine example of how this practice works was afforded by a case in Philadelphia. A New York tourist who had been spending some time in Jersey and who was equipped with a State license of that State crossed the ferry and started up Market street. He managed to get three blocks before the watchful officers spied the triangular license tag and descended upon him.

Up to the City Hall he was taken by the police and a fine as well as payment of the Pennsylvania license fee seemed certain. The prisoner protested that he was a New Yorker and had a New York license. The police asked to be "sighted," and when the prisoner produced the New York permit he was instructed to remove the Jersey license and replace it with that of New York. This was done and the prisoner and car were released with the injunction to go as far as they liked.

It is such instances as the one recounted that get on the nerves of Jerseyites.

Last winter an amendment to the automobile law was passed making it possible for non-resident tourists to secure touring licenses in New Jersey for a period of eight days during one year. These permits may be withheld in the discretion of the commissioner, and such action is being contemplated against automobilists of Pennsylvania and other States in which Jersey owners come afoul of the law. The action with regard to Jersey on the part of Pennsylvania is similar to the recent attitude taken against Maryland.

Twenty-Four Start in Wisconsin A. A. Run

MILWAUKEE, WIS., July 18—Twenty-four cars were sent on their way at 7 o'clock this morning for the first annual reliability competition of the Wisconsin State Automobile Association for the $800 Milwaukee *Sentinel* trophy. In addition, there were five official cars, the 1911 Peerless acting as pacemaker.

The contestants are:

No. Car	Entrant	Driver
1—Rambler	Rambler Garage Co.	Edward Collier
2—Rambler	Rambler Garage Co.	Art Gardiner
3—Badger	Badger Motor Car Co.	E. W. Arbogast
4—Badger	Badger Motor Car Co.	H. A. Arbogast
5—Mitchell	Mitchell Auto Co.	F. P. Wilkins
6—Cadillac	Jonas Automobile Co.	Aug. A. Jonas
7—Jackson	W. L. McEldowney	W. L. McEldowney
8—Buick	Buick Motor Co.	Wm. Fisher
9—Buick	Buick Motor Co.	
10—Kissel	The Kissel Kar Co.	N. C. Rice
11—Kissel	The Kissel Kar Co.	W. R. Rice
12—Kissel	The Kissel Kar Co.	Arthur Ove
14—Pierce-Racine	Morrison Motor Car Co.	Lewis Strang
15—Johnson	Johnson Service Co.	J. W. Eviston
16—Ohio	Case Plow Works	Ross Neuwood
17—Pope-Hartford	Emil Estberg	F. L. Buckbear
18—Reo	Curtis Auto Co.	E. H. Thomas
19—Corbin	Curtis Auto Co.	Gordon Bird
20—Ford	Hickman-Lanson-Diener Co.	W. H. Diener
21—Franklin	Franklin Auto & Supply Co.	M. E. Springer
22—Overland	Bates-Odenbrett Auto Co.	John Heber
23—Staver	Stephenson Motor Car Co.	Chester Cheney
24—Petrel	Petrel Motor Car Co.	G. D. Waite
25—Marion	Geo. Browne	Geo. Browne

The route of the tour covers a distance of 808 miles, including practically every section of the State of Wisconsin within a sweeping circular course. The night stops will be at Madison, the State capital; La Crosse, Eau Claire, Merrill and Appleton. David Beecroft, of Chicago, is chairman of the Technical Committee.

Secretary Elliott Makes Denial

"Have never, in any position which I have held, criticised my superior officer."

State Troops to Guard Elgin Road Race Course

CHICAGO, July 19—The Chicago Motor Club and Elgin Automobile Road Race Association, which are promoting the road races at Elgin, Illinois, on Friday and Saturday, August 26 and 27, to-day secured military protection when the services of the Fifth Regiment of the Illinois National Guard were promised by Colonel Frank S. Wood, the officer in command. The Fifth will furnish between 200 and 300 men, plenty to guard a nine-mile course. The contractors are busy on the course at the present time and next week the trophy question will be settled.

The Chicago Motor Club also announced to-day that the annual Hill Climb at Algonquin, will take place August 11 instead of August 4 as first intended. The club has been obliged to give a $20,000 bond to protect Dundee County, in which Perry Hill is located. Entry blanks are now out.

Franklin Branch Managers Meet

SYRACUSE, N. Y., July 18—The branch managers' convention of the Franklin Automobile Company was held this week, beginning Wednesday and closing to-day. There are 13 Franklin branches—the concern finds 13 a lucky number—and Boston and 'Frisco and much intermediate territory were represented. J. E. Walker presided and S. E. Ackeman was secretary.

The district managers present were: J. F. McLein, San Francisco; S. N. Lee, Albany; F. H. Sanders, Rochester; George E. Messer, Syracuse; H. T. Boulden, Cincinnati; C. H. Rockwell, Cleveland; F. L. Thomas, Chicago; George Ostendorf, Buffalo; E. W. Orr, Buffalo; A. B. Henley, Boston; W. F. Reynolds, Pittsburgh; W. S. Jewell, New York, and W. E. Brearley, St. Louis. The salesmen present included R. H. Laporte, Glenn A. Tisdale, L. E. Hoffman, J. L. Wetherby, D. F. Garber, G. S. Ruhl and F. A. Babcock.

Matheson Creditors Believe in the Future of the Company

CREDITORS of the Matheson Motor Car Company, of Wilkes-Barre, Pa., which went into the hands of a receiver July 7, met at the Hotel Breslin Tuesday at the suggestion of the receiver to formulate some plan by which the life of the company might be insured.

The meeting was attended by 52 creditors, representing a majority of the claims both in number and amount. E. C. Fretz, of the Light Manufacturing & Foundry Company, of Pottstown, presided.

The purpose of the meeting was outlined by several of the speakers. They said that it was their wish to arrive at some plan by which the receivers might be discharged as soon as possible, both for the sake of the creditors and for the company itself. The fact was emphasized that the assets of the company showed $262,000 more than the liabilities, and that a little time would develop whether or not the company would be able to rescue itself.

C. W. Matheson was called upon to outline present conditions and said that at the time the receiver was appointed the company had valid contracts upon its books for the sale of 228 cars of a wholesale value of over $600,000.

That sum would be sufficient to wipe out the claims, according to many of those who attended the meeting.

The underlying reason for the difficulty in which the Matheson company finds itself is the weather that obtained throughout the country last Spring, particularly in the Middle West. There were two months of unseasonably cold weather, followed by six weeks of rain, and the result was that automobile dealers who contracted for cars from the factory and made the usual deposits upon them were unable to make deliveries to their customers because of the bad weather. Few purchasers of cars care to give them their initial try-out in a driving rainstorm or at a time when ear-muffs and bearskin gloves are necessary. As a consquence, even where dealers had closed with purchasers, there was much delay in placing the cars.

The four chief creditors of the Matheson Motor Car Company are the Light Manufacturing & Foundry Company, the Bosch Magneto Company, the Diamond Rubber Company and the Reading Metal Body Company.

In naming a committee of creditors to investigate conditions and to act in harmony with the management of the company and the receivers, Chairman Fretz appointed himself, representing the Light Manufacturing & Foundry Company; G. J. Bates, of the Diamond Rubber Company, and J. C. Reiber, of the Reading Metal Body Company. The Bosch Magneto Company, although one of the heaviest creditors, did not seek a place upon the committee.

The meeting adopted resolutions of confidence in the company and the car, and endorsing any action that the committee may take.

The resolutions pledge co-operation with others in interest to devise ways and means for the speedy discharge of the receivers. The action of the creditors was unanimous in all material points covered by the meeting.

It was pointed out that a receiver is simply an officer of the Court, that all receiverships are costly, and that in case of the creditors securing the discharge of the receivers the business of the company could be vastly facilitated.

A reorganization of the corporation upon a larger basis of capital was clearly outlined in the proceedings.

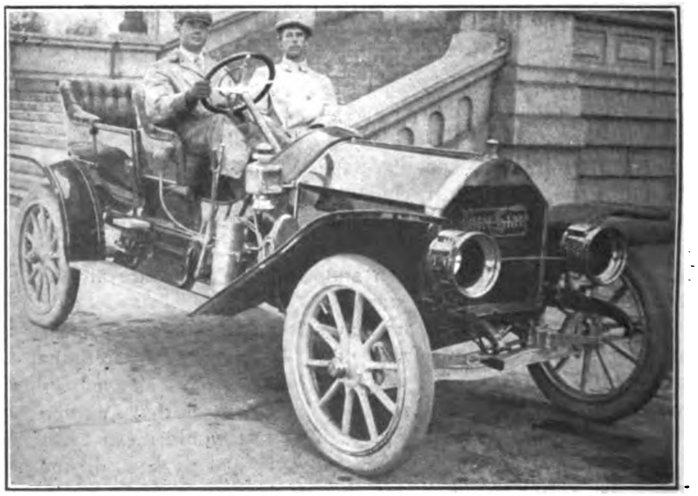
The Matheson Automobile Company, the selling company for the product of the factory, remains intact. Definite action on the part of the committee will probably take place in the immediate future and something in the nature of results is likely to develop in a month.

There was a distinct feeling of confidence apparent at the meeting.

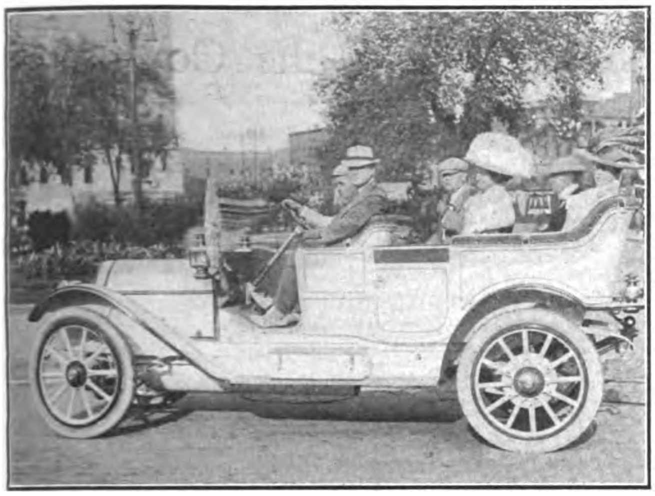
1911 Parry Models Increased in Number

With the broadening of the facilities at the Parry plant in Indianapolis the Parry Auto Company is bringing out eight 1911 models ranging in price as follows: $1,000 for Model 25; $1,300 for Model 43; $1,350 for Model 42; $1,500 for Models 37 and 39; $1,600 for Model 44, and $1,850 for Models 41 and 46. A certain amount of curiosity is evinced on the part of the auto-purchasing public, and, remarkable as it may seem, the old idea that the automobile is to be lowered in price marvelously in the course of time is vanishing. This range of prices for Parry automobiles, for instance, shows a certain stability. While the company offers a wider range of choices and a better value of equipment, it is holding its market tenaciously. Take the tire problem, for instance; the lowest-priced car, which is the roadster Model 25, has relatively large tires, considering the weight, but jumping to Model 39, which is the Combination Roadster, the tires are 34 x 3½, which, by the way, was originally stated in the advertised announcement of July 7 in THE AUTOMOBILE to be 36 x 3½. Obviously, the 34 x 3½ is a better proportion for this model. The Model 46, however, is fitted with 36 x 3½ tires and demountable rims.

President Taft used the White as an official car at the Fourth of July celebration in Boston



Up-to-date Inter-State in complete trim for touring ready for the ambitious owner to appropriate to his own use



Grand Exalted Ruler Sammis in the purple-and-white Chalmers "40" at the Elks Convention in Detroit

Chalmers "40" the Official Car at Elks Convention

Throughout the week of the national convention of the B. P. O. E. in Detroit—July 11th to 17th—Grand Exalted Ruler J. U. Sammis, of Iowa, attended to his official business in a 1911 Chalmers "Forty" touring car. This car was specially finished in white with purple striping and royal purple upholstering for the big Mogul of all the Elks. The driver wore a uniform of white with purple trimming.

Arch Hoxsey, the daring aviator, who occasionally does a little land traveling in his Cartercar

Daring Aviator an Accomplished Autoist

Arch Hoxsey, who is said to be the most daring operator of a Wright aeroplane, barring the Wright Brothers themselves, is also an enthusiastic automobilist. Last week his flights at Detroit were the most sensational ever witnessed in Michigan. While in Detroit Mr. Hoxsey drove a Cartercar, and is shown at the steering wheel with George Reason, branch manager for Cartercar, beside him.

Aviation News of the Week

OFFICIAL announcement of the terms and conditions of the aeroplane race from New York to St. Louis or from St. Louis to New York has been made. The New York *World* and the St. Louis *Post-Dispatch* offer a purse of $30,000 to the aviator who first accomplishes the feat under the rules, which are as follows:

The start shall be made some time between August 15, 1910, and January 1, 1911; the time limit is 100 consecutive hours and the entrant must use the same aeroplane throughout the trip. The only condition made by the donors of the rich prize is that three days' notice shall be given to either of the newspapers of intention to start.

The first announcement of the intention of the Pulitzer papers to hang up a big prize for a cross-country flight was made by Mayor William J. Gaynor, of New York, on May 31, this year, when he acted as spokesman for the donors at a banquet tendered to Glenn H. Curtiss after the completion of his flight from Albany to New York city.

Interest in the project was intense and immediate, not only on the part of the aviators themselves, but also in the public mind, both here and abroad. Glenn H. Curtiss is preparing to make the attempt as early as possible; the Wrights are completing an advanced type of racing machine; Clifford B. Harmon, the New York amateur; Charles K. Hamilton, who made the round trip from New York to Philadelphia recently; J. C. Mars, of Kansas City; Hubert Latham, Paulhan and Graham White are all considered more than probable starters.

Under the rules the aviators may select any routes they please and may stop as often as they like. It has been figured that traveling five hours during each of the four days allowed will prove sufficient sailing time to cover the 900 miles that intervene between the metropolis and St. Louis. That would mean a rate of at least 45 miles an hour, which has frequently been demonstrated as within the limits of the aeroplane. In order to remove the chance for technical disqualification that might exist if any binding system of elaborate rules were enforced, it is provided that the contestant himself shall be the judge of the start. If he finds after traveling any distance that his machine is defective, he may declare it "no start" as far as he is concerned, and may make another attempt.

British aviators and public have had their attention fixed for the past week on the Bournemouth meet, which has resulted in a series of distressing accidents, including the one which cost the Hon. Charles Stuart Rolls his life. One of the most sensational performances of the week was that of Robert Loraine, actor, who essayed to make the circle around the Needles, spindling rocks in the Solent. Almost from the moment of the start Loraine and his machine were enclosed in storm clouds, and before the actor had progressed to the outer mark he lost his way completely. With no idea of direction and unable to catch a glimpse of sea or land through the driving rain, the Thespian simply kept flying until his machine emerged from the storm and he was able to make a landing at Alum Bay, on the Isle of Wight.

Alan Boyle, son of the Earl of Glasgow, suffered a nasty fall with his monoplane, and at latest reports is hovering between life and death.

Count De Lesseps, who was the star performer at the aviation meet that closed Saturday at Toronto, made a high flight in his Blériot machine, scaling the air over 3,000 feet. On account of possible complications with the courts on account of the Wright injunction, the Frenchman will not perform in the United States for the present or immediate future.

Walter R. Brookins, who holds the world's record for high flight, gave an exhibition at Detroit Saturday in a gale that blew 25 miles an hour.

Plans for the International Aviation Tournament to be held at Garden City, L. I., in October are being made along unique and interesting lines. One of the main features of the meeting will be a sham battle in the air, in which European aviators wil be cast in the parts of the invaders, while the Americans take up the roles of defenders. A committee of aviator military men are preparing the details of the proposed

Matters of Interest to Boston Autoists

BOSTON, July 18—Motorists, who a few days ago believed that it would be an easy matter to convince the highway commission that the rule barring motor cars from the park system is a bad one, are not so sanguine that they can do so. The matter has taken on something of a political aspect, and the men who have watched the trend of affairs would not be surprised now if the commission approved the ruling, which would put it squarely up to Mayor Fitzgerald, of Boston. In other words, the highway commission may object to being used for political purposes.

As a result of what has developed there will be a lot of owners and dealers on hand when the hearing is held July 27 to protest against closing the roadways.

Secretary James Fortesque has sent out letters to the members of the Massachusetts State A. A.; the officers of the Bay State A. A. have taken up the matter also; the Boston Automobile Dealers' Association is to have a meeting to take action on the matter; the Automobile Legal Association officials have asked William A. Thibodeau to represent it at the hearing; and the National Automobile Association will be represented by Francis Hurtubis, Jr.

A number of individual motorists have already written letters of protest to the highway commission. It promises to be a lively hearing for the closing of the roads in the parks would mean sending motorists out of their way over rough and cobblestone roads coming in and going out of town every day.

An agency has been opened in Boston for the McIntyre truck. E. P. Blake, New England distributor of the Jackson and Fuller cars, has taken it on.

R. R. Ross has taken over the management of the Boston branch of the Fiat, while Simeon R. Baker, whom he succeeded, has moved down the street to the New England Motor Company, where he is now assistant sales manager, handling the Parry and Rainier cars.

W. S. Marsh, Boston agent for the M M motor cycles, has branched out, having taken on the Paige-Detroit for Boston and vicinity.

For the first time in some years motorists going to the south shore, found yesterday that they could go through Hingham, Mass., without having policemen jump out and get their numbers for prosecution, the traps there having been abolished. This was brought about by the newly formed Hingham Motor Club. This town was getting unenviable notoriety for arrests of motorists, and many owners avoided the place all Summer, making wide detours to cut it out.

So the club's executive officials took the matter up with Chief of Police W. I. James. After several conferences he stated that he would abolish the traps if the motorists will keep down to 15 miles in the congested part of the town, slow down and blow a horn at intersecting streets and use judgment in driving through the place.

However, he reserves the right to establish the traps again if necessary, so it is up to the motorists now. Members of the A. L. A., the Bay State A. A., and other organizations will be notified of the conditions and asked to co-operate to keep the traps eliminated.

United States Motor Co. Holds Annual Convention

Officers and representatives of the United States Motor Company and of its affiliated companies held their annual convention at Cedar Point, Ohio., July 11, 12 and 13.

The meeting afforded the first opportunity to bring together the combined sales forces of the Maxwell-Briscoe Motor Company and the Columbia Motor Car Company, although there were representatives from the other United States Motor Company plants and they manifested great interest in the methods and deliberations of the Maxwell and Columbia forces.

During the convention the many phases of activity in large selling organizations were discussed and after due consideration the policies and aims of the United States Motor Company were given emphatic expression. One of the matters which received unusual attention was the sales system and the supervisory organization by which the United States Motor Company will cover the entire country.

Among those present were: Benjamin Briscoe, president of the United States Motor Company; J. D. Maxwell, president of the Maxwell-Briscoe Motor Company; F. D. Dorman, vice-president of the Maxwell-Briscoe Motor Company; H. W. Nuckols, vice-president of the Columbia Motor Car Company; F. E. Dayton, sales manager of the Columbia Motor Car Company; Frank Briscoe, president of the Brush Runabout Company; Morris Grabowsky, general manager, Alden-Sampson Manufacturing Company; F. Harris, sales manager, Brush Runabout Company; J. I. Jameson, sales manager, Stoddard-Dayton Company; Charles E. Stone, commercial vehicle expert, Alden-Sampson Manufacturing Company. There were also the district managers, the branch house managers, and a number of dealers, as well as the advertising men of the United States Motor Company, Maxwell, Stoddard-Dayton, Brush and Columbia.

Officers, department heads and district managers of the United States Motor Company in conference with the officers, branch managers, sales and advertising managers of its affiliated companies, at Cedar Point, Ohio, July 11, 12 and 13

Hoosier Motordom in the Week's News

INDIANAPOLIS, IND., July 18—The next event at the Motor Speedway will be held September 3 and 5, instead of having a three-day meet, as at first planned. Approximately $10,000 in cash prizes will be offered, besides cups and medals, and an effort will be made to attract foreign drivers.

The principal event will be a 200-mile race on September 3. This will be open to all cars under 600 cubic inches piston displacement. First prize will be $1,000, second prize $500 and third prize $300. Other events will be the Remy Grand Brassard and Prest-O-Lite trophy races. E. A. Moross, director of contests, will go to Europe to secure the entries of several famous foreign cars and drivers for the meet.

A company which will manufacture gasoline trucks and other commercial vehicles is being organized in this city and will be incorporated with an authorized capitalization of $1,000,000. The concern will be known as the Great American Automobile, Auto Truck & Aeroplane Company. Temporary officers are: Samuel Quinn, Jr., president; John Feigen, vice-president, and A. J. Bigley, of St. Louis, Mo., secretary and treasurer.

Owing to a shortage of funds, the Indianapolis post office has been obliged to discontinue the 4 p. m. mail delivery in the business district. It is to be resumed immediately, however, and the four automobiles used for collecting mail will be utilized for delivering the mail in question in the business district, thus saving the salaries of several carriers.

Business men have organized the Greenfield Auto Traction Company, at Greenfield, and it has been incorporated with an authorized capitalization of $10,000.

The Fuller and Cutting agencies have been taken by the newly organized Auto Sales Company, which has taken temporary quarters in the Indiana Pythian Building. Douglas Case is president, M. G. Beckner vice-president, and Cass Connaway is secretary and treasurer.

Two Marmon and two Cole cars have been entered in the road race to be conducted by the Chicago Motor Club, August 26 and 27. It is expected other local cars will be entered later.

A. C. Newby, secretary and treasurer of the National Motor Vehicle Company, has gone to Europe for a six weeks' pleasure trip. He was accompanied by Mrs. Newby.

Issues Jersey Tags in Delaware

WILMINGTON, DEL., July 11—Charles G. Guyer, of 826 Market street, Wilmington, has been commissioned deputy motor vehicle commissioner for the State of New Jersey, in Delaware, with authority to receive license money and issue certificates and tags entitling the holders to use New Jersey roads. Mr. Guyer, who is secretary of the Delaware Automobile Association, was appointed by J. B. R. Smith, of Trenton, the motor vehicle commissioner for New Jersey.

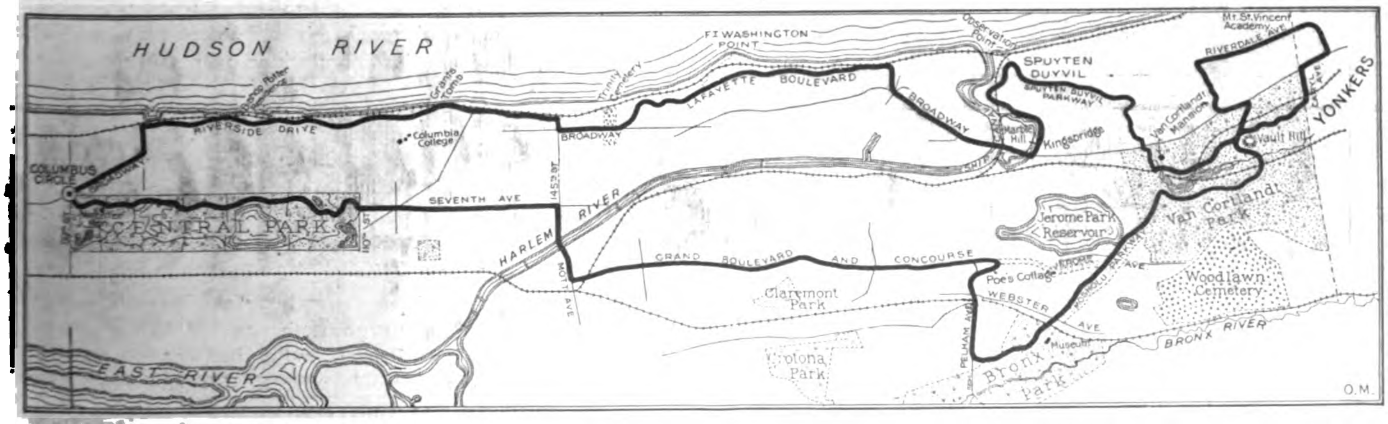
The establishment here of a New Jersey automobile license bureau is a great accommodation, not only to local machine owners and drivers, but also to those from other States passing through New Jersey from the South, as it enables them to pay the license and get the necessary tag and certificate here before crossing the Delaware River. If they were not afforded this accommodation they would have to hunt up a license bureau in Jersey or submit to arrest for failure to do so. In view of the fact that New Jersey requires a State license for every machine going there, this is a matter of interest to all non-residents living south of that State.

Near-by Motor Wanderings—Short in Length, Long in Interest

TO the New Yorker who knows not his New York, to the visiting motorist of an inquiring mind who would learn more of America's most important city and its environs, to the seeker after more than the mere delight of motoring on good roads—the new Metropolitan Automobile Guide will make especial appeal. Through the courtesy of its publishers, who are makers also of the Official Automobile Blue Book, we are enabled to present in full one of the many interesting routes comprised in its hundred round-trips from New York. The trip given below covers 30 miles of Metropolitan Wonderland, and is embellished with photographs of some picturesque spots en route, and a map showing the lay of the land. We make no doubt that many of our readers will avail themselves of the opportunity for trying out in advance the merits of this new Automobile Baedeker, which will be issued about August 10.

An illuminating example of the Baedeker feature of the new Metropolitan Automobile Guide, with special reference to the autoist to whom time is an object, but who is yet sufficiently awake to the interest and beauty of tours to points of historic value or scenic delight as to yearn for something different from the commonplace.

Route No. 211, New York to Yonkers line and return, is one of New York's choicest drives—of great scenic and historic interest, passing many spots of Revolutionary memory, going via Riverside Drive and Riverdale avenue, returning via



Map of a short but interesting near-by route which the motorist whom business bars from long tours may follow with advantage

MILEAGES

Total	**Intermediate**	
0.0	0.0	Columbus Circle, Broadway and Fifty-ninth street north on Broadway with trolley; under elevated at Lincoln Square.
0.7	0.7	Keep right of subway entrance and turn left on Seventy-second street.
1.0	0.3	End of street, turn right on Riverside Drive. Pass Schwab residence on right (1.1), Soldiers' and Sailors' Monument on left (1.8) and Bishop Potter's residence on right (corner Eighty-ninth street). Site of Strikers Bay Mansion between Ninety-sixth and Ninety-seventh streets, where Morris in 1837 was inspired to write "Woodman, Spare That Tree." The Carrigan House, with columns, corner 114th street, on site of original Nicholas de Peyster House. On the river bank opposite is the Columbia Boat House—over to the right are seen the buildings of Columbia College.
3.5	2.5	Curve right and left around Grant's Tomb, and cross long viaduct. Grant's Tomb, 1892-7—cost $600,000 by private subscription. Designed by J. H. Duncan; interior decorations by J. Massey Rhind. Trees beyond tomb planted by Li Hung Chang. See the grave of An Amiable Child (1792-97) nearby. The Claremont, now a fashionable restaurant, was built about 1790.
4.1	0.6	Turn right on 135th street one block.
4.2	0.1	Turn left into Broadway. Pass under footway connecting Trinity Cemeteries. Note the tablet on left commemorating the assault of Fort Washington. Within are tombs of J. J. Astor, Stephen Jumel, General Dix and others. In 1807 155th street was made the northern limit of the city. The Audubon Home (Minniesland) lies near the river in Audubon Park. On the left at 156th street is the new home of the American Geographical Society—opposite on 156th street is the Hispanic Museum and the Numismatic Museum.
5.3	1.1	Subway station, bear left into Lafayette Boulevard. Pass the Deaf and Dumb Asylum (on right, 5.9 m.). At 6.7 m. is the entrance (on left) of Fort Washington Park. An old redoubt (1776) lies beyond the deep railroad cut of 1847, the first railroad to enter the city. A hole in a flat rock marks the site of a telegraph mast used to carry wires across the river before the day of the submarine cable. Fort Washington Point (old Jeffreys Hook) is where Washington made crossings of the river, and where barges were sunk to keep back the British fleet (1776). Just beyond the park entrance, high up on a rock, is the castle-like residence of an Italian contractor. A flagpole marking the remains of Old Ft. Washington is visible to right, the highest point of land on Manhattan. At 7.5 a view to the left of Old Fort Tryon, and just beyond a wide sweep of the Hudson.
8.1	2.8	Five-corners, yellow church on left; turn left into Broadway. Cross long iron bridge over ship canal (9.2). At the five-corners is the site of the old Black Horse Tavern—pass on the left at the corner of Hawthorne street the Old Dyckman House of 1787, and ¼ m. beyond the 12 m. stone set into the wall of the Isham estate. The marble arch (8.9 m.) is the entrance to the Drake property. Beyond the ship canal to the left is Marble Hill, where earthworks were thrown up to protect Kings Bridge (1776).
9.5	1.4	Cross small iron bridge over Spuyten Duyvil Creek and immediately turn left, on 230th street. On the left (9.6 m.) is old Kings Bridge, first built 1693, destroyed in 1776 after Washington's retreat. Queens Bridge east of Broadway was built 1759 to avoid tolls on Kings Bridge and was broken down at the same time.

9.8 0.3 End of road, turn square left along creek. Go over railroad bridge (10.3 and 10.4). Caution for sharp right turn (10.5 m.). Note the old houses just before the railroad.

10.5 0.7 Fork, bear right up grade, curving right and left through crossroad.

10.8 0.3 Reverse fork, turn sharp right up grade on Parkway. At this point an unequaled view of the Hudson north and south.

11.0 0.2 Fork, bear right and next left on Spuyten Duyvil Parkway. Pass the Seton Hospital (on left 11.4 m.).

11.8 0.8 Fork, bear left, crossing Riverdale avenue (11.9 m.). Descend narrow winding road to the valley. On the right are the terminal yards of the subway.

12.7 0.9 End of road; turn left under elevated, and immediately right into Van Cortlandt Park. On the left is the old Van Cortlandt Mansion (1749) fronting the "Dutch Garden" with moat. Visit the museum in care of the Colonial Dames, guide book secured from custodian. Near the mansion is the "Rhinelander Sugar House Window" from the building at Rose and Duane streets, and the statue of Gen. Josiah Porter. To the north is the old parade or camping ground, now used for polo.

12.9 0.2 Left-hand road in front of underpass, turn square left.

13.0 0.1 Fork just beyond small wooden bridge, bear right. Pass the old Berrian graveyard (on right), the lake lying just beyond. Caution for sharp right turn under railroad (13.5). Vault Hill, with the old Van Cortlandt burial vault, lies to the left. Here were hidden the records of New York City in 1776.

13.8 0.8 Fork, bear left on parkway.

14.1 0.3 Fork, bear right up grade over winding road.

14.09 0.8 Turn left on Caryl avenue, immediately over railroad bridge.

15.1 0.2 End of street, turn right on Broadway.

15.4 0.3 Real estate office on left, turn left into Valentine Lane.

15.7 0.3 Meet trolley, turn left on Riverdale avenue. Straight ahead on Valentine Lane would take us past the lifeless trunk of an old chestnut, said to have been used by Washington for reconnoitering. At the corner of Hawthorne avenue is the old Lawrence House, once occupied by Washington's guide. On Riverdale avenue we pass the Clara Morris home (15.9), and just beyond the extensive Mt. St. Vincent Academy, in the grounds of which may be seen Font Hill, the former home of Actor Forrest.

16.7 1.0 Turn left on 253d street and descend winding grade.

17.2 0.5 End of road; turn left on Old Post Road. To the south on the Old Post Road are several houses of the eighteenth century, the Van Cortlandt Millers House and the Halley House, partly of stone, being the most interesting.

17.4 0.2 Turn left into Broadway.

17.5 0.1 Turn sharp right on Mosholu Parkway, passing under railroad (17.7).

17.8 0.3 Three-corners; turn right.

17.9 0.1 Fork; bear left. Cross railroad at grade (18.2).

18.4 0.5 Fork; golf links on right. Bear right along lake.

19.2 0.8 Turn sharp left around refreshment station up grade. Cross Jerome avenue (20.0). Bridge over Webster avenue (20.7) and railroad bridge (20.8), immediately curving right. In front is the museum at the entrance of Bronx Park, and we follow the park driveway for ¾ m.

20.9 1.7 Three-corners; curve left, then keep right.

21.3 0.4 Three-corners; curve left, avoiding right fork (21.5).

21.6 0.3 Turn right on Pelham avenue. Pass on the right the Stenton residence, with secret rooms, scene of the 1906 murder. In front stands the old willow; across the street is the Powell farmhouse, the oldest in Fordham. Passing under the Third avenue elevated, just beyond is Nolan's Hotel, where Washington once stopped.

5—Rounding a curve on Boulevard Lafayette

6—"The Concourse," New York's newest driveway

7—"Washington's Chestnut," on Valentine Avenue, Yonkers

8—Poe's cottage opposite Poe's Park on Kingsbridge r

22.4 0.8 Three-corners; bear right on Kingsbridge Road. On the right (22.5) is Poe's cottage, where he lived (1846-9), and wrote many poems, and where his wife, Virginia, died. A monument across the street in Poe's Park indicates the original location of the cottage.

22.7 0.3 Four-corners; turn sharp left into the "Concourse" wide boulevard.

25.8 3.1 Sigel Monument in fork; keep left on Concourse across 161st street (26.2 m.). Bear slightly right into Mott avenue.

26.4 0.6 Four-corners top of grade, subway station ahead on right; turn square across long iron bridge over Harlem River, curving slightly right beyond into 145th street.

27.0 0.6 Turn square left into Seventh avenue; straight ahead across St. Nicholas avenue and 116th street (28.5 m.).

28.7 1.7 Central Park at 110th street. Enter park, curving immediately right and shortly left. Caution for sharp right curve (29.0 m.).

29.3 0.6 Fork; just beyond stone bridge, bear right past Croton Reservoir (on left).

30.4 1.1 Fork; keep left on main driveway.

31.1 0.7 Webster Monument at fork of three roads; curve right.

31.6 0.5 Small statue in fork; bear right out of park into

31.7 0.1 Columbus Circle, 59th street and Central Park West.

The Enriching of Automobile Fuel

By JAMES S. MADISON

THE substances that have been most frequently used have been picric acid, containing 48 per cent. of oxygen, and ammonium nitrate, with 60 per cent. of oxygen. The use of these has not been attended with wholly satisfactory results, owing to their limited solubility in gasoline. The suggestion has been made that picric acid be dissolved in alcohol and then this solution added to the gasoline, but, unfortunately, gasoline and alcohol will not mix, the liquids separating into two layers, the gasoline being the upper one. There is another objection to the use of the two substances named above: they contain nitrogen, which, under the conditions existing in the cylinder at the instant of combustion, might form one of the oxides of nitrogen—substances that would tend to cause a rapid pitting and corrosion of the exhaust valves. Another method that has been employed to render the fuel more combustible depends for its effectiveness upon rendering the gasoline more volatile than it is under normal conditions. This is accomplished by adding to it some combustible substance of a considerably lower boiling point. The substances most commonly used are ligroin and petroleum ether. Sulphuric ether (ordinary ether) has also been used for the same purpose. The disadvantage of employing the latter is that it is only very slightly soluble in gasoline, and hence, if they be mixed, they soon separate into two layers.

The use of these and similar substances to increase the power has not been markedly successful. The result sought for may be easily attained by a slight modification of the method. Since the object desired is to introduce a larger proportion of oxygen into the mixture of gasoline vapor and air, this may be accomplished by using pure oxygen in its natural form—a gas—and introducing it directly into the cylinder along with the gasoline vapor.

So many improvements have been made in the manufacture of oxygen that it is now an article of commerce, and the compressed gas may be obtained in the market in steel cylinders of various sizes. A cylinder measuring 3 1-2 inches by 13 inches contains about 14 gallons of the gas.

The cylinder may be secured to the run-board, or other convenient place, and then connected with the air intake by means of ordinary rubber tubing. By opening the valve of the oxygen cylinder a fraction of a turn a small, steady stream of the oxygen gas will flow into the air-intake along with the air, thus increasing the proportion of oxygen in the mixture. This will cause the combustion in the cylinder of the engine to be more complete and more rapid, and the impulse delivered to the piston more powerful. The beginner should be content with mixing the oxygen with the air in very small quantities at first, or he may get explosions that are too powerful. He should not cut off the air supply entirely and attempt to substitute pure, undiluted oxygen.

This method will give better and more uniform results than the employment of such enrichers as mentioned above.

The cost of the oxygen is small. The cylinder is the only expensive part of the apparatus, but it is redeemed at its full value upon return to the dealer or factory.

Motor Notes from North Star State

MINNEAPOLIS, July 18—The annual tour of the Minnesota State A. A. will start from St. Paul Friday, and it is estimated that 60 or more cars will take part in the run to Sioux Falls, S. D., and return. The tour will finish at Minneapolis.

The Northland Motor Car Company has been reorganized. Details were completed last week, when George G. Ackley, a banker at Ramona, S. D., purchased an interest in the concern and will actively engage in the business. Mr. Ackley has been chosen vice-president of the company and will assume the general management during the coming week. Asa Paine still retains his interest as a co-partner, as does W. D. Rightmire, who will continue in the capacity of sales manager.

H. A. Peterson, of the Barclay Auto Company, spent the week in Detroit making arrangements for Chalmers and Hudson demonstrators for 1911. It is expected that the first of the new models of the former make will reach the Minneapolis distributors about the last of this week. The Hudson cars are expected a few days later.

John H. Shields, who is now in Los Angeles in the interests of the H. E. Wilcox Motor Car Company, will hereafter have a broader field to work, for his duties as sales manager will take him to practically every large city in the country. An active campaign for truck business has been inaugurated in California, and the concern at present has demonstrators at work in that state.

The Regal Motor Company, of Detroit, Mich., will soon establish a branch in Minneapolis. Articles of incorporation have been filed by the Minneapolis Regal Auto Company, with a capital of $25,000, the incorporators being C. W. Reynolds, H. S. Haynes, J. P. McGuire, E. C. Noyes, T. L. Myhra and C. H. Dickson.

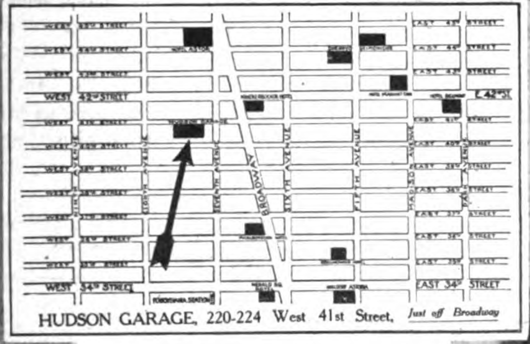
Messrs. Haynes, W. H. Grower and J. P. McGuire have also filed papers for another corporation, to be known as the Motor Equipment Company, with $50,000 capital.

Inter-State Used Reverse Gear to Win

At the hill climb, conducted July 10 on Mount Morris hill, near Denver, Col., the chief prize was won by an Inter-State "40," driven by F. A. King and R. Berry. The course is 1¼ miles long, and the ascent is slightly over 1,000 feet. The maximum grade is 35 per cent., and the course tortuous in the extreme. The winner covered this course in 5:35 3-5. Most of the way the Inter-State used its intermediate gear, but there was one place where it was necessary to use the reverse gear to back up one of the stiff-graded curves.

Among Modern Garages---The Hudson

Door to the Repair Shop



HUDSON GARAGE, 220-224 West 41st Street, *Just off Broadway*

Wash Stand

RECOGNIZING the sweeping character of the demand for specific reforms in garage work, the better class of establishments of this character in New York City are organizing and equipping to meet the class of competition which has merit for its basis. The illustrations as here presented are of the Hudson Garage, located at 220-244 West Forty-first street, New York City. This establishment strikes one as having a peculiar merit in that there is a large, well-lighted floor area for the proper storage of cars, plenty of maneuvering room, so that they may be driven in or out without loss of time, or without endangering the mud-guards, and the arrangements provided for maintaining the automobiles in good working order have the virtue of being adequate for the purpose, and ingeniously installed.

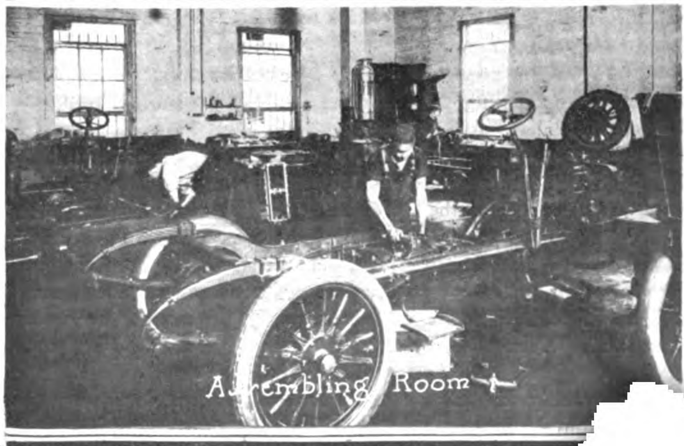
One idea that could be very well copied by up-to-date garage owners is shown in the form of a diagram of the streets of New York. It indicates the locations of the principal hostelries and how to get from them to the Hudson Garage. There is another point that strikes a keen observer, which takes the form of a locked and barred entrance to the assembling room. One of the most annoying situations from an autoist's point of view is represented by having his car disassembled in a room which is accessible to every one who happens to come around for any purpose whatsoever. In the Hudson Garage the assembling room is a well-lighted and substantially equipped place, where cars are disassembled for purposes of repair, and after the repair parts are completed in the machine shop they are transferred to the repair shop, and are kept in an orderly array, with no chance of being lost, strayed or stolen, for the very good reason that the room is not accessible to outsiders, and the artisans who have access thereto are enabled to do so by properly approaching a locked and barred door.

A corner of the machine shop is shown. It is not large, but the equipment is designed to facilitate work.

In conclusion, the most striking feature of this garage will be given the barest mention. The repair shop, in proportion to the storage room and the number of cars handled, is actually diminutive, and yet it is large enough to do all the work that has to be done in the maintenance of the cars therein kept. There are probably two reasons for this, one of which is due to the fact that the better class of cars are handled, and the other reason is that the monthly rate for storage is regarded by the management as sufficient for its ends, and it prefers to acquire a reputation which will support it in the garage business rather than to operate a large repair shop as an annex, and by neglecting the cars, and in other ways, make work for the repair shop. This example is an excellent illustration of the fact that a large monthly repair bill is not a necessary adjunct to an automobile kept in a public garage.

Paint Shop

Machine Shop



Assembling Room

In the Realm of the Makers

The Keystone Sheet Metal Company, of Ambridge, Pa., will start at once to manufacture mud guards and shields for automobiles at its plant down the Ohio River.

The Badger Tire Repair Company, of Milwaukee, Wis., has been incorporated with a capital stock of $5,000 by B. A. Massee, W. L. Baumbach and William A. McMillan.

The F. A. L. Motor Car Company, of Chicago, which sought a location at Kenosha, Wis., is now negotiating with the commercial organizations at Waukegan, Ill., for a site.

The Banker Wind Shield Company has just placed on the market its 1911 Model Wind Shield. The new model has an improved automatic ball ratchet hinge which allows the upper half of the shield to be placed at any desired angle.

The Holbrook-Armstrong Iron Company, of Racine, Wis., is completing the work of installing $40,000 worth of new machinery for the production of motors and car parts which will be used by the Racine-Sattley Company of Racine.

The McGraw Tire and Rubber Company has broken ground for a large addition to its present plant in East Palestine, O. It will add many new tire-building machines so that the output will be doubled, and it will employ 200 men.

Hopewell Brothers, makers of auto fabric specialties, Boston, have entered suit in the Federal Circuit Court against two alleged infringers of their patent on a certain type of tire case. Notice of the suit has been given to the members of the trade.

Three big companies allied with the automobile manufacturing industry have been secured for Pontiac. They are the Michigan Stamping Company, capital, $150,000; the Vulcan Gear Works, capital, $100,000, and the Pontiac Foundry Company, capital $80,000.

The C. A. Shaler Company, of Waupun, Wis., manufacturer of the Shaler vulcanizer, has awarded contracts for the construction of a new factory. The main building will be of reinforced concrete construction, 30 by 130 feet in ground dimensions, 90 feet to be two stories and the remainder one story high. The present plant will be used as a warehouse and storage.

The Badger Four-Wheel Drive Motor Company, of Clintonville, Wis., has procured subscriptions for $30,000 worth of stock, and it is now being permanently organized. Most of the stock was taken by business men at Clintonville. Both pleasure cars and commercial cars will be built, and it is intended to market the car for the 1911 season.

The Gaeth Automobile Company, capital $500,000, has been formed at Pittsburg by George S. Patterson, W. J. Harvey and George Protzman, of that city. It is backed by Cleveland capital and has secured a site in the Turtle Creek Valley, where a plant will be erected.

Omaha auto dealers are the principal promoters of the aviation meet to be held in Omaha July 23. The Midwest Aviation Meet Company has been incorporated with these officers: President, J. J. Deright; vice-president, R. R. Kimball; secretary and manager, Clarke Powell; treasurer, Gould Dietz.

The Ball Multi-Spark Plug Company has opened a factory at 917 Hennepin avenue, Minneapolis, for the manufacture of a newly patented spark plug. The company, which comes from Aberdeen, S. D., is headed by A. H. Pease and W. M. Pease, and has a capitalization of $100,000, of which $50,000 is paid up.

Several finished taxicab bodies and tops owned by the E. R. Thomas Motor Company were destroyed by a fire in the shipping room of the Buffalo plant recently. The flames caused a loss of about $10,000. The shipping room is situated a considerable distance from the main plant of the Thomas company, which was in no danger at any time.

The Omaha Motor Club, which was organized to promote a new mile auto racing track for Omaha, has incorporated with a capital stock of $10,000. The officers are: Ole Hibner, president; C. L. Gould, first vice-president; W. J. Kirkland, secretary; Eugene Silver, treasurer; directors, W. D. Hosford, W. L. Huffman, George F. Rheim, L. E. Doty and Otto P. Nestman.

Martin L. Pulcher has resigned his position as secretary and treasurer for the Oakland Motor Car Company at Pontiac, Mich. The resignation was to take effect July 1, but he will remain with the company until his successor is appointed from the general office of the General Motors Company in New York. He announces that he is leaving the Oakland company to turn his attention to the manufacture of commercial trucks.

Jesse Froelich, of the Benz Auto Import Company, has sailed for a business trip through Europe. At Mannheim, Germany, he will meet Prince Henry. Mr. Froelich will consult Fritz Erle, one of the Benz staff of mechanical engineers, who drove in the Savannah Grand Prize race, in reference to the Benz entries in the American contests next Fall, including the Vanderbilt Cup race, the Grand Prize race on the Motor Parkway, and the Fairmount Park race.

R. E. Glass, who early this year was made a director of the Michelin Tire Company, Milltown, N. J., has just been elected treasurer, succeeding E. Fontaine, who resigned recently.

The Millersburg (Ohio) Automobile Club has been formed, with W. W. Adams, president; B. S. Bontrager, secretary, and W. N. Crowe, W. S. Hanna and C. R. Carey as directors.

Contract to build the new home of the Automobile Club of Buffalo at Clarence Hollow, near that city, has been given to Metz Bros., Buffalo. It is expected that the clubhouse will be finished this Summer. It is to cost $50,000.

The Pittsburgh Automobile Dealers' Association is holding very successful monthly meetings the first Thursday of each month at its headquarters on Baum street, East End. The association held its regular annual outing Saturday, June 25.

The Superior Rubber and Manufacturing Company, of Akron, was incorporated with a capital stock of $10,000 to manufacture automobile tires. The incorporators were J. M. Hyatt, R. E. Nicol, W. J. Holtenstine, A. B. McAllister, and others.

The New Castle Automobile Club is offering prizes ranging from $50 to $5 for the percentage of improvements made this summer in the roads of each township in Lawrence County, 30 miles north of Pittsburg. Prizes will also be offered to farmers for the use of road drags.

Automobilists of Allegheny County are complaining severely about the careless manner in which the roads of this county are being oiled. They say that the Road Commissioner is not only allowing much oil to be wasted, but that by the present system of sprinkling the roads become like skating rinks, so that automobiles are constantly skidding.

That the R. M. Owen Company, of New York, which has the contract for the sale of the Reo pleasure cars, also will have charge of the selling end of the new truck business which the Reo company is about to enter, is the announcement made at the office of the Reo company following a visit from R. M. Owen. It is probable that the manufacture of trucks will be begun about September 1.

Directors of the Portland Automobile Club have decided to co-operate with the newly organized Vancouver, Wash., Automobile Club for the improvement of the highway between Vancouver and Kelso. Automobile owners are directly interested in the improvement of this road for the reason that it leads to Seattle and the Puget Sound country. The Vancouver club has only been organized a few weeks, with Thomas P. Clark, president; Will B. Dubois, secretary; C. N. Quanberg, vice-president; and Charles B. Sears, treasurer.

At Norwalk, La., on July 4, the Westcott "40," owned by Dyson & Son, won two firsts in the hill climb from a standing start.

T. E. Adams has been elected president and treasurer of the Hol-Tan Company, handling the Lancia. The offices of the company are at 1741 Broadway, New York.

Jack L. Straub, secretary and treasurer of the J. S. Bretz Company, sailed for a five-weeks business trip to Europe, on the American-line steamer St. Louis.

At Dallas, Texas, on the Fourth of July, the Kissel "30" won the three-mile stock car event. The Kissel L. D. "10" baby tonneau finished ahead of five standard makes in this event.

Wallace and De Wild, of Newark, N. J., have taken the agency of the Cole "30" for Newark and Essex County for 1911, and will soon open a garage and salesroom in vicinity of Halsey street.

Louis C. Marburg, secretary and treasurer of Marburg Bros., Inc., sailed on the Celtic to attend a meeting of the Society of Mechanical Engineers at Birmingham. He is going from there to the Continent.

The Champion Company, formerly of 36 Whittier street, Boston, Mass., manufacturers of Champion spark plugs, have recently moved to Toledo, O. For the Eastern trade it will still maintain an office at 394 Atlantic avenue, Boston, Mass.

Weldon A. Fosdick, formerly salesmanager of the Moline Automobile Company of Texas, has associated himself with the Roberts Motor Car Company, at Dallas, Tex., as its salesmanager and secretary. This company is the State agent for the Thomas flyers.

At a recent test conducted at Columbia University, the half-inch size "Motorope" handled by B. M. Asch, 1777 Broadway, showed a breaking strength of 2910 pounds. The three-quarter inch size broke at 5019 pounds. It is made for an emergency aid for automobilists. It is light and of small bulk.

L. B. Williams, veteran English motorist, who drove in the preliminary trials of the Vanderbilt Cup Race in 1906 and who was also a contender in the Gordon Bennett road race in Ireland and the Grand Prix at Ardennes, France, has joined the selling force of the Westcott Motor Car Company, of Richmond, Ind., and will be located in New York city with the Dunlop-Taylor Motor Co., of 1876 Broadway.

The Saxon Lamp Company of New York City, manufacturers of headlights, tail lamps, generators, electric lamps, etc., has increased its capital stock to an authorized capital of $50,000 and elected the following officers: H. Saxon, Pres.; Smalley Daniels, Vice-Pres.; J. S. Taylor, Sec., and J. C. Nichols, Treas. The above constituting the Board of Directors. The company may move to Michigan or Indiana.

Agency and Garage News

The Maytag automobile is now established in Spokane, and is in the hands of Ed. A. Leach and W. G. Carr.

The Brush Auto Company has opened a Portland agency at 608-610 Washington street. William Wilzinski is in charge.

The Goodrich Rubber Company has opened a branch in Spokane at 151 Post street under the management of W. J. Rooper.

Jones & Gardner, of Union City, Pa., are building a fine garage 38 by 75 feet, and will start an automobile repair shop at once.

Eddie Bald, Pittsburgh agent for the Everett car, was referee in the Fourth of July hill climbing contest at New Castle, Pa.

C. W. Cain has taken the agency for the Croxton-Keeton cars in Ohio, Indiana, Kentucky and West Virginia. He is now busy establishing local agencies.

The Palmer-Singer Distributing Company, handling the Palmer-Singer cars, have opened a new garage at Ninth street and Tacoma avenue, Tacoma, and are exhibiting a number of the 1911 models.

The Pittsburgh Automobile Company has secured the exclusive agency for Oakland automobiles for Pittsburgh and towns within a radius of 200 miles. The sales will be managed by Julian Howe, and the line will consist of touring cars, roadsters and runabouts.

G. C. Murray, representing the Northwest Buick Company in Spokane, recently established an agency in Sandpoint, Idaho. On account of the number of new cars recently purchased in that territory the roads are being improved in the vicinity of Lake Pend Oreille.

William A. Ryan, who for the past three years has represented the E. R. Thomas Motor Company as district sales manager in the middle West, with headquarters at Chicago, has resigned, and will enter the retail field at Des Moines, Iowa, beginning with the 1911 season, on July 1. He has incorporated a company to be known as the Ryan Motors Company, and has contracted for a large lot of Chalmers cars.

The Buick Motor Company this week moved into its new rooms at 509-513 Erie street, where it now has one of the best garages and repair departments in Toledo. Three floors and basement are used by the concern, a huge elevator serving to hoist cars to any part of the building. The first floor is devoted to the storing of cars, the second floor to the repair work. A complete parts department will be maintained, where every piece entering a Buick or Reliance truck can be secured.

Peter S. Steenstrup and wife recently made the trip by auto from Portland to Medford, Ore. Mr. Steenstrup reports a most enjoyable outing.

Harry Fosdick has resigned as vice-president and general manager of the Hol-Tan Company, of New York, American agent for the Lancia car.

H. N. Sankey, one of the best known automobilists in Pennsylvania, has been elected treasurer and general manager of the Kittanning Automobile Company at Kittanning, Pa.

Charles E. J. Lang, secretary-treasurer of the Rauch & Lang Carriage Company, of Pittsburgh, is starting for an extended tour around the world. He will visit all the big vehicle-manufacturing plants across the water.

H. F. Fulton, who has been with the Citizens' Motor Car Company, Cincinnati, for a number of years, has severed his connection with that company and will be in the future identified with the Charles Hanauer Auto Company, having in his charge the line of Pierce cars.

The Hoffman Automobile Company has opened a garage at Bedford, Pa. This company has been in business six years, with main offices at Meyersdale, Pa. The Bedford plant will be in charge of C. J. Rowe, of Meyersdale, and H. W. Cunard, of Everett, Pa., and will handle the Maxwell, Columbia and Stoddard-Dayton cars.

Work on the new building which the B. F. Goodrich Tire Company is having erected in Race street, south of Twelfth, Cincinnati, is progressing. It will be two stories in height, of brick, and will cost about $20,000. The interior is to be handsomely finished. J. B. Blake, new manager of the company's branch here, arrived from Detroit recently.

The Pittsburgh-Chalmers Company has been organized, with Ralph G. Kennedy as manager, to handle the Chalmers line in that city. It will be located on Negley avenue near Centre. Mr. Kennedy has been in the automobile business in Pittsburgh 15 years, and was for a long time manager of the local branch of the Morgan-Wright Lumber Company.

The contract between the Cadillac company and Alvan T. Fuller as its Boston agent expired a few days ago and Alfred Measure who recently formed the Cadillac Automobile Company of Boston to handle this car took full charge of the agency. He has a salesroom on Boylston street, and Louis J. Sackett, who had charge of the Cadillac department for Mr. Fuller, has joined the new concern. A section of the Motor Mart has been secured for a repair department.

Accessories Occupy a Prominent Place

AN AUTOMATIC OIL CLEANSER AND COOLER

The importance of proper lubrication to the life of the motor and to the continued rotundity of the pocketbook is, or should be, appreciated by every motorist. Even the best of oils, after being in use in a crankcase for some time, becomes hot, dirty and gritty; dust is taken in through the "breathers," remnants of core sand from the castings, and carbon, which leaks past the cylinders, collect in relatively large quantities until the oil becomes, in a measure, a grinding compound that cannot fail to act deleteriously on the surfaces it is designed to lubricate. Hot oil, in addition to the readiness with which it leaks through bearings, does not possess the lubricating qualities of cool, heavy oil, which increases the compression, and, therefore, the power.

A system of automatically filtering and cooling the lubricating oil of automobile engines has been designed and patented by H. F. Maranville, a pioneer in this line of work. It is absolutely meddler-proof, and requires no more attention than the radiator or the gasoline tank. The hot, thin and dirty oil is pumped automatically to a filter placed sufficiently high to secure gravity feed on the return. The oil flows through, first, a cylindrical strainer fitted with a removable sediment pan, then through a cylinder filled with bone black, after which it passes through a single ply of specially woven filtering cloth, and then to the bottom of the filter, rising again through a water compartment, where it is washed and cooled, passing through the water separator into the pure oil reservoir, flowing thence by gravity to the crankcase—repeating this operation continuously as long as the motor is running. A clean-out plug is placed at the bottom of the filter to facilitate the removal of accumulations, while on the opposite side there is a filler where the supply of water may be replenished when necessary.

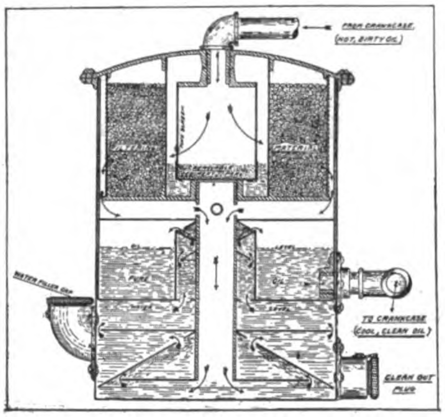
The principle can be applied to almost any present-day motor by making slight changes in the design and pattern of the crankcase.

The same device, with a few minor changes necessitated by the use of the flush system of lubrication, has been in successful use for many months in the rail and billet rolling mills of the Indiana Steel Company's works at Gary, Ind. The filter equipment here is, however, on an immense scale, being designed to cleanse 20,000 gallons of lubricating oil every 24 hours.

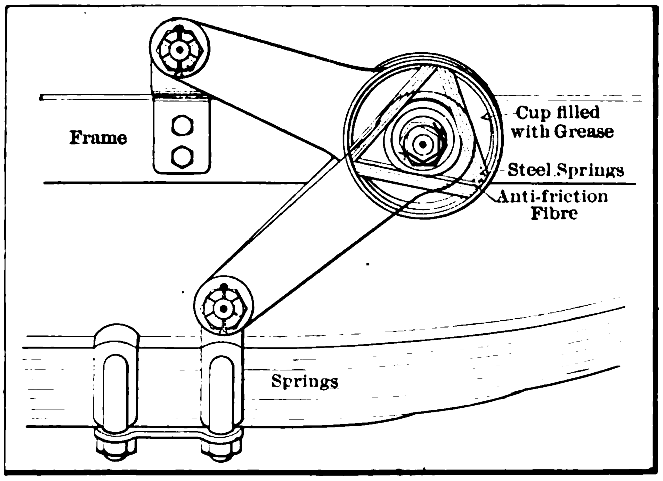
AN EFFECTIVE SHOCK ABSORBER

In the accompanying illustration is shown the Connecticut Shock Absorber, manufactured by the company of the same name at its factory in Meriden, Conn. The working parts of this device consist of a three-face cam working between three sets of springs of suitable tension to give the necessary resistance for the different weights of cars. These springs are located in a triangular position inside the retaining shell or cup with a piece of special bone fiber inserted between the face of the cam and the spring, so as to eliminate any possible wear. The case is packed with non-fluid oil, which surrounds the cam and springs, keeping them well lubricated at all times. The case is made grease-tight, and it is therefore impossible for the grease to leak out, or for water or dirt to get in.

The triangular arrangement of the springs and cam insures the placing of the strain on the cams, the bearings for the cam hubs in the shell of the shock absorber receiving practically no wear at all.



The H-F-M automatic oil filter and cooler



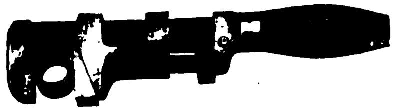
The Connecticut Shock Absorber in position

To insure proper adjustment of these absorbers they are provided with a serrated disk in order to secure the proper distance between the arms to obtain the neutral position.

During normal movement the absorber does not exert a braking effect, the springs not being brought into action until there is an excessive up-and-down movement of the car body, when the cam rides on the springs, exerting a braking effect and holding the body where it belongs. An added advantage is that in passing over smooth roads the device allows the full flexibility of the springs.

A HIGH-CLASS, POWERFUL TOOL

The pipe wrench here shown is made by the Brosnihan Wrench Company, 31 Hermon street, Worcester, Mass. The movable wedge or sleeve jaw is held against a pipe by a spring, and, grasping it instantly on the downward movement of the handle, does away with all lost motion. The jaws are made of hardened tool steel, tempered in oil.

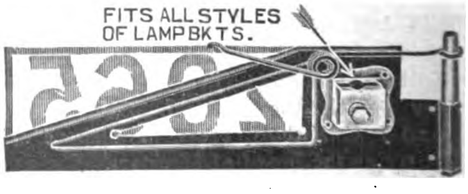


The Brosnihan pipe wrench

BALZER LICENSE PLATE HOLDER

This device is of very great convenience when passing from one State to another, for the plate can be removed and another put in its place by simply lifting a spring. It also holds the plate so it will not swing, which is an important feature, as many States now enforce this regulation.

This holder is so arranged that the rays of the white light from the rear lamp fall on the number plate. It is attached by removing the rear lamp and placing the socket of the license holder on the lamp bracket, already on the car; the lamp is then placed on a bracket provided on one end of the license plate holder. The other end of the spring which holds the plate down keeps the lamp on the bracket. The Gus Balzer Company, Inc., is located at 1777 Broadway, New York.

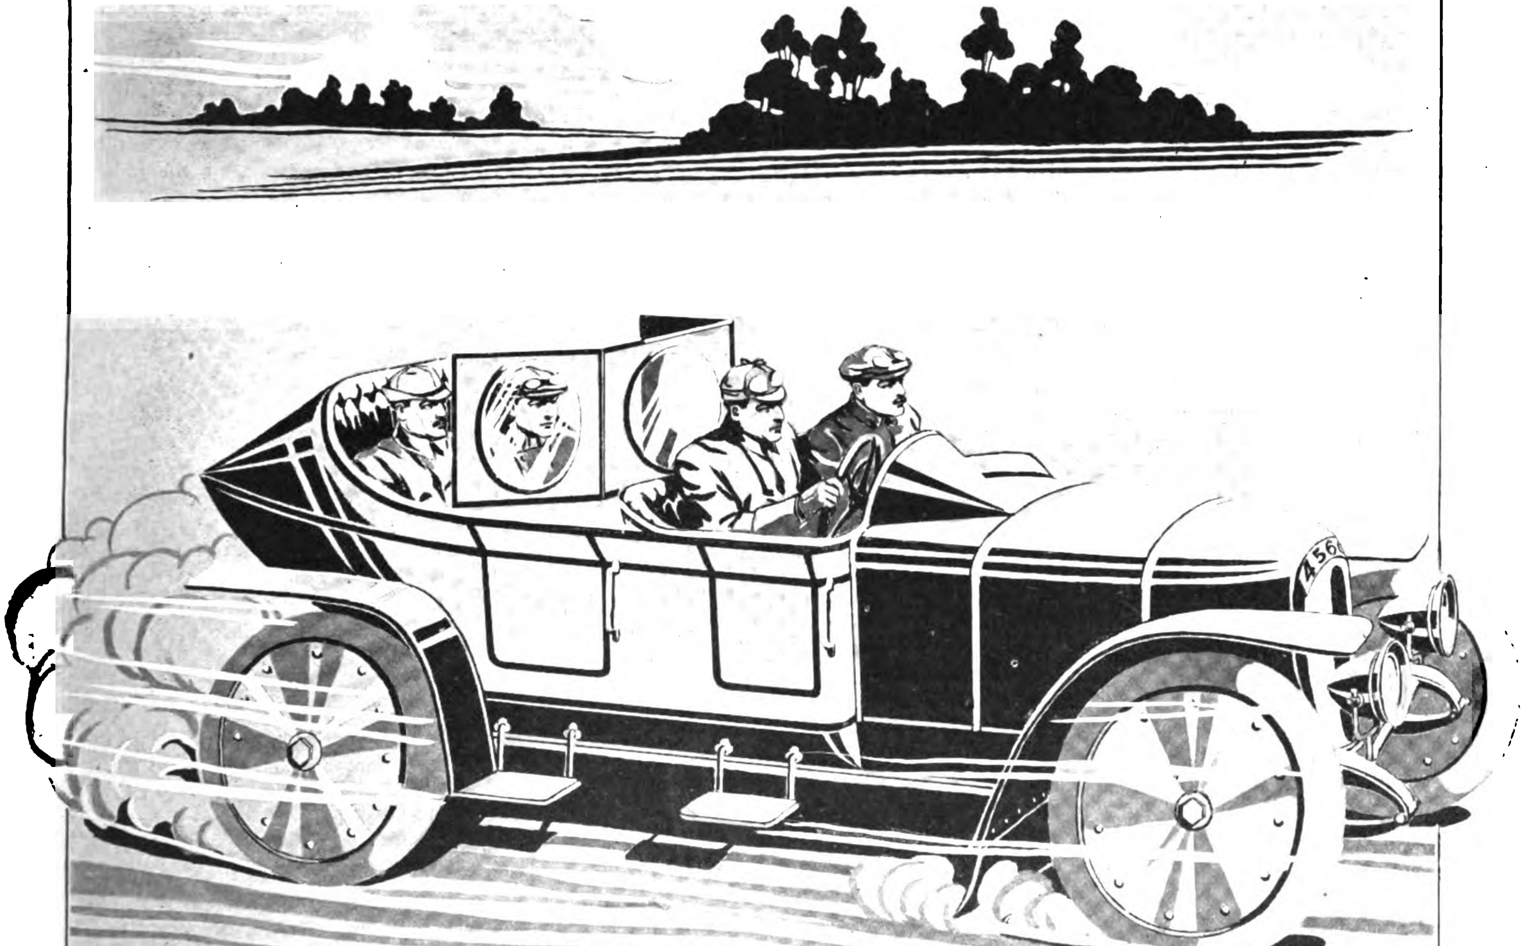


Rear view of Balzer license plate holder

Vol. XXIII NEW YORK—THURSDAY, JULY 28, 1910—CHICAGO No. 4

THE AUTOMOBILE

STANDARDIZATION IS THE NEED OF THE HOUR



STANDARDIZATION is the goal to which the automobile is traveling. The journey is a long one. Headway is beset by impediments at every hand, and, unfortunately, this giant benefactor of every art, with the silence of winged time, passes up and down the highway of progress, bowing to all who have lifted the veil of ignorance, unseen, however, by the scattered mob.

If it is admitted that a steering wheel should be fitted with a gear that will require a certain angular displacement in order to cant the front road wheels from the straight-ahead position to the angle of locking, and granting that this condition is not adhered to in every automobile made, viewing the whole situation in perspective, does it not represent incoherence of design?

Memory permitting, ancestry is lauded; the fair pages of history are scanned for a glimpse of a situation which reflects honor upon the individual and nations of individuals. As in a looking-glass, man contemplates the past, hoping, perchance, that grandfather carried a gun or spiked a cannon in a bygone fray. Discovering that glory of history casts its beam upon the family tree, the members thereof shoulder the burden of standardization as it is thus emanated.

Darwin traced the ancestry of man back to the time when he hung by his tail to the limb of a tree. This brave ancestor pushed ahead to go ahead, pushed to the right to go right, pushed to the left to go left, pushed to the rear to go back, and held back to stop. If the fair pages of history are to serve as the mirror to guide the faltering steps, is there any justification for gazing at that part of the mirror which discloses the "spiker of a gun" to the exclusion of the other precedents?

Habit is strong; it is the product of two schools. Nature is the "Master" of one, and man acquires the other by directly imbibing. If a yellow streak can be transmitted for seven generations, allowing that Nature does not discriminate, is it not also true that man naturally performs certain acts in the certain ways that were handed down from the dusty pages of the past? If so, is it not right to suppose that the driver of an automobile will subconsciously pull upon the emergency brakes to stop a car?

Piano-forte keyboards are universal. A musician from Hungary who sojourns in Bombay approaches the piano there, knowing full well that it is similar to the one in his own drawing room at home. Why should it be any different? Does it not represent the embodiment of all experience? An autoist, after using his automobile until it is no longer fit for service, goes to the maker for a new one; why should he have to unlearn all that he has acquired? Is there any excuse for asking him to learn to play on a newly arranged set of keys?

Automobile makers, doing big business, have well-appointed business offices. What have they there? Stenographers! Why? Is it not because they are deft, efficient, accurate, and reliable? When one retires, and a new one is engaged, does the manager think to inquire whether or not the new aspirant knows the keyboard of the type of machine that is used in that particular office? Is this silence due to the fact that the manager thinks that the new stenographer is so experienced as to know everything? No. The great "head" is alive to the fact that the keyboard is standard; he would not have purchased a machine excepting with a standard keyboard.

Ships that sail the "high seas," that make the "Grand Round" in a year and a day, that take departure with a full crew, that could not possibly survive a single storm of magnitude without men who know every rope in the whole make-up, rarely complete the homeward voyage with the men in the folks-hold who ship for the voyage. Why is it that a ship can sail from Liverpool, journey to Calcutta, lose a man overboard, replace him at the port of entry, and never give a thought as to the capability of the seaman?

Similarity of arrangement and fixed locations of the belaying pins to which the seamen make fast the clewlines, leechlines, bunt lines, fore braces, main braces, mizzen braces, staysail halliards, jib halliards, and the numerous other gear which puzzle the land-lubber, are at the bottom of it all. When the "braces" are made shipshape, the ensign is dipped in salute as the good ship noses the narrows passing the "fort," as the yards are squared to the passing breeze, as the inhabitants of the lowland hear but faintly the mellowed sound as the officer of the watch in bold confidence gives commands in quick succession: "Haul around the crossjack yard! Hard down the wheel!" As the gamut is run, as the ship responds to the trim of the sails, as the seamen bend with alacrity, is there any sign of confusion, any indication of uncertainty? No. Why? Standardization!

Come, let us join the fashionable audience at the Metropolitan Opera. It is a gala night. Gathered from the capitals of nations, there to entrance with art, are the prime donne and a galaxy. The text of the opera is but a detail, and the plot is scarcely noticed. It is the silver tongue, the song of the oriole, and the blandishment of the thrush that casts a spell o'er the audience. The mingling of the thousand-voiced chorus brings bliss to the refined ear, and when the situation is properly explained, it will be numbered among the normal expectations, the fact that little effort was demanded of the great impresario to weld this aggregation from separate units, gathered from many lands, into a homogeneous unit. What is the secret? Standardization—all the voices are pitched to the "International" key.

Railroads Were Standardized After a Long Struggle

It is well within the memory of the present generation when railroads were on the same more or less heterogeneous basis as now confronts the users of automobiles. The gauge of trackage varied from 21 1-2 inches to 3 feet 3 3-8 inches, and upwards to 4 feet 8 1-2 inches, stopping at 60 inches, excepting in one or two isolated cases. It requires no stretch of the imagination to arrive at the conclusion that a freight car built to travel on a 4-foot 8 1-2-inch gauge track would have to stop going at the end of its own line. A connecting line with a meter gauge (3 feet 3 3-8 inches) could only co-operate with the line of differing gauge to the extent that the freight cars would have to be unloaded from the meter-gauge line, and the freight would have to be transferred to the cars standing upon the other line. This handling and rehandling of freight resulted in a loss to the roads, and ultimately a loss to the public at large, it being the case that quasi-public institutions must thrive and prosper, or the public must share in the loss.

In the course of time it dawned upon the heads of railroads that it was cheaper to transport goods through to destination without rehandling, than it was to be the sole owner of a short line and incur the cost of rehandling freight. The early history of railroading was that of the "big frog in the little pond." The history, in fine, of the character of men who headed these disjointed railroads was that of efforts which ultimately led to the writing of an epitaph, always of the men, but, unfortunately, frequently of the efforts they misdirected.

The time arrived in the history of railroads when the car builders assembled in conclave and contrived what is known as the M. C. B. (Master Car Builders' Specifications). As the result of the labors of the great minds which undertook this work every dimension of each part which enters into railroading in any way is standardized, and a wheel or an axle or what not may be had from any shop in the land and it will fit into place in any car made.

Standardization Is the Next Mile-Stone Ahead

Every industry traverses the road called progress; it has its inception in the fertile brain of the inventor whose ability to think twice in the same direction is always in question. The breath of commercialism instills life in the invention, emanating from the infected thorax of the "promoter," who, as a matter of course, "tries it on the dog."

With a sufficient amount of merit residing in the main idea, despite the imperfections of the promoter's method, invention survives, and art grows. The next step in the life of an invention takes its departure at the instant of capitalizing merit with the expectation of trading off a dollar's worth of value per dollar expended, figuring in a return on the property for the investor. It makes no difference whether the investor is he who furnishes the capital for the building of the device, or whether he is in the guise of a purchaser who expects to use the same and profit thereby.

Since it is true that the standardizing process has proven of unquestionable benefit in the arts thus far enumerated, it only remains to call attention to some of the advantages, applying them to the automobile, discussing them from the two points of view. Activity may now be noticed among makers and work which is being done by the Society of Automobile Engineers, with a

PEDALS A[illegible] STRIKING DISTANCE OF A STANDARDIZED CONDITION view to the standardization of the materials for use in the manufacture of cars.

Properly Classified Materials Represent First Requisite

Users of automobiles, with a limited vision, based wholly upon their own needs and influenced by the shortcomings of the cars they employ, reach the hasty conclusion that the question of standardization is no greater than the one they see. It is a gross injustice to the great problem involved to assume for a moment that a standardization product can be evolved from a mere aggregation of a kindred form of materials. It is first necessary to classify and standardize the materials which are to be used, and only then will it be feasible to place the stamp of standardization upon the finished product.

It may be taken for granted that the companies, severally and collectively, will find ways and means to cope with the standardization problem as it refers to the materials used, but it remains to be seen how the plans will be so unified that drivers of automobiles will not have to unlearn what they acquire with one car when they take up another and different make.

Habit Becomes an Asset to a Driver of a Car

When an aspiring autoist purchases his first car he assumes the position and prerogative of a juvenile in the primary grade at school, and he learns the A B C of the automobile. If it is a good school (automobile) the basis of his future education will be well founded, and as he progresses from grade to grade he will acquire habits which to him will be an asset for all the time to come, and he will thereafter subconsciously direct his efforts in precisely the right channel in every emergency, so that accidents, as the result of false moves, will scarcely be chargeable to him.

When the autoist graduates from this school (automobile) and he elects to transfer his affection to another, if there is no standard plan between them, the poor autoist will be in a most unfortunate position. Force of the habit, acquired under the conditions of his previous training, will be as a handicap to him in his every move. He will be in the position of the piano-forte artist who is suddenly confronted with a keyboard that is not built in accordance with the customary standard, and instead of moving under the force of acquired habit, effort will be conscious, more or less studied, but always retarded by subconscious influence as dictated by the habits previously acquired.

It is not the intention here, at this time, to offer any suggestion leading up to the struggle for unification of the control systems of automobiles. Perhaps the state of the art is not as yet such that the various makers of automobiles would be content to send delegates to a convention empowering them to agree upon a standard set of control units, such as might be written in indelible ink and hung up in front of every draftsman in every shop, telling him in precise language how every part should be made and the relations of parts, so that an autoist would be able to get into any car and drive away with the assurance to himself that the habits previously acquired in the process of driving other cars would stand him in good stead in the face of a new emergency.

It is not believed that all the accidents that we hear of from time to time are due to mistakes made by drivers, but it must be appreciated that well-drilled men are more capable of conducting themselves on a basis of precision of movement than is possible otherwise; but this thought leads up to the really serious situation, and it is worth repeating here: Drill a man to proficiency in one way and suddenly require him to act against the habit acquired and he will go wrong.

Present Situation as It Confronts the Autoist

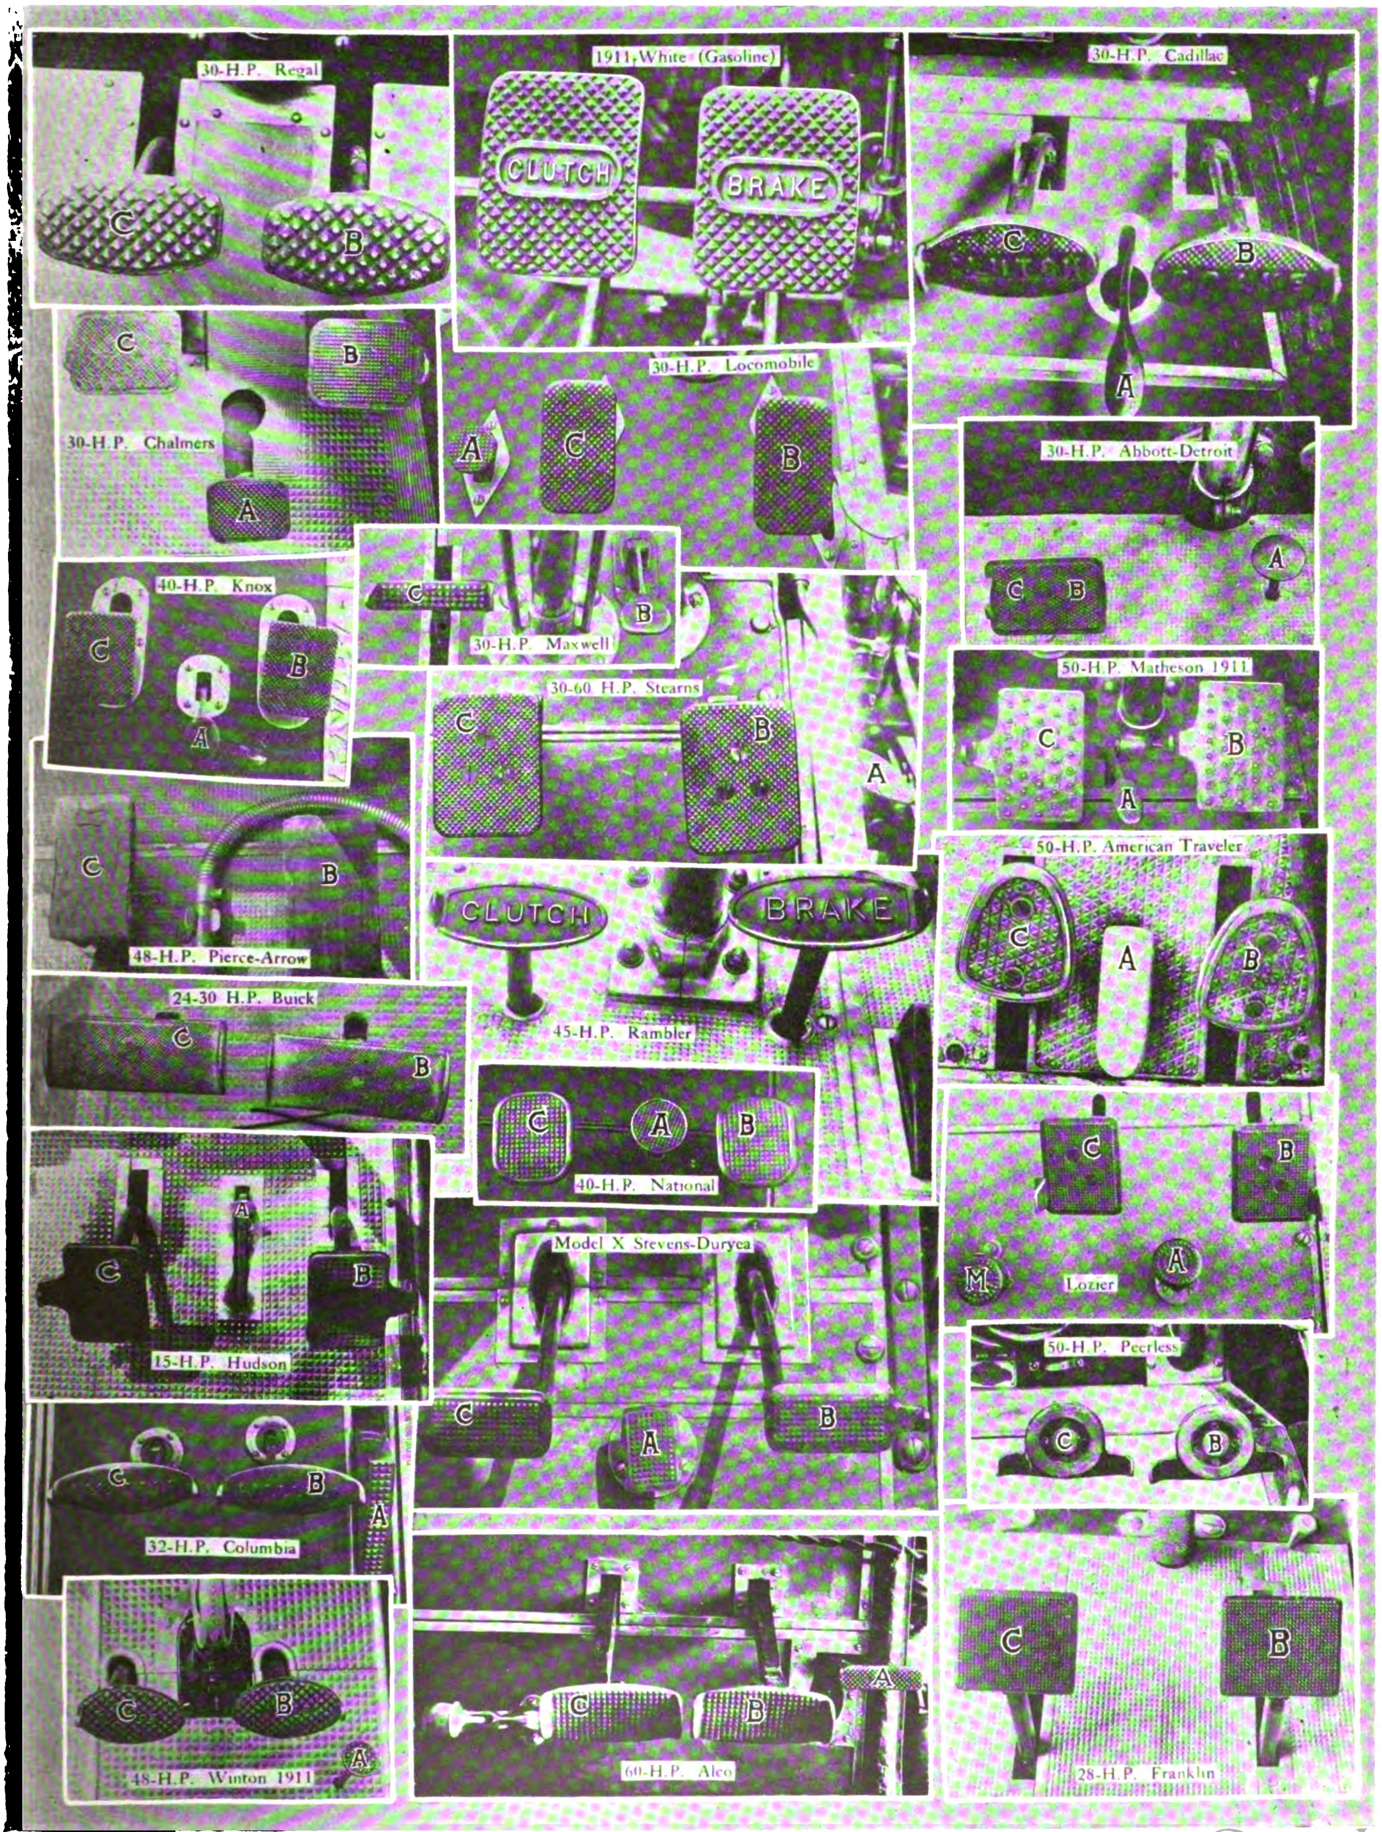
For the purpose of showing that there is no approach to standardization in the cars as they are now made, the staff photographer of The Automobile called at the sales agencies of makers indiscriminately, and with few exceptions succeeded in taking photographs of the latest and most up-to-date cars from three points of view: (a) Showing the side levers, which include the emergency brake lever and the sliding gear lever; (b) the steering wheel with spark and throttle levers thereon; (c) the pedals, comprising clutch, service brake and accelerator control. In each case the direction of motion is shown by arrows, and it will be seen at a glance that there is a wide divergence between them, if indeed it may not be said that there are no two alike.

It would be the height of folly at this time to proclaim in favor of any of the methods illustrated. It is even a question if any coterie of men are mentally equipped to dispose of this broad and important matter on a basis of merit. In a sense, the worst one of the lot, as a standard for all, would have a masterly advantage over the present arrangement, and the chances are that a "compromise" is all that will ever be arrived at as a final disposition of this problem.

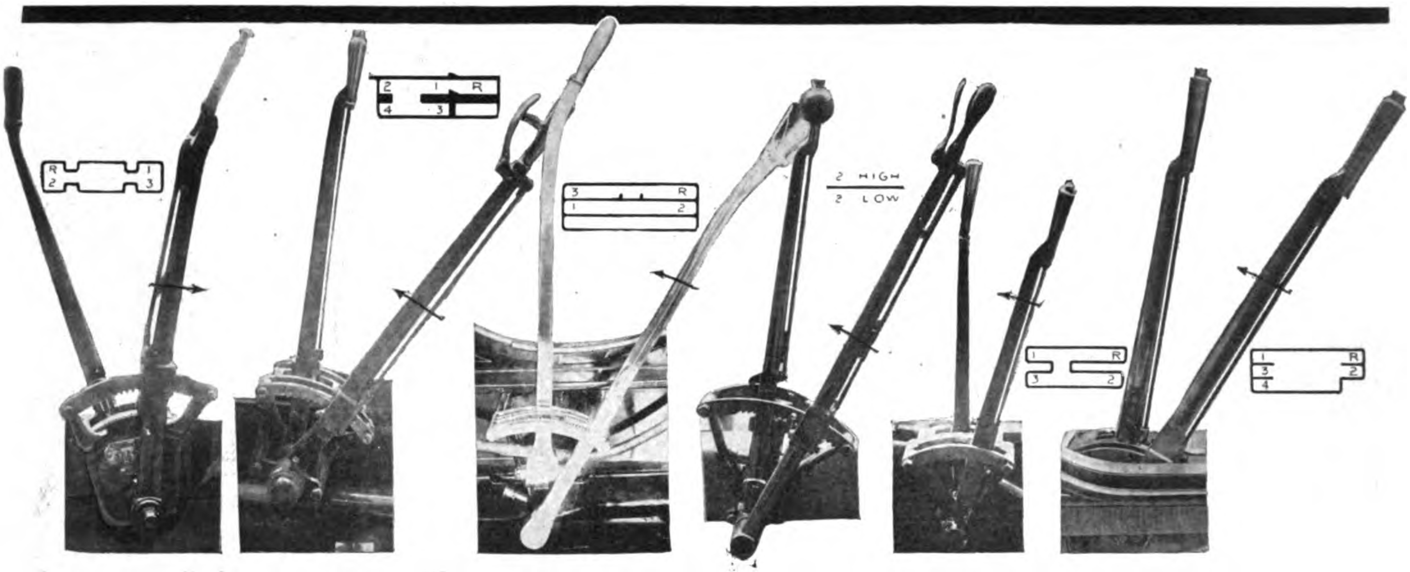
Just to indicate that it is not feasible for designers to make a "Chinese copy" of all the good points in the several examples of automobiles with a view to the production of one superlative car, it will suffice to say that this plan was brilliantly executed on a few occasions, but the mess of junk evolved failed to please those who were expected to support such a brilliantly conceived scheme. When a designer trades off his individuality for a mess of spineless pottage, his inharmonious aggregation ceases to find favor. One of the dangers encountered in the advocacy of a plan of standardization is represented in the influence against individuality, a price is put upon the head of the advanced designer, and the influence is against the highest obtainable average result. But the horizon, from the point of view of the standardization of the automobile, is no darker than it was when railway standards were brought to the fore. The men who will have to agree upon standards are no less capable than the master car builders of former days, but the necessity for action is possibly more acute than it was in connection with railways, one reason for which lies in the fact that railway trains were guided by bands of steel and railway locomotive drivers were men of skill, born of definite training. It is a far more serious matter to place an automobile at the disposal of a man of comparatively little training, and permit him to travel where he will, unrestrained by aught but his own inclination, and it is a self-evident fact that the risk can only be reduced to a minimum if the training which he receives at the start becomes the basis of habits which will stand him in good stead when the emergency arises.

Grading of Materials Rapidly Going On

When the Mechanical Branch of the A. L. A. M. was organized, it was then recognized that nothing could be profitably undertaken in the direction of the standardization of automobiles without having standardized materials to work up. The makers, in getting together and forming a mechanical branch, indicated in this act that many reforms were necessary, and they recognized the difficulties at every hand that beset the purchasing agents of the respective companies. Of the materials that demanded first attention, it is likely that steel was the most conspicuous, and it did not take long to find out that alloy steel, while it offered excellent possibilities, was not wholly to be relied upon in every emergency. When alloy steel first came out, and it found lodgment in many foreign automobiles, they, as they were used in America, proved to be most unreliable in many ways. Broken crankshafts were quite common, and observation did not have to be penetrating to allow of the conclusion that the harder grades of steel had limitations. The modulus of elasticity is probably no higher in alloy steel than it is in ordinary grades, and, when crankshafts are made of alloy steel, they have to be of the same diameter as though they are made of carbon steel. The price of alloy steel is six times higher, and it becomes a question as to whether or not it fills the bill under all conditions—the engineers of the companies, in meeting, settled this matter.



PEDALS ARE WITHIN STRIKING DISTANCE OF A STANDARDIZED CONDITION



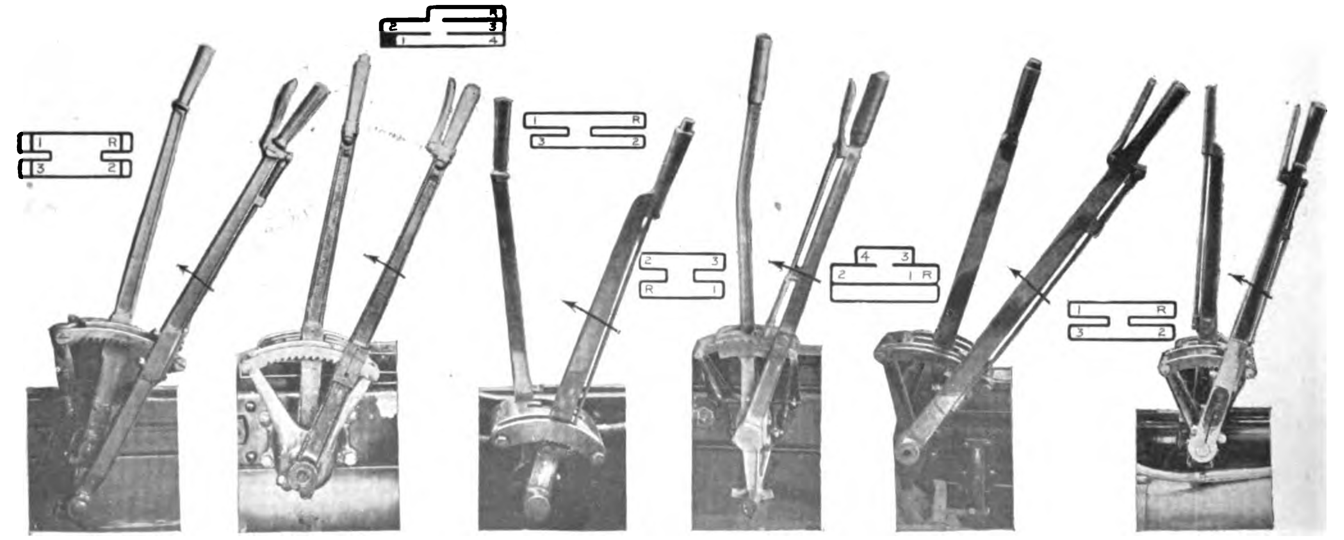
Rambler 45 H.P. 1910 Pierce-Arrow 48 H.P. 1910 Franklin 28 H.P. 1910 White (Gasoline), 1910 Hudson, 1910 Winton 48 H.P. 1911

DOUBTLESS the growth of the automobile industry in America represents a mode of procedure that has no precedent. Other arts, while they attain conspicuous proportions in time, do not compare favorably with the situation as it obtains with the automobile, which, in a decade, revolutionized methods of transportation. That merit is the basis of automobile success is never questioned, but it must be remembered that the vast amount of work done in the evolutionary process required an unusual array of facilities, and in the final sum-up from an historical point of view accessory makers must be given credit for a large proportion of the good work done.

The enormous output of automobiles comes from the combined efforts of the makers of cars and the makers of accessories. The acknowledged superlative quality of American automobiles is traced back to quantity production on a jig basis, favored by specialization at the hands of those who devote themselves to some one phase of the problem. As a general rule a machine reaches its highest state of perfection if all its components are made under the eye and direction of some one competent head, but when the undertaking passes beyond the domain of a single individual the same principle for success can only be perpetuated if the units of the machine are separated out and the influence of the specialist is brought to bear upon them respectively.

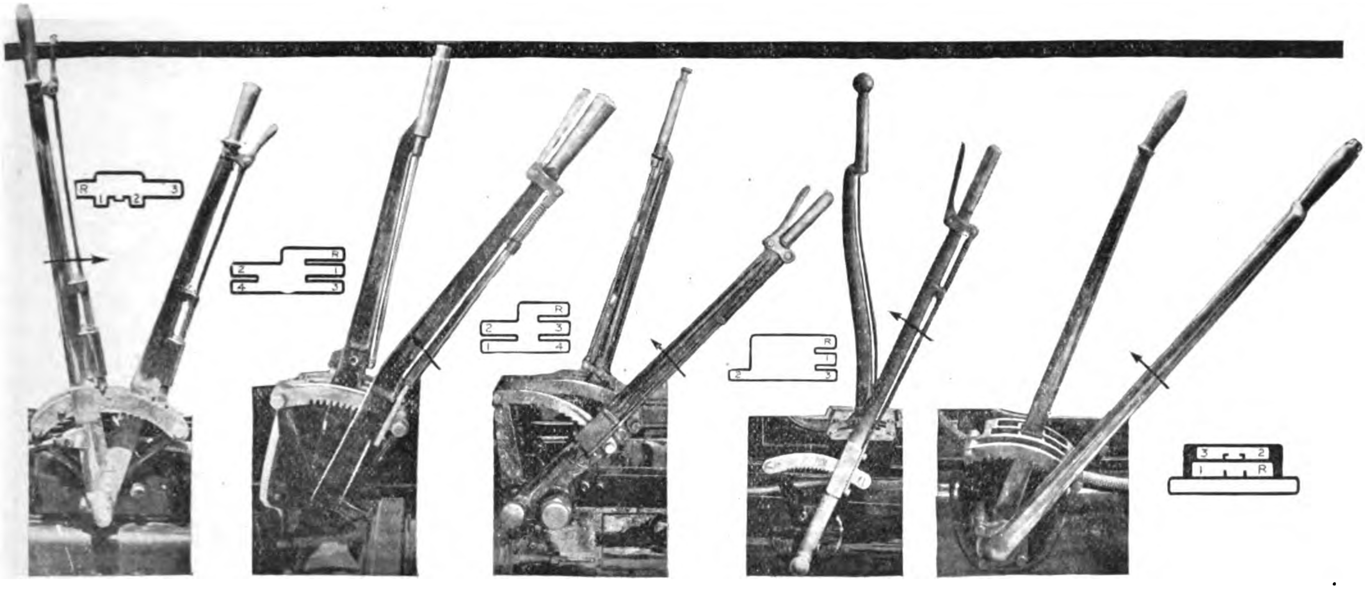
That the making of automobiles has passed beyond the point where any one man can know of all the things that are being done is a self-evident fact, but it is reasonable to accept the version that is presented by the advanced accessory maker in which the claim is made that the work is on a specialized basis and the details are executed under direct command or as the result of an intimate understanding.

To what extent the output of automobile plants was increased by calling upon the accessory makers to anticipate is difficult to fix, but it is a fair claim that there is not a single make of automobile turned out that is entirely free of accessories of one kind or another. True, some makes of cars are almost completely produced in the makers' plants, but even they rely upon outside sources of supply for magnetos, tires, perhaps carbureters, and



Cadillac "Thirty," 1910 Alco "Sixty," 1910 Regal "Thirty," 1910 Columbia 32 H.P., 1910 Stearns 30-60, 1910 Matheson 50 H.P., 1911.

SIDE-LEVERS ARE GREATEST OFFENDERS IN THE SCHEME OF STANDARDIZATION



Stevens-Duryea Model X, 1910 Peerless 50 H.P., 1910 Lozier, 1910 Knox 40 H.P., 1910 Buick 24-30, 1910

not infrequently bodies. Other manufacturers of automobiles resort to the co-operation of accessory makers on an increasing basis, and finally there are products which rank as mere assemblages in which accessory makers furnish the units and parts complete.

Not infrequently arguments are presented, mostly by those who have but a passing acquaintance with the intricacies of the situation, which have for their basis the idea that automobiles are perfect in proportion as they are built without the aid of the accessory plant. Obviously, the maker of an automobile gets what he pays for, and if he selects the highest grade of accessories for use on the type of car he puts out, the car will reflect the high quality of the accessories so produced. If, on the other hand, the car is not to be a good one, and the accessories are purchased because they are low-priced, they will no doubt conform to the requirement.

In the process of standardization accessory makers are doing more perhaps than they are given credit for. As an illustration of the influence of the accessory maker on standardization, it is only necessary to call attention to the fact that in so far as some one make of live rear axle is adopted by 10, 20, 30 or 50 makers of cars, the process of standardization is advanced; likewise, if a given make of motor is adopted by many makers of cars, the process of standardization will be present to whatever extent the given make of motor is put into circulation.

The great underlying question comes with the consideration of the raw materials used by the respective accessory makers, it being the case that if there is no standard to go by, each accessory maker independent of the other will suit his own convenience or consult his personal ideas, under which conditions the materials will vary over the wide limits of the market, and to some extent price will be the governing factor, whereas when a standardized condition is recognized the question of the cost per unit of the material ordered will be reduced to a mere matter of bookkeeping, for if there is a standard set for the quality of the material there will be a standard price as well.

History, Growth and

WITH its absorption of the Mechanical Branch of the Association of Licensed Automobile Manufacturers the Society of Automobile Engineers came into its proper sphere of usefulness and importance with relation to the development of the automobile.

This great step in a progressive way was not accomplished in a day or a year. It followed after the Society of Automobile Engineers had been in existence for over five years, and it resulted from conditions that had been changed by its efforts. These changes took place gradually, but with a cock-sure certainty that made a forecast of the actual happening something more than guesswork.

The Mechanical Branch of the A. L. A. M., composed of engineers employed by members of the association in the building of automobiles, did a great work, and had a distinct purpose in life, but the time eventually came when its purposes would best be served by a disinterested association such as the Society of Automobile Engineers, to whom the work was turned over.

To-day the society, as it stands, represents the soul of the automobile business in the United States. From it come the impulses that make for advancement along structural and mechanical lines. With a membership a little short of 300, it includes the most advanced thinkers and workers in its field of endeavor, which covers the greatest and most important item in modern commerce—the automobile.

As a single example of the work already performed by the society, attention may be directed to the earnest, painstaking labor which resulted in the introduction of alloy steels into the manufacture of American automobiles. If the only claim of the society upon fame was bound up in this single item its results have been sufficiently important to justify the society in living indefinitely.

In a score of different ways it has proved its value and its practical availability. Founded upon a creed of the highest ethical character; trammeled by no stringent commercial limitations, the society is free to delve into research; to experiment, theorize, discuss, and with the utmost latitude, to reach conclusions.

The engineering problems that arise in manufacturing: the basic development of the automobile and the fundamental principles of mechanical art, all come under the scrutiny of the society. The theses read at its meetings and the discussion that arises from them, go clear to foundation axioms of mathematics and the structures built upon these foundations extend far and away beyond the lines of present practice.

As an illustration: Several years ago, during the period when ordinary steel was being used freely in the manufacture of automobiles, in America, the society kept a watchful eye upon experimental work with alloyed steel in Europe. Detailed experiments were made and the value of the alloys was demonstrated by the work of the scientists. There was sharp protest from the manufacturers of steel in the United States, and much opposition was developed against the introduction of the improved metals in the making of American automobiles.

It was difficult to arrange for the first importation of fifty tons of this material, and when the shipments became so large that they could not be ignored by the foundrymen, the American steel trade bowed to the dictum that had been pronounced in favor of the alloyed steels and the effect upon manufacture of motor cars to-day is emphatically felt throughout the country.

The history of the Society of Automobile Engineers covers a little more than five years. Along in the Spring of 1905 a

PROGRAMME

THURSDAY—9 A. M.

The Society of Automobile Engineers—the lines along which the organization may be made of the greatest value to its members individually and to the motor car industry.

The Society Constitution and Its Limitations.

Suggested amendments to the Constitution, which may facilitate the practical work of the Society.

The Publication of a Digest of Technical Literature.

The Conduct of a Reference Library.

2 P. M.

The Specification and Heat Treatment of Automobile Materials. Address by Mr. Henry Souther.

The Test of a 20-Horsepower Franklin Air-Cooled Motor. Conclusion of paper by L. R. Evans and R. P. Lay. By Prof. R. C. Carpenter.

Variation of Current Practice in Anti-Friction Bearings. Paper by D. F. Graham.

The Pyrometer—Its Development and Use. Paper by W. H. Bristol.

Hardness of Metals. A. F. Shore and H. G. McComb.

Lessons to be Learned from the Motor Car Contest.

Drive-Shaft versus Rear-Wheel Brakes.

Three-Point versus Four-Point Suspension.

AFTER SOCIETY DINNER

Report of Committee on Tire Efficiency. By F. J. Newman, Chairman.

Report of Committee on Gear Steels. Dr. G. W. Sargent, Chairman.

The Basis for Motor Car Taxation. Charles Thaddeus Terry.

The Establishment of a Court of Patent Appeals. By E. J. Stoddard.

How to Make Gears Quiet by Grinding. Frederick A. Ward.

The Responsibility of the Motor Car Engineer to his Company and to the Public.

FRIDAY—Afternoon (on Shipboard)

Seamless Steel Tubes and the Necessity for Standardization in Their Specifications. By H. S. White.

Slide, Rotary and Piston Valves versus Poppet Valves for Gas Engines. By Eugene P. Batzell.

Ill-Smelling and Smoky Exhausts. Paper by F. D. Howe.

Wheel Alignments—Camber and Foregather.

Hot Rolled Gears (Teeth Rolled in) for Transmission and Differential Purposes.

Best Tooth Form for Quiet Gears.

Valve Seat Angles.

THURSDAY

9 A. M.

Business session, President's address and reading of reports, followed by a general discussion of announced subjects.

2 P. M.

Professional session.

7 P. M.

Society dinner, followed by a professional session and general discussion.

Subjects not scheduled will come up during the dinner, at which time it is expected that all the members will be present, and in a receptive mood.

Midsummer Meeting

Work of the S. A. E.

handful of progressive scientific men recognized the utility of an organization of automobile engineers, in which nothing but the advancement of practical science should have any weight or influence. These men, among whom were H. M. Swetland, president of the Class Journal Publishing Company; A. L. Riker, vice-president of the Locomobile Company of America; Henry Ford, president of the Ford Motor Company; E. T. Birdsall, A. H. Whiting, L. T. Gibbs, H. P. Maxim, H. F. Donaldson and Henri G. Chatain, representative engineers, attended a preliminary meeting which eventually resulted in the formation of the Society of Automobile Engineers.

PROGRAMME

SATURDAY—9 A. M.

Motor Trucks for Railroad Service. Paper by T. V. Buckwalter.

Test Data Upon Sheet Metal Frame Sections. By L. R. Smith.

Proper Power and Speed for Gasoline Motors for Truck Purposes, and Proper Road Speeds for Vehicles of Different Capacities.

Location of Motor for Commercial Vehicle Work—in Front Under Bonnet or Under Seat.

Long-Stroke versus Short-Stroke Motor—Advantages and Disadvantages of Each.

Driver's Seat on Left versus Driver's Seat on Right for Commercial Car Purposes.

The Edison Battery in Practical Vehicle Service.

Electric Vehicle Mileage.

Foolproofing the Commercial Car Mechanism and Its Control.

Standardization Possibilities Within the Commercial Car Field.

A Proper Nomenclature in the Distinction of Freight and Passenger Vehicles.

Tire Mileage and Costs.

1 P. M.

Nomenclature of Motor Car Parts. Paper by F. E. Watts.

Driver's Seat on Left versus Driver's Seat on Right for Pleasure Car Purposes.

Leaf Springs, Methods of Mounting and the Treatment of Springs by the Manufacturer and in the Hands of the Motor Car Owner.

G. E. Merryweather

The object of the society, as set out in its constitution, was to promote the arts and sciences connected with engineering and mechanical construction of automobile vehicles.

The method by which this object was to be attained was to hold meetings for the reading and discussion of professional papers, for social intercourse, the publication and distribution of its papers and discussions and the maintenance of an engineering library.

The industry was emerging from its swaddling clothes when the society was brought into existence, and the keynote that was sounded at its early meetings found a protesting echo from the infant industry. Up to that time it had been the practice to take several European models and strike a kind of mean average in the building of motors, the construction of running parts and the general architecture. The result was not much more than a mean average, and pretty mean at that, although even in that early day of the industry some creditable advances were made along structural lines.

FRIDAY

9 A. M.

Visits to various manufacturing plants (members to elect three plants which they individually desire to visit; Parties will be grouped accordingly).

1 P. M.

Boat trip as guests of the Timken-Detroit Axle Company, during which there will be a professional session on shipboard, followed by a general discussion of several subjects.

EVENING

Social session, with dinner at Light House Inn for those attending the convention and the ladies accompanying them.

The early activity of the society was marked by no splurge and noise, but a vast amount of conscientious work was done by its members. Its growth was steady from the first, and it soon gave evidences of its permanency. Mr. Riker was chosen first president, and under his administration the foundation was marked out for the great structure that now stands upon it. During the first year a considerable portion of the effort of the society was devoted to perfecting its organization and preparing for its work. At the end of the first year of formal operation Mr. Riker was re-elected as presiding officer, with Henry Ford, vice-president; John Wilkinson, second vice-president, and E. T. Birdsall, secretary-treasurer. A. H. Whiting, L. T. Gibbs, H. M. Swetland, H. P. Maxim, W. H. Alden and H. Vanderbeek were selected as its Board of Managers.

The society had now grown to nearly 100 members, and at its second annual meeting, which was held in New York, January 17, 1907, papers were read by Thos. J. Fay, E. E., on "Some Features of Construction"; by Thomas L. White, on "Alcohol as a Fuel for the Automobile Motor"; by Henry Hess, on "Automobile Change Gears and Their Journals," and by Henri G. Chatain, on "Some Facts Pertaining to Electrical Ignition."

Mr. Fay's address outlined the purpose of the society with much clarity. In introducing his subject, he said: "In attempting to elaborate upon features of construction of motor cars, the dominant idea will be to discriminate as between things tried out and found wanting, things tried out and found satisfactory, and things in the air, so to speak.

"It is believed a society of engineers, to serve a useful end, should act as a 'clearing-house' for engineering practices, rather with the expectation of ultimately fixing upon standards to go by. It is not the purpose here to advocate any scheme likely to limit the zone of activity of inventors, or place one in the position of having to conform to narrow conventions.

SATURDAY

9 A. M.

Professional session, at which Commercial Vehicles will be the main topic, followed by the reading and discussion of several papers.

1 P. M.

Professional session and general discussion of subjects.

ADDITIONAL SUBJECTS FOR DISCUSSION

Cylinders; crankshaft bearings; cylinder heads; valves; piston-rings; cooling; gasoline; noises; brakes; gear-box forms; number of cylinders; fixed ignition; multiple sparking; gear ratios; rear axles; stock cars; worm drives; relation of power to demands.

"On the other hand, it is feasible to aid invention and broaden the range of vision by limiting the amount of details to be mastered, as well as decreasing the repetition of errors, costing, as they do, lives and money."

Mr. Fay then pointed out the supreme advantages of critical consideration and discussion in their relation to condemnation of bad practice and unsound theory.

He presented an advanced view of the use of alloyed steel, recounting his conclusions from a series of exhaustive experiments with nickel-chrome steel. He called attention to the dangers of excessive phosphorus and sulphur in certain varieties of metal used in the composition of this sort of alloyed steel, and gave the figures of his tests in great detail.

After showing the advantages of chrome-nickel steel, Mr. Fay concluded that the price of steel is no sign of its quality, and that good carbon steel at 2 cents a pound was better than bad chrome-nickel steel at 20 cents a pound. He also said that nickel steel, while holding some good qualities, was too uncertain in the stage of development that obtained at that time for use in cars of pretension.

He cited a particularly interesting incident where the carbon steel shaft of an expensive foreign car under his observation twisted in service and said that the engineer, figuring on a much higher elastic limit than was justified, had used carbon steel instead of chrome-nickel steel of the type used by a competitive maker.

He sounded a note of warning against the use of too light aluminum in crank cases and transmission cases, and pointed out the advantages of bronze for those purposes.

"Alcohol as a Fuel for the Automobile Motor," a subject close to the automobile craft, and one that will probably occupy much attention in the years to come, was treated by Thomas L. White.

In introducing his subject, Mr. White said that the economic conditions which must eventually obtain in motordom as to the use of alcohol for fuel, must be considered independently of technical considerations. He pointed out that gasoline is a by-product of a geographically limited and monopolistically controlled industry, and that the whole available and prospective supply is more than mortgaged by the wide demand.

He showed that alcohol could be manufactured almost anywhere for 5 cents a gallon, and that in the view of supply, the conditions were more promising than those that obtained in the gasoline line. He called attention to the fact that if the technical difficulties that stand in the way of using alcohol in place of gasoline could be removed, the demand created for alcohol will be satisfactorily met as to quantity, quality and price.

Mr. White showed by a series of experiments that alcohol requires 6 per cent. of its caloric value to complete its evaporation; that with ordinary compression the inflammation rate of the motor alcohol is sluggish as compared with gasoline; that a 10 per cent. addition of water lends itself to a compression of 150 pounds and upward; that in process of inflammation it does not radiate heat so rapidly as gasoline; that it is most efficient when the walls of the cylinder are maintained at 200 degrees Fahrenheit, and that the penalty for incomplete combustion is corrosion and destruction of valve seats and exposed parts, as well as loss of power.

He pointed out that the aim of the engineer should be toward perfect carburetion with the aid of exhaust heat; acceleration of the inflammation in the cylinder and the maintenance of the heat of the cylinder walls at 200 degrees. He said that in slow-going motors the use of fuel alcohol had proved a success, and suggested that future work in this line should be to carburate air with alcohol, instantly, and to promote approximately instant inflammation at maximum compression. He proposed that air containing partly atomized and partly vaporized alcohol be passed through a layer of calcium carbide before the mixture enters the cylinder. The 10 per cent. of water in the alcohol mixture would generate acetylene gas and the heat thus generated would evaporate the alcohol. He expressed the hope that the future would demonstrate in practice the utility of the idea.

The paper of Henry Hess, on "Automobile Change Gears and Their Journals" was another important address. Mr. Hess went clear to the roots of the problems involving ball bearings. He outlined the best practice of the day, and showed the trend that development must take both here and abroad. How thoroughly justified were the conclusions of Mr. Hess may be realized when it is considered that the ideas he advanced then seem almost like the regular specifications of to-day.

Mr. Chatain's address on "Some Facts Pertaining to Electrical Ignition" detailed a series of tests with the low-tension magneto and high-tension coils, which was an authoritative statement of the most advanced ideas of that day.

At the next quarterly meeting of the society, which was held at Buffalo, a series of papers was read by J. M. Ellsworth and Thos. J. Fay, on "Some Micro-Structural Considerations," on "Pointers on the Equipment of a Hardening Room," by J. G. Schaeffers, on "Construction of Motor Vehicle Springs," by J. G. Rumney, on "Influence of Acid and Rust on Ball-Bearings," by Henry Hess, and on "The Carbureter and Its Functions," by Charles E. Duryea.

The program was composed of strictly technical presentations, and marked a distinct step in the life and progress of the society.

The next meeting was the third annual convention of the society, and was held in New York. The program included addresses by Henry Hess, on "Automobile Hub Bearings"; H. W. Alden, "Some Notes on Taper Roller-Bearings"; J. M. Ellsworth and Thos. J. Fay, on "Usually Unobserved Refinements of Construction," and by Thos. J. Fay, on "Nature Hard Gears."

The following officers were elected: President, Thos. J. Fay; first vice-president, Henry Ford; second vice-president, E. T. Birdsall; and treasurer, Henry Hess.

The transactions of the society began to broaden in scope and influence, and during the year that followed a vast number of important subjects were considered, presented and discussed. The quarterly meetings were held in various cities, the first being called to order in Boston, second at Detroit and the third at Cleveland. The speakers and their subjects at these meetings were as follows: J. O. Heinze, on "Perfecting Automobile Ignition"; P. M. Heldt, on "The Design and Construction of Crankshafts"; Joseph A. Anglada, on "A Multiple Unit System as a Solution of the Heavy Goods Transportation Problem"; Richard W. Funk, on "Forgings for Automobile Work"; E. S. Foljambe, on "Autogenous Welding and Its Application to Automobile Construction"; Otto Heins, on "Some Recent Developments in Magneto Ignition"; Bruce Ford, on "The Storage Battery in Automobile Work"; Frank Beemer, on "The Unit System of Power Transmission in Automobiles"; A. L. Dixon, on "Increased Efficiency of Single Motor Drive"; H. Vanderbeek, on "The Limitations of the Universal Joint"; Thos. J. Fay, on "What Carbon Does to Automobile Steel," and Leon Lacon, on "What Is the Best Timing."

The breadth of thought included in the foregoing subjects is a measure of the activity of the Society of Automobile Engineers, and shows better than any mere comment the value of such an organization as a moving force in the development of the American automobile.

At the next annual meeting of the society Henry Hess was chosen president, with Russell Huff, first vice-president; B. D. Gray, second vice-president; A. H. Whiting, treasurer, and Alex. Churchward, secretary.

The work started and accomplished during the earlier period of its life was continued and expanded under the administration of Mr. Hess. The deliberations of the society had attracted attention, not only of motordom in America and Europe, but of scientists everywhere, and proposals of a flattering nature were made to the society to join forces with other scientific organizations that were only interested in the automobile from an academic viewpoint. These were declined with thanks and appreciation of their complimentary nature, and the S. A. E., now come to commanding size and influence, stepped forth full grown into the glare of focal interest.

The program for the year included the following speakers and subjects: Lawrence Whitcomb and Thos. J. Fay, on "The Trend of Brake Design"; A. Atwater-Kent, on "What Constitutes Ignition Reliability"; F. D. Howe, "The Economics of Weight Reduction"; William S. Noyes, "An Improved Type of Compression Coupling"; S. W. Rushmore and Herbert L. Towle, "An Indicator with Continuously Rotating Drum"; S. P. Wetherell, Jr., "Standardizing Motor Bearings"; Henry Cave, "Some Practical Considerations in Autogenous Welding." The Summer convention was held at Chicago, with the following program: R. C. Carpenter, on "Test of a Pierce Six-Cylinder Motor"; Edward Sokal, on "Possible Increases of the Weight Efficiency of Storage Batteries"; H. M. Beck, on "Some Points in the Operation and Care of Vehicle Batteries"; Frank H. Floyd, on "Notes on Lubricating Oils"; Alexander Churchward, on "Energy Consumption of Commercial Vehicles"; H. S. Baldwin, on "Electric Cradle Dynamometer—Method for Test of Gasoline Engines."

Thus may be traced the expansion of the society's field of work from first principles to the ultimate refinements and back to first principles again. Each meeting marked a step in advance; each successive consideration of a certain subject carried along the line of thought first laid down and when the limitations had been reached the conclusions were used either to break down what had been deemed a fundamental principle or to strengthen its position as a cornerstone of the great engineering fabric.

At the last annual meeting of the society H. E. Coffin, president of the Hudson Motor Car Company, was elected president; Henri C. Chatain, one of the charter members of the society, was honored with the first vice-presidency, and R. C. Carpenter succeeded to the second vice-presidency. A. H. Whiting was re-elected treasurer and Coker F. Clarkson was named acting secretary.

There was another field of usefulness in view for Mr. Clarkson, who at the time was assistant general manager of the Association of Licensed Automobile Manufacturers, and coincidentally with the absorption of the Mechanical Branch of that association by the society, Mr. Clarkson was made general manager of the society. Permanent offices were secured at 1451 Broadway, New York, and a program of still greater activity is being outlined.

Bound by no commercial or financial limitations, and moved only by the considerations that aim to improve and develop automobile engineering, the future stretches away into pleasant vistas of teeming activity.

Study Depicting the Trend in Torpedo Body Designing

INDICATIONS point in the direction of the torpedo type of body with four doors, thus affording access to the driver's seat on either side as well as access to the tonneau. To accomplish this it is necessary to place the emergency brake and sliding-gear lever amidship in the car, and the steering wheel must be placed on the left side. In addition to an arrangement such as this, the illustrations are of a new design which is intended to serve as a "study" in which will be found a definite interpretation of the trend in its various aspects of the automobile body designing situation.

Among the important refinements indicated is the one which protects the radiator from splashes of mud without in any way interfering with the working qualities of the radiator, nor can it be said that the appearance is otherwise than enhanced. As a further suggestion which will carry weight among veteran tourists, is the idea of making a tire "cellar" beneath the floor of the tonneau, with means of access, which is quick and convenient, possessing the added virtue of a secure lock against the wiles of those who want tires but are reluctant to pay for them.

Arguing in favor of the elimination of appended accessories to the glistening surface of a highly finished body makes it necessary to find a place for each of them. If it is desirable to build a tire cellar for the pneumatics, primarily to get them out of the way, at the same time affording protection against thievery, and the further fact that the direct rays of the sun are intense destroyers of tire life, it is equally desirable to place the gas tank in its own compartment, thus removing an unsightly appendage from the running board, and placing the gas tank where the direct rays of the sun will not shine upon it and add to the risk of an explosion, which is always a possibility if heat is applied to the tank.

A second look at this new design will carry the conviction that the occupants of the front seat are afforded the same protection against the wiles of inclement weather as that available to the occupants of the seats in the tonneau. The front entrances were placed so far back that it was necessary to design the seats so that they could be tilted sufficiently to admit of entering, but this plan permits of overhanging the dash sufficiently to house in the occupants of the seats, and by a special shape of the overhang, even the hands of the driver are protected from drafts of wind, thus permitting him to grasp the steering wheel firmly and to enjoy driving even in zero weather. The shape of the overhang is such that the wind is given an upward trend, and it sweeps away over the heads of the occupants of the front seat, thus giving to them all the protection of a glass windshield with none of the disadvantages, as dimming the vision, when mist forms on the glass.

The fuel problem is solved on a simple basis. It is assumed that an autoist who travels from his place of abode to the point of his destination will desire to come back again. It is also assumed that the best automobile is the one which has the least number of intricate parts, so that gravity feed is resorted to, thus eliminating the pressure regulator. Two tanks are shown.

Progress was made when the torpedo scheme took root in body designing. The idea of affording protection to the occupants of the front seats is one that is appreciated by every autoist of experience, and the shaping of the overhang of the dash so that the "dodger" improvement is incorporated, lends favor to the plan. Then, the scheme which eliminates dust accumulations from the person of the passengers in the rear seats gains a measure of appreciation, but it remains for designers of bodies to devise some plan for storing the tires, acetylene tank, and the other accessories, so that they will not continue to detract from the appearance of the car. Pilferers, who go about purloining accessories from automobiles, are ever favored by the ease with which the accessories can be gotten at, and certainly it is worth while to give them more work if they must be dealt with at all. The body, as here presented, is designed to afford protection in the several ways. The shaping of the front of the hood is protective with an opening just large enough to allow of the passage of the requisite amount of cooling air, and the baffling influence necessary to prevent splashes of mud from entering the radiator and passing back to the machinery.

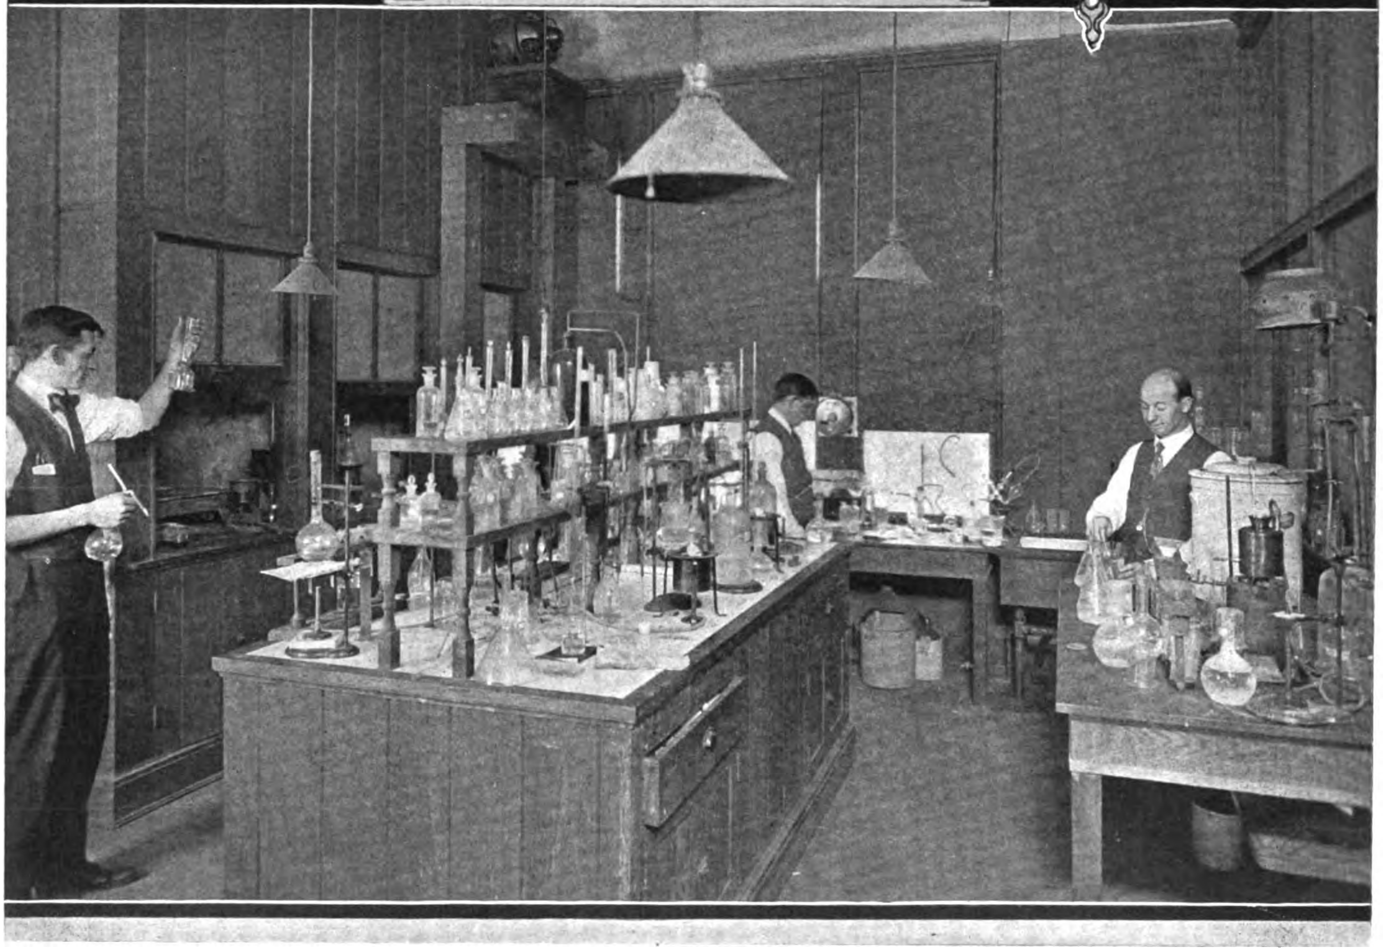
ENGINEERING SECTION

AUTOMOBILE STABILITY STARTS IN THE LABORATORY



NEVER before, in the history of the doings of men, was the time ripe to balance the efforts of the workers in the vineyard of human endeavor. The men whose feet have contact with the "cash box," holding a certain temporary potential standing, were never slow to take advantage of the fact. "Business reasons" were ever at the bottom of loose statements of position, so that engineers, bound down by high aims, and with a proper regard for truth, were kept at the foundation of the structure, there to take the weight of all, with never a chance of correcting the ills which creep in, excepting by primary means reduced to a low state of efficiency as interpreted by business men who are wont to claim that an engineer is not practical.

With the coming of the automobile, and the broadening of the scope of the work that engineers have to do, business men have been compelled to lean more heavily upon the technically trained, and the closer contact has brought about a better understanding and a more healthy combination. The elimination of ruinous competition has had a wider influence upon the newer movement than most economists are ready to admit. As business is now done, it is not necessary to engage a "confidence man" to represent a company, and merit is the most prized stock in trade. Companies are fast learning that merit is not a companion to "sharp practice"; they also find that engineers are not to be depended upon to do a task excepting in the right way.

In the old days men were prized as they showed capabilities in the direction of making purchasers believe that black was white if the exigency demanded. Under the new conditions it only remains to deal with purchasers who are not color blind. Merchandise is produced and sold for what it is, and customers are relied upon to order what they want, so that misrepresentation is no longer necessary. This newer condition, however, has introduced a demand for more skill on the part of the men who do the work just in proportion as the demand for "slick talking" is falling off.

When it comes to doing things as they should be accomplished, there is no chance of being able to improve upon the methods that engineers learn, not only at the universities, but in the shops also. When a man starts out to build a machine of any sort he must be sure of his ground and design all the parts so that they will fit together. This necessity is so pressing that every man engaged in this character of undertaking fully appreciates the advantage of being honest with himself, knowing that if he neglects to take every factor into account the machine will fail to go together and he will have to pay the price of his disregard of first principles.

This drilling along lines that bespeak accuracy has a wide influence on the men and they are continually baited along the paths of honesty of habit and good intention. That this character of man is venturesome enough to suit the type of financier who wants to succeed on a basis of merit is too plain to be denied, and that the engineer will be of any use to the dishonest business man is impossible to believe.

The idea, then, that engineers have to be kept out of the business office because they are not "cute" is being given up. They are wanted there for the very reason that they know better than to deceive themselves, and a man who has this quality as a fundamental basis is the character of man who will not stoop to the point of deceiving his employer or the patrons of that employer.

The claim that the engineer is not progressive enough for business is refuted by the large amount of profitable business that is being done in the many walks of life, nearly all of which is based upon engineering effort. If a company must engage an engineer to design its product, and if the company admits that the engineer succeeds in doing so, he must be held responsible for the result of his handiwork, but he must be given credit for the good that comes therefrom. All the epoch-making advances along constructive lines, of which our form of civilization has any knowledge, are based upon engineering. The workmen who construct machines, whatever they may be, as locomotives, etc., follow the specific instructions of engineers, but this point is frequently overlooked, owing to the fact that the instructions are given in the form of drawings, specifications, rules and regulations.

All the careful work involved in bringing out an equipment is done under the direction of a competent engineer if the equipment is to perform in a proper and satisfactory manner. Just at this point the business office, not being able to discriminate between careful and systematic work as compared with spectacular executional manoeuvres, allows the initial painstaking effort to sink out of mind, but being unable to get away from the loud talk of the man who merely directs the execution of the work in the manner as laid down by the engineer, the conclusion is soon reached that all the push and energy and business acumen emanates from the character of the man who is keen enough to see that he must use the engineer's basis, but who makes enough fuss in the process of doing the work to swing the limelight so that it casts its beam upon his favored brow.

The coming of the automobile, while it is not to be held wholly responsible for the many reforms that are being made, has had much to do with the process of crystallization, and business men of the class who make a success of their endeavors are reaching the conclusion that there is nothing to be gained by traversing the road which is said to be the short cut to victory. When a business is traveling in the wrong direction, the shorter the road the quicker it goes to ruin. When a business is in the hands of the character of man who cares nothing about merit, the more energy he puts into the enterprise, and the more vim he offers as a fair exchange for his stipend, the greater will be the splash the wreck will make when it lands in the sea of oblivion.

The elimination of competition, then, is a step in the right direction. When a man faces ruin, let it be from competition or from any other cause, he is compelled to either throw up his hands or surround himself with the character of talent that is willing to rise to the occasion by stooping low enough to hold an advantage over his competitors who also pride themselves on their ability to stoop. It was called "business expediency;" it was not very different from a rather sad piece of business known as "political expediency," and in these days of straight business the right name is well understood—it is called "dishonesty."

The modern trend leads to the recognition of the man who depends upon his skill to produce results. The greatest step toward this fitting situation was made when it was decided that competition is dishonest because it demands dishonest methods to make it possible to survive, but in substituting a merit basis, which was bound to follow when the selling price was based on the cost plus a profit, it became necessary to employ men who are capable of performing an excellent service, in other words, engineers, it being the case that the word "engineer," viewing it broadly, is descriptive of a man of skill; nor does it make any difference whether he devotes himself to the building of a pyramid, battleship, bridge, an act of congress, or an automobile. The man of skill is in contrast with the character of man who was relied upon under the old conditions in just proportion to the lack of skill of the latter, he relying upon his high disregard of fair dealings, having in view the one idea, "get there."

During the early days of automobile building there were a large number of failures, owing to the lack of appreciation of the facts as herein roughly submitted. The engineering staff was overshadowed by the sales department and the business office, the questions of competition took precedence over the matters of quality, and the heads of these companies, lacking in keenness of vision, failed to appreciate the new spirit and fell by the wayside enmeshed in the warp of cleverness, disregarding the woof of substantiality.

Under the old conditions, the engineers beggared along, made the best showing they could in the face of little encouragement, were honest with themselves in that they performed their part of the service in the light of their high ideals, saved cost wherever it was possible to do so without reducing quality, and kept before them, in so far as they could, the main point of view. Failure came when the purchasing departments disregarded the specifications for materials, and bought cheaper stuff. If anything but disaster can follow after such an act it must be by accident. If an engineer decides that the extreme fiber strain, for instance, of a crankshaft will leave a factor of safety of four if chrome nickel steel is used, but if the purchasing agent substitutes an ill-contrived forging out of a Bessemer bar, the latter can only be charged with having listened to the wiles of the vender's "slick Sam" who had a surfeit of Bessemer forgings to get rid of, and knew enough to go to a company whose management lacked in sense, thus permitting an ignorant purchasing agent to abort the efficient labor of an intelligent engineer by a process no more intricate than the deliberate purchase of the materials which are not wanted, for no better reason than that the vendor wants to get rid of them and is willing to name a low price.

These evils have been largely corrected. To-day the purchasing agent is not infrequently a skilled metallurgist; he studies the engineer's specifications, has the drawings before him when he takes up the matter for consideration, and while he acts on his own initiative, he nevertheless appreciates the reasons why the engineering office puts out specifications and works over designs until they are perfected. The modern purchasing agent, having an engineering training, tells the vendor what he wants, using fitting language in his description, and ascertains the price of the product which will suit his purpose, with never a thought of stocking up on "white elephants." This new way of conducting the automobile business is the cheapest in the long run; it eliminates wasters, shrinks the junk pile to insignificance, hastens the delivery of the finished product, commands a higher price, and makes every customer a willing, animated advertisement.

The Prediction of Efficiency in Internal Combustion Engines

By WILLIAM D. ENNIS, Professor of Mechanical Engineering in the Polytechnic Institute of Brooklyn.

The efficiency of the internal combustion motors is predicted rather than to design and build the motor, and then find out how good it is. Comparison is made with the idealized Otto cycle. Basic formulæ are given and the workings of the same are exposed. Application to the design of the automobile type of motor is made.

An advance estimate of the probable economy of a steam engine may usually be made on the basis of experimental data. Of these there are an abundance, for all sizes, types and forms of engine. A computation of probable efficiency on theoretical grounds is usually less satisfactory. The factor of cylinder condensation is so uncertain that in this respect alone the method must be based upon bold assumptions, the only justification for which is found in the records of those very tests which should enable us to form a more direct prediction.

With the internal-combustion engine the case differs. Here we have not only a comparatively insignificant number of test records, but with a few exceptions designs are so far from standardized that it is impracticable as yet to systematically classify those results which we do possess. Fortunately, a purely theoretical estimate is possible. In this, it is true, certain assumptions must be made; but the accuracy of our knowledge of these factors surpasses that which we have of the quantitative effect of such matters as condensation in the steam cylinder. Moreover, the error in the final result is of inferior order to those involved in most of the necessary assumptions.

Let an internal-combustion engine have a piston displacement of D cubic feet per minute; let it be supplied with a mixture of fuel and air in the proportions A and B, by volume, parts in 100. Then the volume of fuel supplied per minute is, in cubic feet,

$$0.01\,AD.$$

Referring to Fig. 1, which represents the idealized Otto cycle with the suction and exhaust strokes omitted, the cylinder is full of the mixture only along the line 4 1. We may readily calculate the specific volume of this mixture if the temperature and pressure at either 4 or 1 be given. We may also find, from the same data, the specific volume of the fuel, separately considered, at the pressure and temperature existing at any instant when the piston is at the outer dead center and the cylinder is filled with fluid. Let this specific volume (cubic feet occupied by 1 pound of vaporized fuel) be C.

In Fig. 2, let the stroke of the piston be from B to A and let the engine make E strokes per minute. If the piston displacement per stroke be F cubic feet, then

$$EF = D.$$

During each stroke the cylinder is filled with mixture of volume F, and of this mixture the vaporized fuel has the volume

$$0.01\,AF.$$

The weight of fuel trapped in the cylinder at each stroke is then

$$\frac{0.01\,AF}{C};$$

and the total weight of fuel supplied per minute is, in pounds,

$$\frac{0.01\,AFE}{C} = \frac{0.01\,AD}{C}. \qquad (1)$$

Let the heat of combustion of the fuel, per pound, be G, B.t.u.; then the heat chargeable to the engine, per minute, is

$$\frac{0.01\,ADG}{C}, \text{ B.t.u.} \qquad (2)$$

The next step is to find the amount of power exerted by reason of this supply of heat. The diagram of Fig. 1 may serve to represent the indicator diagram obtained from the engine, somewhat idealized. The lines 2 3 and 4 1 may be regarded as vertical, while 3 4 and 2 1 are of a form which may be represented by the equation

$$PV^n = \text{a constant},$$

in which the value of n varies with the piston speed, jacketing and other factors, but is, roughly, about 1.3. Taking the value of n the same for the curve 3 4 as for 2 1, the mean effective pressure of the diagram (average height of the area 1 2 3 4) is, in usual notation,

$$\frac{P_3V_3 - P_4V_4 - P_2V_2 + P_1V_1}{(V_1 - V_2)\ (n - 1)} = H. \qquad (3)$$

Let the engine give E diagrams per minute. The work done, in foot-pounds, per minute, is

Mean effective pressure × *piston area* × *length of stroke* × *number of strokes.*

But *piston area* × *length of stroke* $= V_1 - V_2$, and $V_1 - V_2 \times$ *number of strokes* $= D$; while 778 foot-pounds = 1 B.t.u.; so that the work done per minute, in B.t.u., is

$$HD = \frac{D}{778\ (n - 1)\ (V_1 - V_2)}\ (P_3V_3 - P_4V_4 - P_2V_2 + P_1V_1),$$

and the thermal efficiency, equal to the ratio of work done to heat supplied, is

$$I = \frac{DC}{7.78\,ADG\ (n - 1)\ (V_1 - V_2)}\ (P_3V_3 - P_4V_4 - P_2V_2 + P_1V_1),$$

$$= \frac{C}{7.78\,AG\ (n - 1)\ (V_1 - V_2)} \left\{ (P_1 - P_4)\ V_1 + (P_3 - P_2)\ V_2 \right\}$$

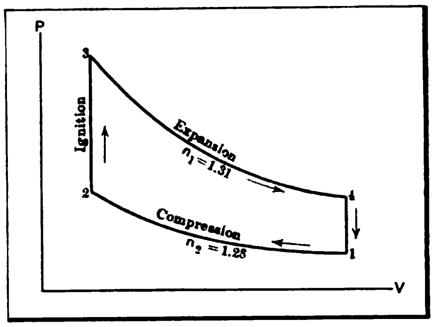


Fig. 1—Indicator diagram representing idealized Otto cycle

Thus far the steps are almost exactly correct: a slight corrective factor to include the effect of irregularities in the actual diagram being all that is necessary to make them strictly accurate. From this point, some assumptions must be made. For a given type of engine there is ample data to permit of fixing the probable value of P_1, the pre-compression pressure. For a given fuel, P_2 is also determined in the design, with considerable exactness. The only serious uncertainty has to do with the value of P_3. We have no complete data as to variations in maximum pressure attained with various forms of engine. So far as is known, the jacketing arrangements are the only controlling factors, and when these are such as to satisfy mechanical operative requirements, the temperature at the point 3 is not far from constant for all engines using hydrocarbon fuels other than producer gas or blast-furnace gas. The pressure P_3 then depends solely on the pressure and temperature at 2, in accordance with the law

$$\frac{P_3}{P_2} = \frac{T_3}{T_2},$$

temperatures being absolute temperatures and ignition instantaneous. With P_2 and P_1 given, T_2, of course, depends upon the values of T_1 and the exponent n. Knowing P_3, we may find P_4 from the relation

$$\frac{P_4}{P_1} = \frac{P_3}{P_2},$$

an equation which holds only when the exponent n is the same for both the curves 3 4 and 2 1. But if $P_3V_3^m = P_4V_4^m$, we readily find

$$P_4 = P_3\left(\frac{V_3}{V_4}\right)^m.$$

In order to find the volumes, we note that $P_1V_1^n = P_2V_2^n$, whence $\frac{V_1}{V_2} = \left(\frac{P_2}{P_1}\right)^{\frac{1}{n}}$.

Then $V_1 - V_2 = V_2\left(\frac{P_2}{P_1}\right)^{\frac{1}{n}} - V_2 = V_2\left\{\left(\frac{P_2}{P_1}\right)^{\frac{1}{n}} - 1\right\}$. This yields

$$I = \frac{C}{7.78\,AG\,(n-1)\,(V_1 - V_2)}\left[(P_1 - P_4)\,V_2\left\{\left(\frac{P_2}{P_1}\right)^{\frac{1}{n}} - 1\right\} + (P_3 - P_2)\,V_2\right]$$

$$= \frac{CV_2}{7.78\,AG\,(n-1)\,(V_1 - V_2)}\left[P_2P_1^{\frac{n-1}{n}} - P_1 - P_4\left(\frac{P_2}{P_1}\right)^{\frac{1}{n}} + P_4 + P_3 - P_2\right].$$

It is usually more convenient to find the numerical ratio of V_1 to V_2;

$$V_1 = \left(\frac{P_2}{P_1}\right)^{\frac{1}{n}} V_2 = \text{say } JV_2.$$

Then by substitution in the first formula for I, we find

$$I = \frac{CV_2}{7.78\,AG\,(n-1)\,(V_1 - V_2)}\left\{J\,(P_1 - P_4) + P_3 - P_2\right\}$$

$$= \frac{CK}{7.78\,AG\,(n-1)}\; J\,(P_1 - P_4) + P_3 - P_2\},$$

in which $K = \frac{V_2}{V_1 - V_2}$ is the *clearance*, expressed in proportion of the piston displacement. The analysis may be extended to cases in which the exponents of the expansion and compression curves have different values. A specimen calculation will show that the method is simpler when handled arithmetically than in symbols.

Application to an Automobile Engine

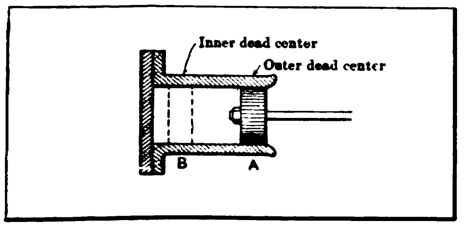

Fig. 2—Sketch indicating position of piston in cylinder at various stages of stroke

Let the fuel be gasoline, its composition being assumed to be C_6H_{14}, and its heat of combustion 22,000 B.t.u. per pound. Let the mixture consist of 38 parts of air to one of gasoline vapor, by volume (the theoretically correct amount of air would be about 46.7 parts), so that $A = \frac{100}{38 + 1} = 2.564$, $B = 97.436$. Let the engine be of the four-cycle, single-acting type; then P_1 may be assumed at about 12 pounds absolute, while T_1 in this class of service may be about 100 deg. F. or 560 deg. absolute. The pressure assumed is in pounds per square *inch*; all pressures will later be converted to pounds per square *foot*. The specific volume of air at any pressure and temperature is given by the formula

$$V = \frac{53.36\,T}{P},$$

which in this instance becomes

$$\frac{53.36 \times 560}{144 \times 12} = 17.29 \text{ cubic feet.}$$

Gasoline vapor is 3.05 times as heavy as air; its specific volume, at the moment when the mixture completely fills the cylinder, is then

$$17.29 \div 3.05 = 5.669 \text{ cubic feet.}$$

The weight of gasoline fed per cubic foot of pistón displacement is then

$$\frac{0.01 \times 2.564}{5.669} = 0.004523 \text{ pound,} \qquad \text{(Equation 1)}$$

and its heat of combustion is (Equation 2)

$$0.004523 \times 22{,}000 = 99.506 \text{ B.t.u.}$$

Tests have shown for the type of engine in question that the value of n for the compression curve 1 2, Fig. 1, may be taken at about 1.28; that for the expansion curve 3 4 may be taken at 1.31. Calling these values n_2 and n_1, the mean effective pressure is given by an expanded form of Equation 3 as

$$H = \left\{\frac{P_3V_3 - P_4V_4}{n_1 - 1} - \frac{P_2V_2 - P_1V_1}{n_2 - 1}\right\} \div (V_1 - V_2).$$

Since $P_1 = 12$, and P_2 in a gasoline automobile engine may be fixed at 75, we find

$$P_1V_1^{n_2} = P_2V_2^{n_2}\ V_2 = \left(\frac{P_1}{P_2}\right)^{\frac{1}{n_2}} V_1 = \left(\frac{12}{75}\right)^{0.781} V_1 = 0.239\,V_1.$$

We then reduce Equation 3 as follows:

$$H = \left\{\frac{P_3V_2 - P_4V_1}{n_1 - 1} - \frac{P_2V_2 - P_1V_1}{n_2 - 1}\right\} \div (V_1 - V_2)$$

$$= \left\{\frac{0.239\,P_3V_1 - P_4V_1}{n_1 - 1} - \frac{0.239\,P_2V_1 - P_1V_1}{n_2 - 1}\right\} \div (0.761\,V_1).$$

To evaluate this, we may assume the maximum temperature T_3 to be about 3,000 deg. absolute (2540 deg. F.). Then

$$\frac{P_3}{P_2} = \frac{T_3}{T_2} \text{ and } P_3 = 75 \times \frac{3{,}000}{T_2}.$$

But by a common law of gases,

$$P_2V_2T_1 = P_1V_1T_2;$$

also

$$P_2V_2^{n_1} = P_1V_1^{n_1}.$$

Combining these two forms,

$$V_2^{1-n_1}T_1 = V_1^{1-n_1}T_2$$

$$\left(\frac{V_2}{V_1}\right)^{1-n_1} = \frac{T_2}{T_1}$$

$$T_2 = T_1\left(\frac{V_2}{V_1}\right)^{1-n_1} = 560\,(0.239)^{-0.28} = 836 \text{ deg. absolute.}$$

Substituting, we find

$$P_3 = 75 \times \frac{3{,}000}{836} = 269.5 \text{ pounds per square inch.}$$

Again,

$$\frac{P_4}{P_1} = \frac{P_3}{P_2},\ P_4 = P_1\frac{P_3}{P_2} = 12 \times \frac{269.5}{75} = 43 \text{ pounds per square inch.}$$

The numerical value of H, the mean effective pressure, is then

$$\left\{\frac{(0.239 \times 269.5) - 43}{0.31} - \frac{(0.239 \times 75) - 12}{0.28}\right\} \div 0.761$$

$$= 62.2 \text{ pounds per square inch.}$$

The same value multiplied by 144 (to reduce to pounds per square *foot*) represents the work done by the engine, in foot-pounds, per cubic foot of piston displacement, and the thermal efficiency is consequently

$$I = \frac{62.2 \times 144}{778 \times 99.506} = 0.1157.$$

Suppose the automobile to be developing an average continuously of 20 horsepower at the cylinder and to be moving at a speed of 22 miles per hour, its rate of work performance will then be $\frac{20}{22} = 0.91$ horsepower-hours per mile. One horsepower-hour is equivalent to

$$\frac{33{,}000 \times 60}{778} = 2{,}545 \text{ B.t.u.}$$

The heat equivalent of the power exerted is then

$$2{,}545 \times 0.91 = 2{,}316 \text{ B.t.u. per mile,}$$

and the consumption of gasoline should be

$$\frac{2{,}316 \div 0.1157}{22{,}000} = 0.91 \text{ pound per mile;}$$

or the machine should travel, with one gallon (5 5-8 pounds) of gasoline,

$$\frac{5\ 5\text{-}8}{0.91} = 6.23 \text{ miles.}$$

Changing the Mixture

Suppose now that by adjustment of the carbureter the engine were given a more nearly correct mixture, say, 44 parts of air to one of gas, so that

$$A = \frac{100}{44 + 1} = 2.213, \quad B = 97.787.$$

The weight of gasoline fed per cubic foot of piston displacement is, then,

$$\frac{0.01 \times 2.213}{5.669} = 0.00391 \text{ pound,} \qquad \text{(Equation 1)}$$

and the heat of combustion chargeable is

$$0.00391 \times 22{,}000 = 86.1 \text{ B.t.u.} \qquad \text{(Equation 2)}$$

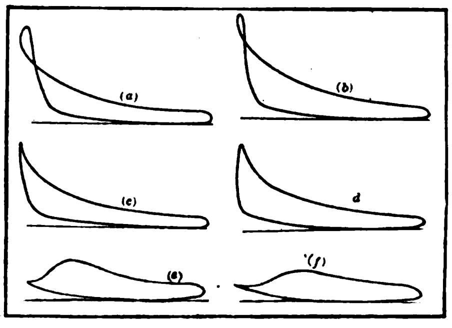

Fig. 3—a, ignition 25 per cent. early; b, ignition 20 per cent. early; c, ignition 16 per cent. early; d, ignition 12 per cent. early; e, ignition 5 per cent. early; f, ignition 10 per cent. late*

If no change be made in our assumption as to maximum pressure, P_3, the mean effective pressure is as before 62.2 pounds per square inch. Theory would warrant the assumption of a higher pressure, P_3, when the air supply is more nearly correct, but in the absence of data in verification of this, we may take the mean effective pressure as certainly not less than 62.2, and the thermal efficiency becomes

$$> \left[\frac{62.2 \times 144}{778 \times 86.1} = 0.134\right].$$

This would make the miles run per gallon of gasoline, under the assumed speed and load conditions, 7.2 instead of 6.23; the efficiency varying directly, and the gasoline consumption inversely, as the proportion of gas in the mixture. As has been stated, this is within the fact.

Altering the Spark

The wastefulness arising from an incorrect spark position is suggested in Fig. 3, which represents the indicator diagrams obtained for various points of ignition. In a, ignition occurs when the piston has only three-fourths completed its return stroke (from A toward B, Fig. 2). In b the spark is a little later, and in c later still. The correct position seems to be attained in d. Here ignition occurs when the return stroke is seven-eighths completed. In e, and more notably in f, ignition is too late; the spark passes after the piston has passed the inner dead center. The area of the indicator diagram is thus much reduced, and since this area represents the work done by the engine, a serious loss of power results. If the engine, when giving the diagram d, with the spark properly adjusted, develops 20 horsepower, it will, when giving the diagram a, develop only 16 horsepower, and the horsepower for diagram f will be only 15. Every variation of the spark from position d decreases the amount of power developed. These decreases, moreover, are *unaccompanied by any decrease in the amount of fuel supplied.* Moving the spark from the ideally correct position is, therefore, always wasteful. Suppose the spark is shifted from position d to position a. The car will no longer make 6.23 miles per gallon of gasoline, but only

$$6.23 \times \frac{16}{20} = 4.86 \text{ miles,}$$

a decrease of 22 per cent.

Throttling

In the ideal cycle of an internal-combustion engine the curves 3 4 and 2 1, Fig. 1, are *adiabatic,* i. e., there is no transfer of heat to or from the mixture while it is working along those curves. In such case, the ideal efficiency is, l standing for the specific heat at constant volume,

$$\frac{l\,(T_3 - T_2) - l\,(T_4 - T_1)}{l\,(T_3 - T_2)} = 1 - \frac{T_4 - T_1}{T_3 - T_2}.$$

But $\frac{T_4}{T_3} = \frac{T_1}{T_2}$, as already found; hence, $\frac{T_4}{T_1} = \frac{T_3}{T_2}$, $\frac{T_4}{T_1} - 1 = \frac{T_3}{T_2} - 1$, $\frac{T_4 - T_1}{T_3 - T_2} = \frac{T_1}{T_2}$, and the efficiency is

$$1 - \frac{T_1}{T_2} = \frac{T_2 - T_1}{T_2}.$$

Since $\frac{P_2V_2}{T_2} = \frac{P_1V_1}{T_1}$, while $P_2V_2^n = P_1V_1^n$ and $P_2^{\frac{1}{n}}V_2 = P_1^{\frac{1}{n}}V_1$, we may write

$$\frac{\frac{P_2V_2}{T_2}}{P_2^{\frac{1}{n}}V_2} = \frac{\frac{P_1V_1}{T_1}}{P_1^{\frac{1}{n}}V_1} \text{ and } \frac{P_2^{1-\frac{1}{n}}}{T_2} = \frac{P_1^{1-\frac{1}{n}}}{T_1}, \text{ or } \frac{T_1}{T_2} = \left(\frac{P_1}{P_2}\right)^{\frac{n-1}{n}}.$$

Also,

$$\frac{\frac{P_2V_2}{T_2}}{P_2V_2^n} = \frac{\frac{P_1V_1}{T_1}}{P_1V_1^n} \text{ and } \frac{V_2^{1-n}}{T_2} = \frac{V_1^{1-n}}{T_1}, \text{ or } \frac{T_1}{T_2} = \left(\frac{V_1}{V_2}\right)^{1-n}.$$

The efficiency may then be written

$$1 - \left(\frac{P_1}{P_2}\right)^{\frac{n-1}{n}} \text{ or } 1 - \left(\frac{V_1}{V_2}\right)^{1-n}$$

It thus depends upon the range of pressure or of volumes during compression and on the value of n.

Now in the actual engine, the curves 3 4 and 2 1 are not adiabatic; the mixture is giving up or receiving heat to the cylinder walls at a rate which is determined by the values of n and the temperature ranges. The heat received along 3 4, in spite of a higher value of n, exceeds that rejected along 1 2, because the temperature range is two or three times greater. The efficiency is thus less than that of the ideal cycle, but the following analysis for the ideal cycle is found to correspond with the results actually attained.

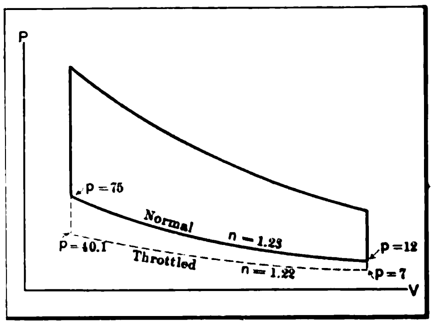

Fig. 4—Normal diagram with dotted lines showing effect of throttling

In an engine once constructed,

---

* From Poole's "The Gas Engine," by permission of the Hill Publishing Company.

the value of $\frac{V_1}{V_2}$ is for all time fixed, and if the value of n were also fixed, the efficiency would be constant for all mixtures and pre-compression pressures. It would be independent of the load. But in practice we find the efficiency to decrease at light loads. There is trapped in the cylinder clearance space (which may be as much as 50 per cent. of the piston displacement) at all times a volume of mixture which at each stroke mingles with the fresh charge. This clearance mixture is hot, hotter not only than the fresh charge, but also hotter than the jacketed cylinder walls. When the suction is throttled, the proportion of fresh charge to clearance gas (by weight) is decreased. The whole mixture is, therefore, hotter than it otherwise would be. It consequently loses more heat to the cylinder walls during the compression stroke than it otherwise would lose. Its pressure and temperature at any moment are then less than they otherwise would be; the compression curve is, therefore, a flatter curve, i. e., the value of n is reduced. In the expressions,

$$\frac{T_2 - T_1}{T_2},\ 1 - \left(\frac{P_1}{P_2}\right)^{\frac{n-1}{n}},\ 1 - \left(\frac{V_1}{V_2}\right)^{1-n},$$

the effect of throttling is to decrease the efficiency. Fig. 4 shows the normal and part of the throttled indicator diagrams superimposed, the latter being dotted. Without considering, for the present, the modifications which might arise as the result of throttling on the upper part of the diagram, let us examine the cases in which (a), as in our former illustration, $n = 1.28$, $P_1 = 12$, $\frac{V_2}{V_1} = 0.239$; and (b) $n = 1.22$, $P_1 = 7$, $\frac{V_2}{V_1} = 0.239$. In the former case we have found that $P_2 = 75$, and the ideal efficiency is

$$\frac{836 - 560}{836} = 0.33;\ 1 - \left(\frac{12}{75}\right)^{0.239} = 0.33;\ 1 - (4.19)^{-0.28} = 0.33.$$

In the latter case, the efficiency becomes

$$1 - (4.19)^{-0.22} = 0.27;$$

or, since

$P_2 = P_1\left(\frac{V_1}{V_2}\right)^{n} = 7\ (4.19)^{1.22} = 40.1$, we may also write the efficiency as

$$1 - \left(\frac{P_1}{P_2}\right)^{\frac{n-1}{n}} = 1 - \left(\frac{7}{40.1}\right)^{0.18} = 0.27.$$

The ideal efficiency is thus decreased 6 per cent. by throttling; the miles run per gallon of gasoline, assuming that the actual efficiency is correspondingly decreased, would drop from 6.23 to

$$6.23 \times \frac{94}{100} = 5.85.$$

Summary

It is thus possible to predict not only the normal efficiency, but also that attained under modified conditions of mixture, spark position and throttle opening. The importance of a proper mixture and the economy of a wide-open throttle are shown, and the wastefulness resulting from unnecessary adjustment of the spark is clearly illustrated.

Vogue of Small Automobiles in Europe

By W. F. BRADLEY

The economical figure for automobiles in Europe seems to be $500; the commercial traveler and the doctor use the diminutive car; single-cylinder motors are preferred; the stroke is relatively long; belt-drive shown in one instance; simplicity is regarded as a companion to convenience of location in these types of cars.

WITH a view to bringing out the trend of the industry in France and England, resort has been had to the camera, and among the illustrations here afforded is ample evidence of the manner in which the question of economy is coupled with utility.

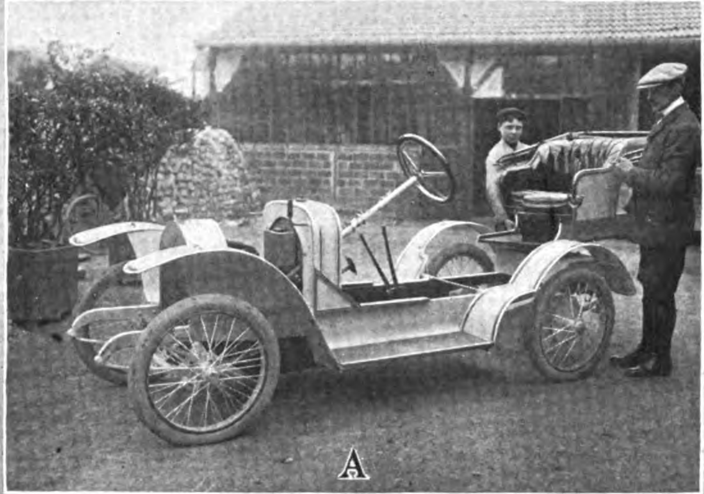
Both France and England are keenly interested in the economical automobile. The economical figure for the European is $500, or not more than $600, all complete for the road. And for this moderate price the Easterner wants something more than a toy; his automobile must be capable of carrying two persons at a fair clip; it must be simple, reliable, cost little to maintain, and, in externals, at any rate, conform to established big car lines. There have been numerous attempts to fill the difficult position, and although some of the designs have been good, they have generally failed through indifferent construction, or by inattention to details.

One of the most promising of these diminutive automobiles intended for the commercial traveller, the doctor, and the man who cannot afford to run a big car, is the Forster, produced by an Englishman resident in France. The automobile, which can be marketed complete for a fraction over $500, has an armored wood frame giving a wheelbase of 84 inches and a track of 40 inches. It is mounted on wire wheels, shod with 700 by 85 tires, has semi-elliptic springs all round, the motor is carried under a bonnet forward, with the gilled tube radiator directly over the front axle, the gasoline tank is on the dash, oil tank under the bonnet, and, so far as its external appearance is concerned, is as graceful a vehicle as any large car yet produced.

There is nothing distinctive about the power plant: on the ordinary models it is a single-cylinder 7-horsepower Anzani or Aster, and on the semi-racing type a two-cylinder Anzani of 15-horsepower. The motor is placed across the chassis, thus making it necessary to crank from one side; the cranking handle is entirely hidden from view. This disposition of the motor is necessary on account of transmission by belt. A broad pulley is carried on the motor shaft and connection made by a long belt with the countershaft, providing two forward speeds and neutral, with final drive taken by single side chain running in an oil-tight casing. There is no clutch, no differential and no gearbox, as that organ is generally understood.

The driver declutches by means of the usual type of pedal, but this operation results in sliding forward the whole of the rear axle, thus slackening off the belt. The necessary movement of the axle is obtained by the use of long spring shackles hanging from a transverse tube projecting from each side of the chassis frame. This length of shackle allows the whole of the axle to be moved ahead far enough to free the belt. Naturally the countershaft has to move with the axle, so that the tension of the chain is never varied, and for further facility the change-speed lever and brake lever are also carried ahead, being mounted on the same frame as the countershaft. As the brake lever operates the rear-wheel brakes through cables it does not become inoperative with the changing position of the axle, the same relative distance always being maintained. Advantage is taken of this movement of the rear axle and countershaft to obtain a very simple brake. Immediately ahead of the driven pulley is a wooden brake block mounted to two transverse frame members. As it is moved forward, still driven by the road wheels and single chain, the pulley is brought in contact with this block and a braking effort obtained in proportion to the pressure exerted on the pedal.

A complete under-pan assures the belt working under ideal conditions; a plank placed immediately under its upper length causes it to drop away from the pulleys on "declutching," and the absolutely oil and dust-proof chain case gives complete protec-



A—Forster light car. Body can be lifted off in 10 seconds without any tools

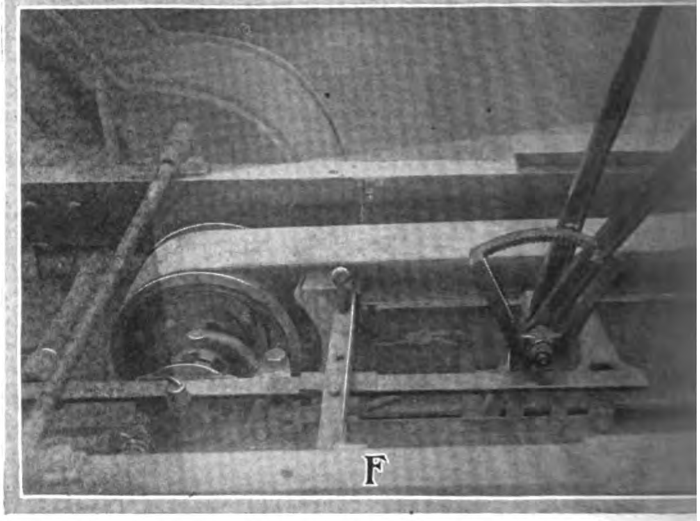
E—Racing type of Forster light car. Stripped chassis. Capable of 50 miles an hour.



F—Forster light car. Belt drive and two-speed gear. Final drive by single side chain

tion to all moving parts. As a matter of fact, there is less exposure to dust and moisture on this cheap little car than on many a $5,000 production. There are only two speeds, obtained by two dog clutches on the countershaft, the high gear giving a direct drive through from the motor to the locked countershaft, and the second clutch giving a suitable reduction. Ball bearings are used everywhere except in the motor; that is to say, on the four road wheels and in the countershaft, the only moving parts. There is no reverse, this not being required under the French law for a car weighing not more than 770 pounds; but in view of the added convenience the designer is about to fit one, to be worked off the same lever.

Speed is only a question of the motor and the most suitable gearing, the belt being able to take care of any power. On the standard model, with the 7-horsepower one-lunger, 30 miles an hour can be maintained on the level. With the two-cylinder Anzani and a change of the driving sprocket, the car can do well over 50 miles an hour on the level. For this fast work the bonnet is made lower than usual, the steering column is more inclined and longer, with a very large wheel, for there is no gearing between steering wheel and road wheels.

A 40-inch track leaves little room for two seats side by side, and with a view to comfort the designer of the car has placed the passenger's seat a little to the rear of that occupied by the driver; thus the elbows of the one do not interfere with the other. There is even a third folding seat in the rear, but as this is not intended to be regarded as such by the French fiscal authorities, it is folded away except when wanted for emergency passenger carrying. As a try-out of his car, the designer undertook a three weeks' trip through Algeria, which might be considered as the European equivalent of a coast-to-coast run. He came back convinced that he had got hold of the right idea for a light, speedy, and economical car.

Two models are produced, one with the steering wheel on the left and levers in the center, for countries where the rule of the road is the same as in America, and another one with the wheel on the right, for use under the English rule of the road.

Large Flywheel Used on Small Motors

It will be understood that flywheel effect is as necessary as the motor from a certain point of view. Not so long ago it was the choice of a certain class of designers to reduce weight of the flywheel to the greatest possible extent, and in six-cylinder motors it was claimed that almost no flywheel effect is necessary. Experience has shown that a large flywheel is efficacious as a power storage medium, and that it has a value over and above the mere matter of helping the motor to complete its cycle.

Valve Action and Other Influences for Efficiency

MANY autoists find that the cars they drive after they run for a time become mysteriously unruly, and, despite their earnest effort, fail to respond to the remedies applied. When a motor shows evidence of weakening, the autoist immediately arrives at the conclusion that his ignition system is out of order, because to him there is more mystery in an ignition system than in anything else, and his reasoning power becomes befogged by the weight of negative evidence thus afforded. If, in the course of investigation, the autoist is able to determine to his own satisfaction that the ignition system is in good working order, his attention next lights on the carbureter, and if after "tickling" the same to make it spew an excess of gasoline, the process does no good, it is in order to tamper with the adjustments long enough to make sure that the automobile will not run at all.

Strength of Valve Springs Must Be Watched

It would be more to the point to find out if the parts are all present, and if they are properly related to each other. A wobbling joint, or a nut lost off of a bolt head, or a dozen and one other mechanical derangements, including a plugged-up passage-way, might account for all the trouble, but there are other possibilities that are harder to find, hence the mystery in many cases.

Few indeed are the problems that have to be solved that are more troublesome to the operator of a car than the one involving the strength of the valve springs. If they are too strong, the cams and lifts will be damaged too soon, but if they are not strong enough, the timing will get out of order. It is not generally recognized that timing a motor is only a partial process, on account of the fact that the mechanism is only positive in one direction. True, the cam lifts the valve off of its seat at a set time, but the spring placed to close the valve is not positive. If the spring is "lazy" the angular rotation of the camshaft will be increased to excess before the valve will be pressed against the seat. On account of the structural changes that springs undergo it is impossible to so design them that they will be just right for the work to be done all the time, and it is the practice among makers to employ over-strong springs in new motors, with the expectation that they will never weaken to a point where they will fail to serve for the purpose.

The chances are that the pressure should be about 40 pounds per square inch between the valve and the seat, and that it will remain so at all times is highly improbable. If the spring is strong enough to withstand the work without mechanical or structural deterioration independent of the effect of heat, it only remains to so place the same that its temper will not be drawn by the heat. Unfortunately springs are required to work up to the limit of their fiber ability, and they are likely to undergo some change from this account. Then the heat is enough in many examples to anneal the metal so that some weakening is to be expected from this cause.

It would be good work were the springs placed to close valves capable of doing so within a rotation of 20 degrees of the camshaft. The angular travel of the camshaft is frequently more than 40 degrees. The method of calculating for this angle is given as follows:

Let,

θ — Angle of camshaft rotation during the closing of the valve under the action of the valve spring.

S — Speed of the camshaft in revolutions per minute.

W — Weight of valve in pounds.

P — Mean pressure of the spring in pounds.

1 — Lift of the valve in inches.

When,

$$\theta = \sqrt{\frac{.1\,(S\,W)^2\,W}{0.67\,P}}$$

While noise is the normal expectation if the spring does not work properly, it is believed that the most noise comes from weak springs rather than when the pressure is excessive. To withstand the pressure the parts, as the roller, pin, cam-face and ends of the rods, must be of close-grained metal and well hardened—this is not always the case.

Altitude Influences Radiator Action a Little

The factor of safety required in a radiator for an automobile must be subdivided (a) from the mechanical strength point of view, and (b) considering the capacity of the radiator to do the work required of it. The condition (a) is not easy to settle; experience will have to be the guide to a large extent. That the radiator should be flexibly mounted is one of the settled conditions. The question of capacity and the margin to allow against unusual demands, is capable of being disposed of to quite some extent. Altitude, for illustration, has its effect as follows:

BOILING POINT OF WATER AT VARIOUS ALTITUDES.

Feet Above Sea Level	Boiling Point in Deg. F.
Sea Level	212
1,025	210
2,063	208
3,115	206
4,169	204
5,225	202
6,304	200
7,381	198
8,431	196
9,579	194
10,685	192

Sediment and incrustation also have to be allowed for, and the chances are that radiators will depreciate in ability about 33 per cent. within a single year. This depreciation will probably reach a maximum within the stated time, excepting in the cases where lack of attention is at the bottom of the trouble. There is no way of determining what to allow for such cases. Radiators that do not "steam" will surely reach a stable level if the water used is reasonably free from foreign substances. So little water will have to be added in a year that all the sediment that can get into them will be very limited. Unfortunately, a very slight coating of sediment or scale will have a large effect, and 33 per cent is a fair allowance.

In filling a radiator it is wrong to supply so much water that there will be no free space; water swells when it is heated in a cooling system, owing in part to the increase in the temperature, but for the most part owing to the presence of steam.

New Two-Cycle Motor with Rotary Intake Valve

By W. F. BRADLEY

A prominent French engineer, Georges Deloche, is responsible for the design of the two-cycle motor here illustrated; it has four vertical cylinders with copper water jackets; ignition is by high tension magneto; the crankshaft has five bearings; exhaust ports are uncovered by the piston on the down stroke; the peculiarity of the motor is due to the use of rotary valves carried in the position usually occupied by the camshaft.

INTEREST in two-cycle motors, while it has been tame at times, persists, nevertheless, and the impetus which has been given rotary types of valves of late is having its influence upon the two-cycle motor quite as much as it modifies the ideas which are dominant in connection with four-cycle efforts. A two-cycle motor with a rotary intake valve has been placed on the market by the French engineer, Georges Deloche. In all but one feature the motor conforms to standard practice. It has four vertical cylinders of 3.9 inches bore and 5.5 inches stroke, with copper water jackets, pump circulation, ignition by high-tension magneto, a five-bearing crankshaft and exhaust through a port uncovered by the piston at the end of its downward course.

The peculiarity of the motor is that a rotary valve is carried in the position usually occupied by the camshaft on a four-stroke motor, and like this, is driven by spur gears from the main shaft. The rotary valve is a rather large-diameter hollow shaft, provided with six openings or ports. Two of these extend entirely round the circumference of the shaft, leaving just the necessary amount of metal required for strength, while the four others are of smaller dimensions. The two large openings communicate with the intake piping and at all times provide a free opening from the carbureter to the interior of the shaft. The four smaller openings each correspond with an intake port, admitting to the interior of the four separate crankcase divisions. On the upstroke of the piston the openings in the rotary valve correspond with the intake ports, allowing a charge to be drawn in through the hollow shaft and compressed within the crankcase against the closed valve, on the downward course of the piston. As in the majority of two-stroke motors, a by-pass is provided, by which the charge already compressed in the crankcase can be passed into the combustion chamber on the port being uncovered as the piston nears the end of its stroke.

The same principle applies to a two-cylinder model, the rotary valve in this case, however, having but three openings, one in constant communication with the carbureter, and the two others giving admission into the crankcase division at each revolution. On the single cylinder model the inventor makes the crankshaft fulfill the functions of rotary valve. The shaft is hollow, and is cut away for a portion of its circumference to give a free opening from the intake pipe; the charge passes through an intake port in the crankcase, to the interior of the case, where compression takes place on the downward stroke of the piston.

In the illustrations on the opposite page, A shows the Deloche 4-cylinder, 2-cycle motor, with intake ports and rotary valve; B, the same, with cylinder dismounted and rotary valve partially withdrawn; C, rotary valve; D, 2-cylinder, 2-cycle motor of same make; E, 4-cylinder, 2-cycle motor, exhaust side; F, cylinder and piston of same; G, crankshaft; H, connecting rod; I, side elevation of the 2-cycle motor.

There is no doubt about the desire on the part of French designers to travel in the direction of simplicity, and the great aim beyond the matter of ease of repair lies in the high cost of fuel. Small motors, then, are looked upon with a longing eye, and they favor the two-cycle plan.

Foreign Armies Quitting the Horse

By W. F. BRADLEY

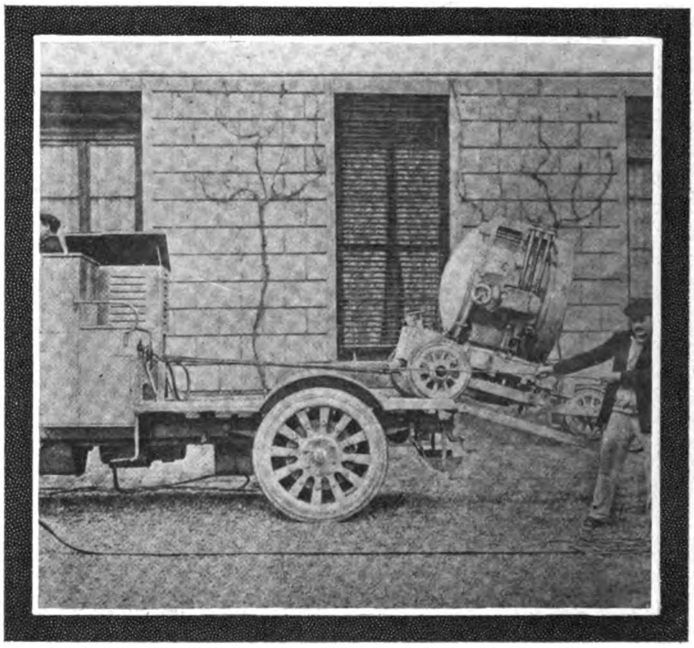
Horse-drawn vehicles being abandoned for searchlight equipment transportation; generating plant consists of dynamo and a gasoline motor to drive it; searchlight comprises another unit; chassis rolls on solid rubber tires; pneumatic control of the searchlight eliminates some troubles; projectors may be removed to ground in some models; methods for convenience and quick action shown.

ARMY organizations in Europe are keyed up to the highest pitch all the time, and the earnestness with which the automobile is taken advantage of there is a matter which may well be looked into in this country, not only on account of the advantages offered in the way of better military efficiency, but in view of the attraction which a new field has for the makers of automobiles.

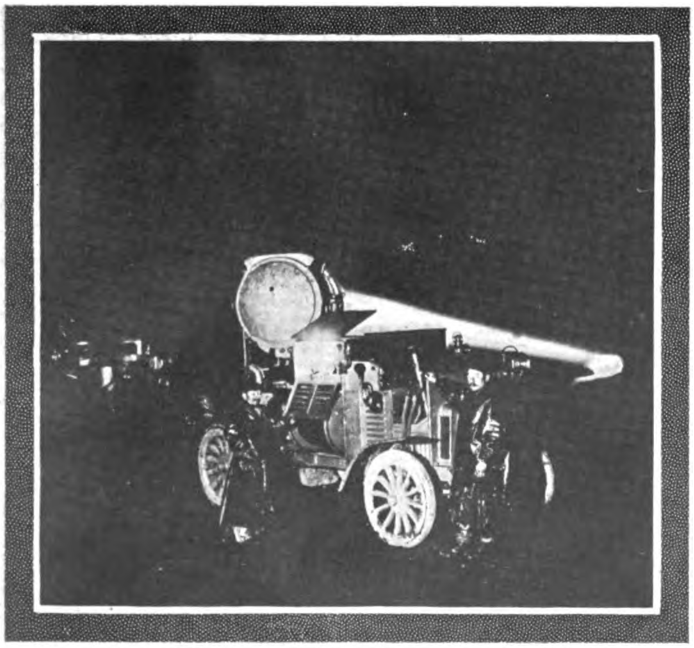
The horse has had to give way to the motor in another branch of army work. Up to the present, portable searchlights have been carried on horse-drawn vehicles, the generating plant, consisting of a gasoline motor and dynamo forming one unit, and the searchlight forming another and independent outfit. Each unit was carried on a separate vehicle. To be put into service the two units had to be connected, obviously, with a certain loss of time; and they could never send an investigating flash of light across the country when the vehicle was in movement on the highway. Even with six horses for each vehicle the outfit was not moved with all the rapidity that could be desired.

In future French troops will use a motor-driven searchlight, of a model produced by the De Dion Bouton Company and the Breguet concern, and officially adopted after searching tests by the staff officers. There is now no possibility of a failure owing to one of the vehicles getting astray, for the electricity producing plant and the projector form one unit and are self-propelled. The automobile portion of the apparatus consists of an 18-horsepower De Dion chassis suitably strengthened for the work it will have to perform, and fitted with a four-cylinder motor carried under the driver's feet. The chassis is mounted on single solid rubber tires in front and twin solids in the rear. The gear set gives three speeds forward and reverse, with a maximum of 20 miles an hour under full load on a level highroad, and an ability to climb grades of 15 per cent. Gasoline consumption works out at the rate of 10 miles to the gallon. Drive is taken through plate clutch, three-speed gear box and transverse cardans to the road wheels. Besides the rear wheels the motor also drives the dynamo mounted on the main shaft, either with the vehicle in motion or in a stationary condition. The entire electric outfit is arranged immediately to the rear of the driver's seat, the electrician sitting with his back to the driver, and in this position having in hand the entire control of the searchlight.

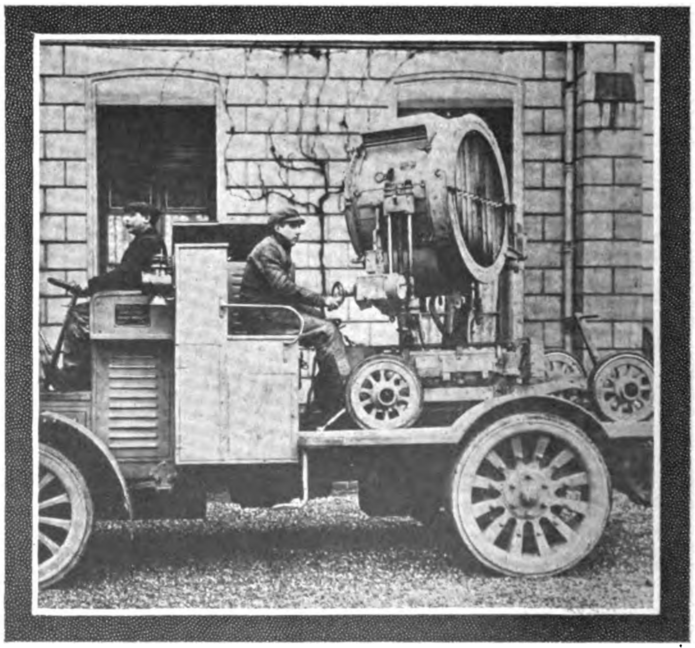
Three-quarters of the body area to the rear of the driver is left free to receive the searchlight, a Breguet instrument, the reflector of which has a diameter of 36 inches and flashes a light equal to 7,000 Carcel lamps. The projector is carried on two spring-supported forks attached to a circular track, thus allow-



Lowering the searchlight from automobile truck



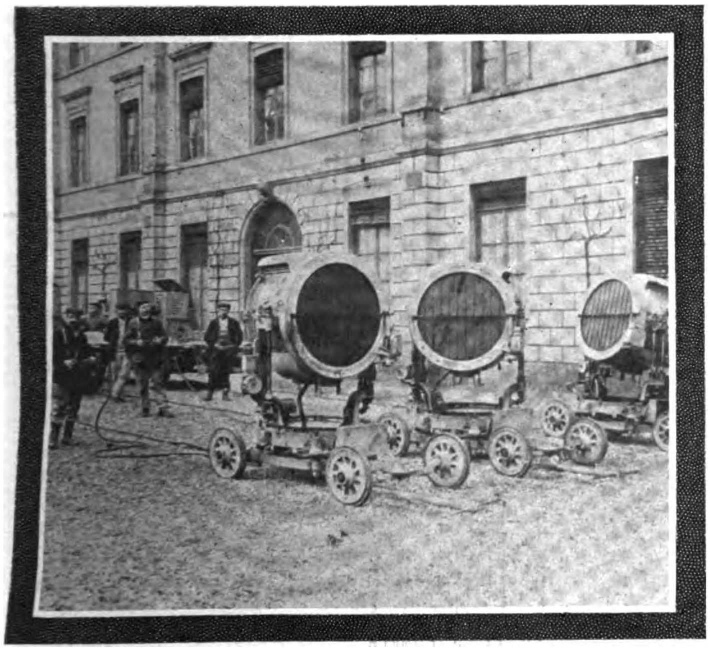
French army automobile searchlight in action



Projector raised in position for operating on the road ing for free movement in every direction. The carriage is mounted on a four-wheeled bogie, the front wheels of which are pivotable and the whole specially designed to be received on the platform of the truck. When not in use the projector is lowered until it is well within the carriage, thus keeping the center of gravity low. If the projector is to be used on the road, it can be quickly raised by hand and the glare of the lamp flashed on any object even with the vehicle in motion.

When the automobile has been brought to a stop, the 18-horsepower motor is used exclusively for driving the dynamo. The apparatus may be operated either from the platform of the truck or with the projector taken down to the ground. The operation is a simple one, requiring the services of two men only; by means of an inclined platform attached to the rear of the truck, the bogie is run down to the ground under the control of a hand-operated winch. The electric cable supporting the current is wound on a drum, and on the projector being brought to the ground is automatically unwound for a maximum length of 100 yards, thus allowing the searchlight to be maneuvered into the most favorable position for operating while the motor continues to drive the dynamo only.

As the operation of a powerful searchlight at close quarters is very trying for the eyes, the instrument has been provided with a system of pneumatic control allowing the projector to be turned in any direction or placed at any angle while the operator is 15 to 20 yards in the rear. When the operator is working the searchlight from the motor vehicle the control is direct and by hand.



Projectors in position for operation. Compressed air control

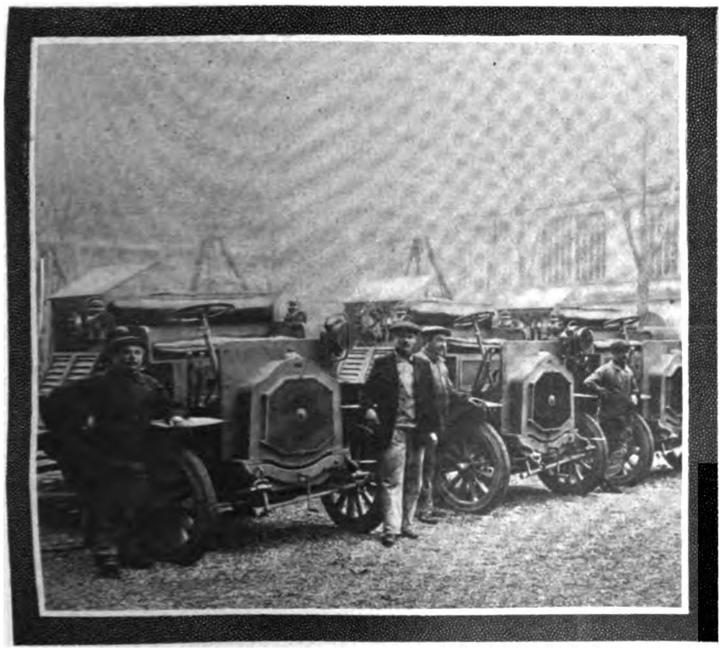
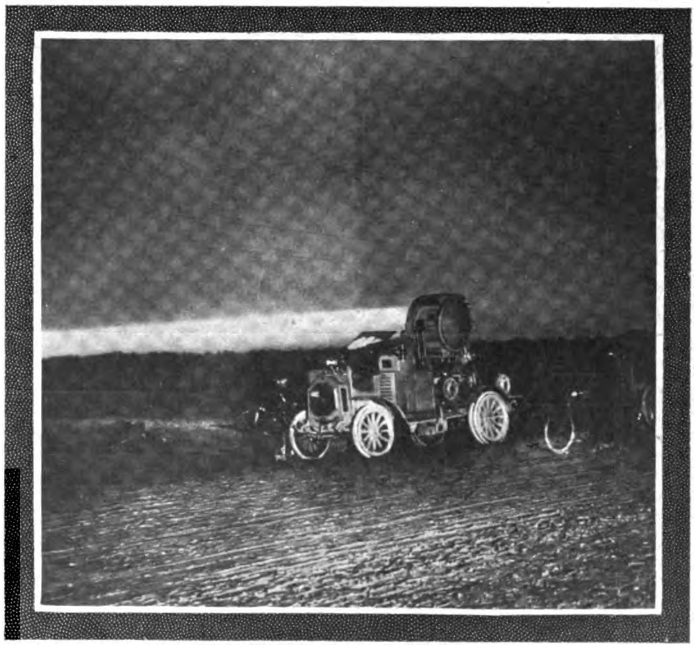
Producer-Gas Offers Certain Promise

In a certain class of freighting work involving the use of tractors and a train of cars, it is just possible that producer-gas will take the place of gasoline. The average gas of this character from anthracite coal has a thermal value of about 135 British thermal units of heat, and the various constituents by volume are:

Carbon dioxide, CO_2, 6 per cent. Carbon monoxide, CO, 24 per cent. Hydrogen, H, 15 per cent. Nitrogen, N, 55 per cent. Hydrocarbon, CH_4, trace. Oxygen, O, trace. Producers may be made in quite compact form and the fuel required per hundred miles of travel is not so much that it would more than serve as ballast for the tractor.



Army automobile searchlight trucks



Night photograph of French army automobile searchlight in action

$$\frac{210.15-27.29}{226} = 0.808,$$

Whence $n = 0.368 \times 0.808 = 0.296$. The entropies of vaporization are

$$\frac{305.04}{305 + 460} = 0.400, \text{ at 150 pounds pressure,}$$

$$\text{and } \frac{432.97}{79 + 460} = 0.808 \text{ at 1.27 pounds pressure.}$$

In an ideal vapor cycle using a vapor intially dry, the dryness at the end of expansion is computed by a familiar formula of thermodynamics,

$$n_2 - n_1 + N_2 = xN_1,$$

in which the symbols n refer to liquid entropies, N to entropies of vaporization, and the subscripts 1 and 2 to the lower and upper pressure limits respectively. We have, then, for alcohol,

$$0.296 + 0.400 = 0.808\, x$$

whence $x = 0.862$: and for steam

$$0.5142 - 0.1471 + 1.0550 = 1.8082\, x$$

whence $x = 0.79$.

The efficiency of this ideal cycle is expressed by the formula,

$$(h_2 - h_1 + L_2 - xL_1) \div (h_2 - h_1 + L_2),$$

in which the symbols h stand for heats of liquids, and L for latent heat of vaporization; the subscripts having the same significance as before. This leads to

$$\text{Ideal efficiency with steam} = \frac{330.2 - 77.94 + 863.2 - (0.79 \times 1030)}{330.2 - 77.94 + 863.2} = 0.271,$$

and with alcohol =

$$\frac{210.15 - 27.29 + 305.04 - (0.862 \times 432.97)}{210.15 - 27.29 + 305.04} = 0.235$$

The comparison is distinctly unfavorable to alcohol, and the reason is not far to seek. Ideal efficiency is increased as the temperature range is increased. In establishing the same pressure limits for both steam and alcohol, we have necessarily fixed the temperature range at 79 degrees Fahrenheit to 305 degrees Fahrenheit for the latter and 110 degrees Fahrenheit to 358 degrees Fahrenheit for the latter. The steam works through 248.5 degrees Fahrenheit and the alcohol through 226 degrees Fahrenheit.

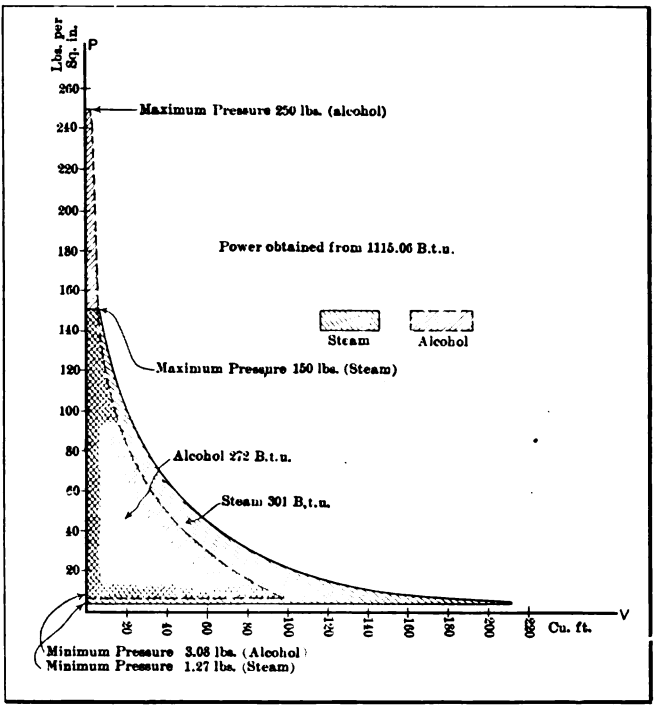


Fig. 4—Power diagram drawn to show the pressure per square inch under different conditions involving alcohol and steam

The Choice of a Fluid

While alcohol, ether, sulphur dioxide or gasoline have the advantage arising from a low boiling point in decreasing the lower temperature limit without making excessive demands upon the vacuum pump, that very fact leads to the disadvantage of a high pressure at the upper limit of temperature: which can be escaped only when the variation of pressure with temperature is much less rapid than is the case with steam. The following table shows how various substances compare in this respect:

Temp., deg. F.	Corresponding pressure at the boiling point, lbs. per sq. in.						
	Ethyl Alcohol	Gasoline	Ether	Acetone	Chloroform	Carbon Bisulphide	Steam
113	3.35	8.20	21.0	10.0	8.79	14.3	1.38
248	62.9	54.6	150.	88.5	76.5	100.3	28.8

All of these substances permit of a lower exhaust temperature than can be obtained with steam, either condensing or non-condensing; but all of them also give at even as moderate a temperature as 248 degrees Fahrenheit, a pressure considerably in excess of that necessary in the steam engine. The question of mechanical design for higher pressures has already become sufficiently troublesome to limit the development of the steam engine in that direction. A slight gain in thermal efficiency at a cost of a serious jump in pressure would not be worth considering. The only substitute for steam seems to be in the direction of the binary vapor engine, in which the binary fluid will never be worked at high pressure.

Removal of Upper Pressure Limit

While the comparison is not fair, and has little practical bearing, it is interesting to note what results follow the adoption of 358.5 degrees Fahrenheit as the upper temperature limit in the case of the alcohol engine just considered. (It is to be noted that the lower temperature limit remains unchanged.) The latent heat of vaporization at 358.5 degrees Fahrenheit is 276; the heat of the liquid is 264; the pressure approaches 250 pounds per square inch. (We have extrapolated values only for the thermal properties at this temperature.) The difference of liquid entropy between 79 degrees and 358.5 degrees is, very nearly,

$$\frac{264 - 27.29}{358.5 - 79} \log \epsilon \frac{358.5 + 460}{79 + 460} = \frac{236.71}{279.5} \log \epsilon \frac{818.5}{539}$$

$$= 0.849 \times 2.3 \log 1.52 = 0.356.$$

The entropy of vaporization at 358.5 degrees Fahrenheit is

$$\frac{276}{358.5 + 460} = 0.338.$$

The dryness at the end of adiabatic expansion comes from

$$0.356 + 0.338 = 0.808\, x \text{ as } x = 0.694 \div 0.808 = 0.86$$

The efficiency of the alcohol vapor cycle between 358.5 degrees Fahrenheit and 79 degrees Fahrenheit is then

$$\frac{264 - 27.29 + 276 - (0.86 \times 432.97)}{264 - 27.29 + 270} = \frac{512.71 - 372}{512.71} = 0.274,$$

slightly greater than that of the steam cycle with the same upper temperature limit and same lower pressure limit; but the alcohol engine must stand 250 pounds pressure and the steam engine only 150 pounds. Considering the temperature limits as fixing the ideal efficiency, the steam cycle is the better of the two, for it gives practically the same efficiency, although working with a temperature range 31 degrees or 11 per cent. less.

Identical Temperature Limits

Suppose we compare steam and alcohol, both working between 358.5 degrees Fahrenheit and 110 degrees Fahrenheit. The potential efficiency is the same in both cases,

$$\frac{358.5 - 110}{358.5 + 460} = 0.304$$

For alcohol, at 110 degrees Fahrenheit, the pressure is 3.14

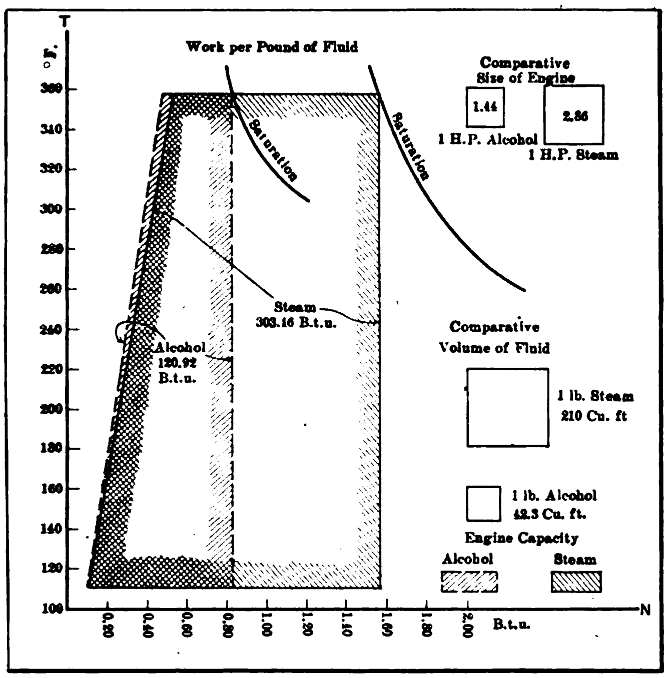

Fig. 5—A construction used in making a comparison between alcohol and steam, giving the relative sizes of engines

pounds, the heat of the liquid is 46.58, and the heat of vaporization is 426.22. The difference in liquid entropy between 110 degrees and 358.5 degrees Fahrenheit is

$$\frac{264-46.58}{358.5-110}=\frac{358.5+460}{110+460}\log_{\epsilon}=\frac{217.42}{248.5}\log_{\epsilon}\frac{818.5}{570}=$$

$$0.878 \times 2.3\ \log\ 1.437=0.32$$

The dryness at the end of adiabatic expansion is

$$(0.32+0.338)\div\frac{426.22}{110+460}=0.876,$$

and the efficiency of the alcohol cycle is

$$\frac{264-46.58+276-(0.876\times 426.22)}{264-46.58+276}=0.245,$$

against 0.271, as already found for the steam cycle.

Additional Considerations

In the comparison last made, the work obtained from one pound of fluid is given by the numerator of the efficiency expression: For alcohol, it is 120.92 B.t.u., and for steam, 303.46 B.t.u. The engine cylinder must be sufficiently large to hold one pound of fluid at the lowest pressure attained in the cycle in order that these amounts of power may be exerted by the one pound in each case. The volumes are obtained (approximately) by multiplying the volume of one pound of dry vapor at the lowest pressure by its dryness after adiabatic expansion. This gives, for steam, $265.5 \times 0.79 = 210$, and for alcohol, $48.238 \times 0.876 = 42.3$; the first figures of each product being tabular specific volumes. The ratio of

$$\frac{\text{work per pound of fluid}}{\text{volume of cylinder per pound of fluid}}$$

is then, for steam, 1.44, and for alcohol 2.86. An engine of given size, operated with alcohol, will then develop about twice the amount of power that will be developed when steam is used as a fluid. An extension of this calculation will show that the higher pressure necessary in a practical alcohol engine might be partially offset, so far as its influence on first cost is concerned, by the smaller size of cylinder necessary.

Again, the amount of heat to be abstracted by condensing water is given by the last term of the numerators of the efficiency expressions. For steam, this is $0.79 \times 1030 = 813$; for alcohol, it is $0.876 \times 426.22 = 375$. The ratios of these quantities to power developed are,

$$\text{for steam, } 813 \div 303.46 = 2.69;$$
$$\text{and for alcohol, } 375 \div 120.92 = 3.10.$$

The alcohol will require more cooling water per horsepower in the ratio of 3.10 to 2.69; say 15 per cent. more; and the necessary size of condenser will be correspondingly increased.

Conclusions

Some of the results of these computations are shown graphicacally in Figs. 4, 5 and 6. In the first, we have the ideal indicator diagrams obtained from alcohol and steam working betweeen 358.5 degrees Fahrenheit and 110 degrees Fahrenheit. The maximum pressures are shown as 250 and 150 lbs., and the minimum as 3.08 and 1.27 lbs., respectively. Our computations gave a work area of 301 B.t.u. with steam when the total heat supplied was 1115.06 B.t.u. Reducing the work obtained from alcohol to the same basis of heat supplied, we obtain 272 B.t.u. The two shaded areas of Fig. 4 then represent the relative efficiencies of the two fluids with identical temperature limits.

Fig. 5 shows the entropy diagrams for the two ideal cycles. Here the work areas obtained *per pound* of fluid are given as 120.92 and 303.46 B.t.u. The difference in specific volumes at the lower temperature limit (indicated by the two squares in the lower righthand corner of the diagram) leads, however, to a greater output from a given cylinder when supplied with alcohol than when supplied with steam; or, as represented by the squares in the upper righthand corner of the diagram, the steam engine of a given horsepower is twice as large as the alcohol engine.

Fig. 6, again, shows the heat to be removed by the cooling water per pound of fluid; b j e a for alcohol, b i h a for steam. The lesser amount of work obtained from a pound of alcohol, however, offsets this and leads to the result shown; the condenser for alcohol must be 15 per cent. larger, and the amount of cooling water supplied must be 15 per cent greater, than with steam.

Thermal efficiency is limited (a) by the mechanical difficulties accompanying high initial pressures or temperatures, and (b) by the difficulty of attaining a low temperature limit, on account of the normally available 60 degrees or 70 degrees Fahrenheit temperature of cooling water and the mechanical difficulties in maintaining a vacuum even at this temperature. Steam is as satisfactory a vapor as any, if we consider condition (a). It is almost the least satisfactory of any under condition (b), but the gain in eliminating high vacua at the lower limit is so small that the thermal properties of any specific vapor may be such as to offset it. The cooling water temperature imposes an insurmountable barrier to progress in respect to this lower limit. With a properly chosen fluid the binary vapor principle may lead to the highest thermal efficiencies, but these are not likely to be commercially profitable on any wide scale. Specimen comparisons show alcohol to be rather less efficient than steam as a working fluid: we have insufficient data to consider gasoline. The reason for using these substances arises from convenience, quick steaming, etc., and the alcohol engine may be smaller than a steam engine of same power.

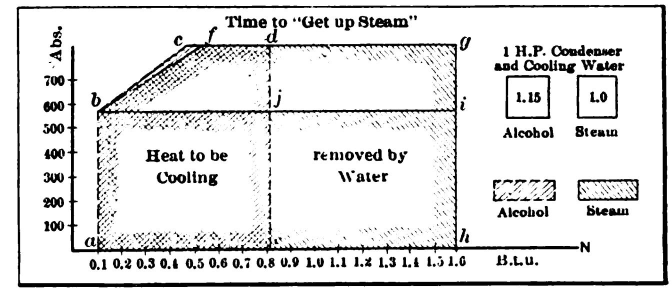

Fig. 6—Time of starting, cooling water and condenser

(The comparative times required to "get up steam" are indicated by the areas a b c d e—alcohol,—and a b f g h—steam. This is for equal weights of fluid in the boilers. These areas have the ratio 4:10. The amounts of heat to be removed by the condenser cooling water per pound of fluid are represented by the areas b j e a—alcohol,—and b i h a—steam; the ration being 4.6:10. Since more work is obtained per pound of fluid in the case of steam—see Fig. 5—the cooling water supply and size of condenser per horsepower are, however, reduced below those necessary for alcohol.)

Standardized Formulæ for Ready Reference

By THOS. J. FAY

Dealing with simplified conversion formulæ set for the slide rule, or to be used independent of same, logically arranged, and indexed by number—Empirical formulæ for determining horsepower approximations (a) for steam engines, and (b) for internal combustion motors—Practical electrical formulæ derived from the fundamental system for use in ignition work—Practical electromagnetic formulæ derived from the fundamental system for use in designing ignition systems—Abbreviated adaptations of general engineering formulæ for quick approximations

AUTOMOBILE ENGINEERS have to deal with many old problems in new garb, and the fixed formula which obtains for bridge building, electrical engineering, and battleship designing, while it holds the crux of the situation from these points of view, lacks in fineness in view of the more delicate task which confronts the designer of the automobile. Empirical formulæ in particular are dangerous to apply to the newer art, using the constants which were found to serve under the well-defined conditions which were established for the older arts. Even with a derived formula having for its basis the fundamental system, there is a certain amount of danger involved, and before it can be claimed that the automobile is standardized, it will be necessary to standardize the formula which is to serve as the method of precision for the designer.

In the shop when a part is fashioned it goes to the inspection department, where a deft inspector, imbued with high ideas, utilizes micrometers, extensometers, and fixed gauges to enable him to fix the standard the workman observes. To arrive at such close conclusions in the shop, it goes without saying that they should be based upon a mathematical design which will serve as an exact foundation for results so obtained. If the designer uses a formula which leads to wrong conclusions, what an enormous waste of talent and money it is to use $5,000 worth of instruments of precision in the process of proving how nearly the artisan comes to making the thing wrong! If the mathematical hypothesis is wrong, then the part involved, if it is made according to the formula, will be wrong, and every effort to arrive at accuracy of workmanship, under such conditions, will be for no better purpose than to show that the workman furnished a Chinese copy of a wrong design.

The method of comparison, which undoubtedly obtains to a wide extent, when reference is had to automobile designing, cannot represent the last word because no one can be held responsible for the accuracy of the parts which are used in the copying process. Even if an axle does hold up in some one make of automobile, and even if it is extensively copied, these facts do not constitute proper groundwork for a standardized product. If the original and possibly well-designed axle falls short of the perfection which would be indicated by proper investigation and the utilization of sound mathematical formulæ tempered by practical considerations, every effort based upon it will be below the standard which a board of capable engineers would be proud to embrace as their own.

The time must come in the automobile industry when the methods which are relied upon in the engineering office will be universal in character and bear the stamp of approval of a board of competent engineers empowered to act. In every other art, heterogeny of designing method was ultimately set aside in favor of crystallized endeavor due to systematic investigation, as, for illustration, the master car builders' specifications (M. C. B.) are the rule and guide in every effort involving the building of cars, the tracks on which they roll, and the locomotives that draw them. Likewise, in shipbuilding the Lloyds construction is recognized by insurance underwriters as the standard to measure by, just as in medicine the United States Pharmacopœia states the dosage which the sick must endure.

$$\text{Litres per Second} = \frac{53 \times \text{U. S. Gallons per Minute}}{840} \tag{121}$$

Practical Electrical Formulæ Fundamentally Derived

$$R = \frac{E}{I} = \text{Resistance in Ohms} \tag{122}$$

$$R = \frac{W}{I^2} = \text{Resistance in Ohms} \tag{123}$$

$$R = \frac{E^2}{W} = \text{Resistance in Ohms} \tag{124}$$

$$I = \frac{E}{R} = \text{Current in Amperes} \tag{125}$$

$$I = \frac{W}{E} = \text{Current in Amperes} \tag{126}$$

$$I = \sqrt{\frac{W}{R}} = \text{Current in Amperes} \tag{127}$$

$$E = IR = \text{Electromotive Force in Volts} \tag{128}$$

$$E = \frac{W}{I} = \text{Electromotive Force in Volts} \tag{129}$$

$$E = \sqrt{WR} = \text{Electromotive Force in Volts} \tag{130}$$

$$W = EI = \text{Energy in Watts} \tag{131}$$

$$W = I^2R = \text{Energy in Watts} \tag{132}$$

$$W = \frac{E^2}{R} = \text{Energy in Watts} \tag{133}$$

$$J = \frac{E^2}{R}t = \text{Heat in Joules} \tag{134}$$

$$J = I^2Rt = \text{Heat in Joules} \tag{135}$$

$$J = EIt = \text{Heat in Joules} \tag{136}$$

$$Q = \frac{E}{R}t = \text{Quantity in Columbs} \tag{137}$$

$$Q = It = \text{Quantity in Coulombs} \tag{138}$$

$$C = \frac{Q}{E} = \text{Capacity in Farads} \tag{139}$$

$$C = \frac{(It)}{E} = \text{Capacity in Farads} \tag{140}$$

$$C = \frac{\left\{\frac{E}{R}t\right\}}{E} = \text{Capacity in Farads} \tag{141}$$

Note:—In the construction of condensers for use in magnetos and spark coils in connection with ignition systems for automobile motors, a more practical determination of condenser capacity is expressed as follows:

Let,
C = Capacity in farads;
Cl = Capacity in micro-farads;
k = A constant representing the specific inductive capacity of the dielectric;
A = Area of conductor plates in square centimeters;
d = Distance between plates (thickness of dielectric) in millimeters;

When,

$$C = \frac{kA}{4\pi d} = \text{Capacity in Farads} \tag{142}$$

$$Cl = \frac{k\,A}{1.1313 \times d \times 10^7} = \text{Capacity in Micro-Farads} \tag{143}$$

$$A = \frac{1.1313 \times k \times d \times 10^7}{k} = \text{Area in Sq. Centimeters} \tag{144}$$

Note:—The specific inductive capacity of air equals unity; the specific inductive capacity of other media is variable, but authorities give some of the values as follows:

Paraffine = 2.16
Oiled paper = 2.00
Mica = 4.75
Ebonite = 2.67
Petroleum = 2.05
Ozokerite = 2.10

Relation of Horsepower to Electromagnetic Units

Since 1 watt equals 1-746 of a horsepower, the relations as follows hold:

$$\text{H.P.} = \frac{W}{746} = \text{Horsepower} \tag{145}$$

$$\text{H.P.} = \frac{EI}{746} = \text{Horsepower} \tag{146}$$

$$\text{H.P.} = \frac{I^2R}{746} = \text{Horsepower} \tag{147}$$

$$\text{H.P.} = \frac{\left\{\frac{E^2}{R}\right\}}{746} = \text{Horsepower} \tag{148}$$

$$\text{H.P.} = \frac{\text{KW} \times 1{,}000}{746} = \text{Horsepower} \tag{149}$$

$$\text{K.W.} = \frac{\text{H.P.} \times 746}{1{,}000} = \text{Kilowatts} \tag{150}$$

Heat Equivalent of Electrical Energy

$$H = I^2Rt \times 0.24 = \text{Calories} \tag{151}$$

$$t = \frac{H}{I^2R} \times 0.24 = \text{Time in Seconds} \tag{152}$$

Conventional Formulæ of the Steam Engine

$$\text{I.H.P.} = \frac{Ps \times A \times Mp}{33{,}000} = \text{Indicated horsepower} \tag{153}$$

$$Mp = \frac{\text{I.H.P.} \times 33{,}000}{A \times Ps} = \text{Mean effective pressure} \tag{154}$$

$$A = \frac{\text{I.H.P.} \times 33{,}000}{Mp \times Ps} = \text{Area in Square Inches} \tag*{155}$$

$$Ps = \frac{\text{I.H.P.} \times 33{,}000}{A \times Mp} = \text{Piston Travel in Feet Per Minute.} \tag{156}$$

The mean effective pressure to be expected from a properly constructed and suitably adjusted steam engine may be approximated as follows:

$$Mp \text{ (1-4 cut-off)} = \frac{Ip \times 34}{57} = \text{Mean effective pressure} \tag{157}$$

$$Mp \text{ (3-8 cut-off)} = \frac{Ip \times 23}{31} = \text{Mean effective pressure} \tag{158}$$

$$Mp \text{ (1-2 cut-off)} = \frac{Ip \times 11}{13} = \text{Mean effective pressure} \tag{159}$$

$$Mp \text{ (5-8 cut-off)} = \frac{Ip \times 34}{37} = \text{Mean effective pressure} \tag{160}$$

$$Mp \text{ (3-4 cut-off)} = \frac{Ip \times 53}{55} = \text{Mean effective pressure} \tag{161}$$

$$Mp \text{ (7-8 cut-off)} = \frac{Ip \times 124}{125} = \text{Mean effective pressure} \tag{162}$$

For a single-acting steam engine working 1-4 cut-off, if it is in good working order and the valves are tight, the horsepower to be realized should be as follows:

$$\text{I.H.P.} = \frac{\left(d^2 \frac{\pi}{4}\right) \times \left(\frac{Ip \times 34}{57}\right) \times \left(\frac{S \times 2}{12} \times R\right)}{33{,}000} = \text{indicated hp.} \tag{163}$$

When,
Ip = Initial steam pressure:
S = Stroke in inches:
R = Crankshaft speed in revolutions per minute:
d^2 = Square of diameter of piston in inches.

Simple Rating Formulæ for Automobile Motors

The Association of Licensed Automobile Manufacturers, in an attempt to "rate" motors, reached the conclusion that there is no formulæ that will give absolutely accurate results, and, in the absence of a formulæ that can be relied upon to do more, preferred to lay down one that all may use on a nominal basis, taking for a foundation the conventional motors of the day, and a piston travel of 1,000 feet per minute as permissible. This formulæ is stated as follows:

$$\text{H.P.} = \frac{d^2n}{2.5} = \text{horsepower} \tag{164}$$

When,
d^2 = square of diameter of cylinder in inches;
n = number of cylinders on a 4-cycle basis.

It is believed that the time has arrived in the automobile motor when users would prefer to introduce a little complication if only they may be able to see for themselves the effect of a stroke. This may be accomplished in the manner as follows:

$$\text{H.P.} = \left\{\frac{m^2 \times m^1 \times n \times s}{10^9}\right\}k = \text{horsepower} \tag{165}$$

When,
m^2 = square of bore in millimeters;
m^1 = stroke in millimeters;
n = number of 4-cycle cylinders;
s = speed of crankshaft in revolutions per minute;
k = a constant for a given type and design of motor;
k = 4 for the conventional type of automobile motor;
10^9 = 1,000,000,000.

Note.—In dividing by 10^9 it is only necessary to point off to 9 decimal places. This formula, like that of the A.L.A.M., is purely empirical. hence is limited in its application to present types of 4-cycle motors. It closely approximates the power as realized from reasonably well-designed motors.

Relations of Torque, Speed and Power

It is frequently desirable to determine the relations of torque, speed and power; they may be ascertained as follows:

$$H.P. = \frac{2\pi RSP}{33{,}000} = \text{horsepower} \quad \ldots\ldots (166)$$

$$R = \frac{H.P. \times 33{,}000}{2\pi SP} = \text{radius of the lever-arm} \quad \ldots\ldots (167)$$

$$S = \frac{H.P. \times 33{,}000}{2\pi RP} = \text{speed in revolutions per minute} \quad \ldots\ldots (168)$$

$$P = \frac{H.P. \times 33{,}000}{2\pi RS} = \text{pull in pounds at end of lever-arm} \quad \ldots ((169)$$

With a Prony brake, using the above equation, if the length of the lever-arm is 5.4 feet, the horsepower becomes:

$$H.P. = \frac{6.28 \times SP}{1{,}000} = \text{horsepower} \quad \ldots\ldots (170)$$

Loads on Ball Bearings in Gear Transmissions*

ASIDE from the advantages of small friction, as compared with cylindrical bearings, and relative independence of lubrication, ball bearings offer undisputed points of superiority for automobiles in their ability to absorb end thrusts. A certain percentage of the radial load may be transformed into end thrust without harm. If a shaft has been designed too weak and bends under overload or shock, so that the inner race goes askew, the lateral stresses are without much trouble taken up by the balls, while with parallel bearings heating and scoring of shaft or bearing, with their evil consequences, are always to be feared.

But the stability of the shaft needs to be well looked after if two ball bearings close to one another are depended upon for the support of the load, as otherwise a bending of the shaft causes one of the bearings to be overloaded. The admissible loads for single ball bearings are given in the tables covering this subject and should not be exceeded. The loads on the gear pinion shafts in a transmission mechanism change greatly, however, according to the gear speed, and reach their maximum at low speed and reverse. At the other speeds the load on the ball bearing is considerably reduced. If, therefore, the dimensions of the ball bearing are decided according to the stresses obtaining at low speed or on the reverse, there will be a large unutilized surplus strength for the other gear ratios. Investigation of the transmissions used in a number of well-known automobiles shows, on the other hand, that the ball bearings in many cases are considerably overloaded. But temporary overloading of the materials is nothing new in automobile construction, and is also well endured within reasonable limits, owing to the excellence of the special automobile steels. Considering that the low speed and the reverse are switched into use only off and on and then only for a brief period, a small overload for the bearings at these speeds should be admissible with a view to a better utilization of ball bearings in normal operation, but in many instances in practice the overload is too great.

Roller bearings have been placed on the market which agree in dimensions with the established ball bearings and may be substituted for them, while capable of supporting loads 100 to 150 per cent. higher.

In the following there is offered an examination of ball bearing loads at the different gear speeds in a number of automobiles, with disregard of friction losses. The tables will show the actual loads and also the loads which are given as admissible by the manufacturers of ball bearings for the corresponding number of revolutions in each instance. The formula employed for the calculation of the turning moment is:

$$N = 0.4 \times 1 \times d^2 \times s \times 1200$$

but at the present advanced stage of motor design the coefficient 0.4 should be raised to 0.5 or 0.6, which will give 25 to 50 per cent. higher loads for given dimensions than are indicated in the tables, and an examination of the latter will disclose that, when this additional load due to the increased power of motors (as compared with their power at the time when the formula was calculated) is also considered, several transmissions show an overload even for the second speed. At the close of each table the percentage of overload, if any, is given. The data are compiled from published specifications.

An example of the calculations, with application of the above-mentioned formula, is given in full in the case of the Lorraine-Dietrich 20-horsepower transmission, used with a motor of 90 mm cylinder bore and 120 mm stroke.

The number of teeth on the various pinions is as follows:

Pinion A—26 teeth } giving a constant transmission ratio of 1 to 1.42
Pinion B—37 teeth }
Pinion C—15 teeth
Pinion D—41 teeth
Pinion E—23 teeth
Pinion F—33 teeth
Pinion G—29 teeth
Pinion H—27 teeth

Pinion J—17 teeth } reverse
Pinion K—12 teeth }

Multiplying with the constant gear speed ratio of 1 to 1.42, the total ratios for each gear speed are found to be 1 to 3.86 for low speed, 1 to 2.04 for second speed, 1 to 1.32 for third speed, 1 to 1 for fourth speed and 1 to 5.5 for the reverse.

The turning moment for shaft I is now seen to be 11 kilogrammeters and for shaft II 15.6 kilogrammeters. For shaft III the low speed gives a turning moment of 42.5 kilogrammeters; the second speed 22.4 kilogrammeters; the third 14.5 kilogrammeters; the fourth 11 kilogrammeters, and the reverse 60 kilogrammeters.

The stress on the teeth of the pinions A and B becomes 11,000 divided by 52, which equals 212 kilograms; for C and D, 15,600 divided by 33.75, which is 462 kilograms; for E and F, 15,600 divided by 51.75, or 302 kilograms; for G and H, 15,600 divided by 65.25, or 240 kilograms, and for the pinion-pair, K and J, the pressure rises to 7624 divided by 12, or 652 kilograms.

Looking at the diagram of the transmission, it will be noticed that the distances from the points where the shafts sustain their loads to the ball bearings are given in millimeters. Figuring with these distances in each case, the stresses upon the bearings are found to be as follows:

a_1 = stress on bearing a at low speed =

$$\frac{212 \times 35}{68} - \frac{126 \times 12}{68} = 109 - 22 = 87 \text{ kg.}$$

a_2 = stress on bearing a at second speed =

$$\frac{212 \times 35}{68} - \frac{178 \times 12}{68} = 109 - 31 = 78 \text{ kg.}$$

a_3 = stress on bearing a at third speed =

$$\frac{212 \times 35}{68} - \frac{167 \times 12}{68} = 109 - 29 = 80 \text{ kg.}$$

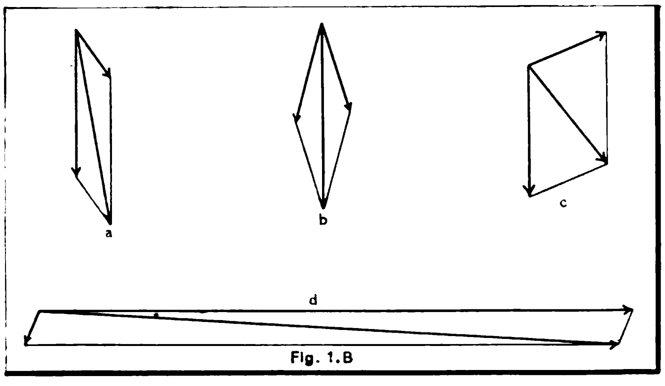

Fig. 1B—Showing parallelograms of forces which come into play when reverse is applied at various speeds

---

* Translation of article in *Der Motorwagen* by J. Dornacher.

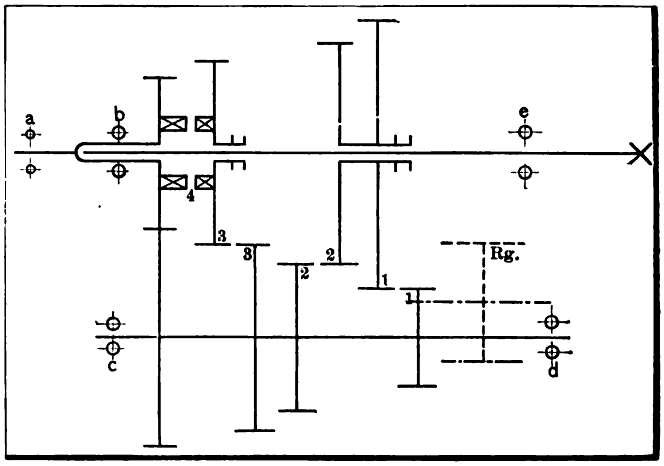

Fig. 4—Diagram of the transmission of the Peugeot "70"

The parallelograms of the forces which come into play when the reverse is applied at the various speeds are indicated in the diagram Fig. 1B, in which the figures are marked a, b, c and d, the letters corresponding to those denoting the bearing under stress in each case.

Working these resultants out graphically, the compounded stresses on bearings a, b, c and d are found to be as follows when the reverse is applied:

$$a_r = \text{stress on bearing a at reverse, composed of } \frac{212 \times 35}{68} = 109\ \text{kg.}$$

$$\text{and } \frac{254 \times 12}{68} = 45\ \text{kg.; resultant} = 150.\text{kg.}$$

New Farcot Two-Cylinder Two-Cycle Revolving Motor

PARIS, July 14—There is a considerable amount of originality in the design and construction of the Farcot two-cylinder two-cycle revolving motor now undergoing tests at the laboratory of the Automobile Club of France. As in the case of a very successful French seven-cylinder motor, the designer causes cylinders and crankcase to revolve round a fixed crankshaft. By adopting the two-cycle principle, however, he has got away from the complication of valves and valve mechanism, has reduced weight, and simplified the motor by the abolition of all gear wheels except the magneto driving and driven pinions.

The two cylinders are machined out of a solid bar of nickel steel, together with their radiating fins. Bore is 4.7 inches and stroke 3.9 inches. There is no separate crankcase, the base of each of the two cylinders forming this chamber. The two halves are dovetailed together and secured by an encircling collar, which gives extreme lightness, together with a perfectly gas-tight chamber. The cylinders are offset in relation one to the other in order to allow the use of a two-throw crankshaft of the ordinary type. There is nothing unusual, either, in the design of the connecting rods. Aluminum as the material for pistons is an innovation which, after a series of experiments, has been found satisfactory by the inventor. The pistons are a die casting, ribbed in the head for

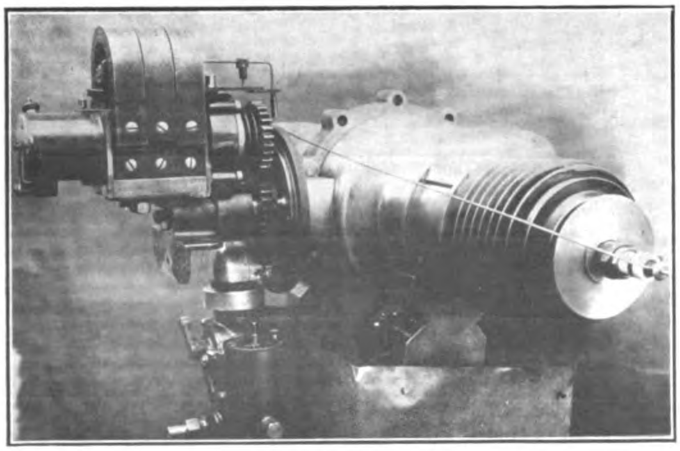

Fig. 1—Farcot 2-cylinder motor of the revolving type, showing the magneto and details of the timing equipment

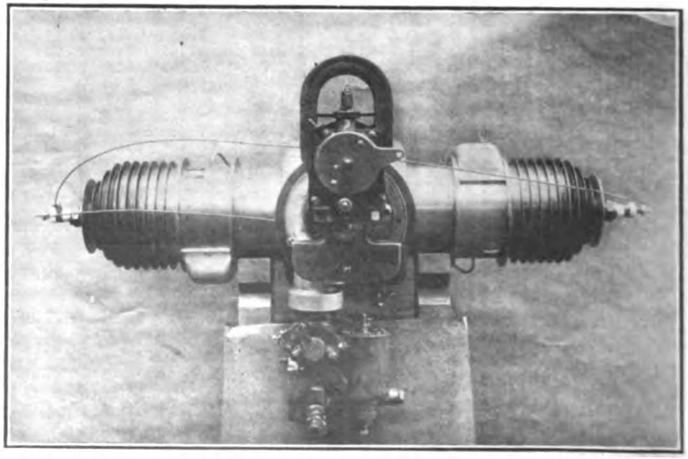

Fig. 2—Farcot 2-cylinder 2-cycle motor, side view, showing location of the carbureter and other details

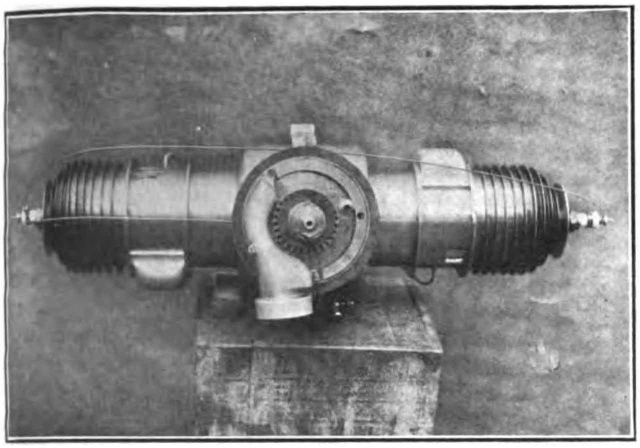

Fig. 3—Opposite side view of Farcot motor showing the exhausting device and methods of construction

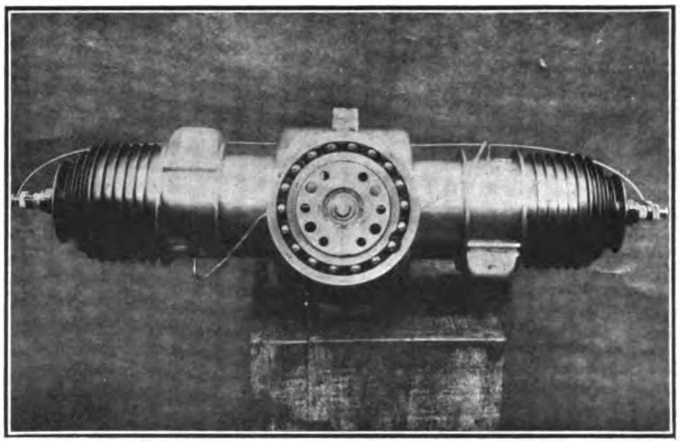

Fig. 4—View of the motor with the magneto removed showing the ball-bearing crankshaft and simplicity in designing

strength, provided with two rings side by side, and carrying the usual type of baffle plate in order to deflect the gases away from the exhaust port.

A standard type of carbureter is employed, with connection to the motor by a single straight length of intake piping. On the end of the crankshaft is a fixed disc with an oval port corresponding with the end of the intake pipe, and in friction with it a revolving disc, also provided with an oval port, revolving with the crankcase. On the upstroke of the pistons the revolving disc uncovers the port on the fixed disc, allowing a mixture to be aspired into the crank chamber. After compression the charge is passed through a series of ports in the walls of the piston, corresponding with similar ports in the walls of the cylinder, into an aluminum chamber applied to the outside of the cylinder and communicating, according to the position of the piston, with both the crank chamber and the combustion chamber. The baffle plate on the piston head deflects the gas towards the upper portion of the cylinder, away from the exhaust port.

Ignition is provided for by a high-tension magneto mounted on a bracket above one extremity of the fixed crankshaft, and driven by a gear wheel on the crankcase. The magneto driving and driven pinions are the only gear wheels in the motor. The spark plugs are in the head of the cylinders. Lubrication is under pressure from a belt-driven lubricator through the hollow crankshaft to the main bearings and the connecting rod ends, with a separate lead, by external pipe, to the cylinder walls.

In complete running order the motor weighs 70 pounds and develops 30 horsepower at 1200 revolutions. A motor on the same principles, but with four instead of two cylinders, has also been constructed with a total weight of 110 pounds for 45 to 50 horsepower at 1100 revolutions. The illustrations give an excellent idea of the appearance of the motor.

Some Light-Weight Motors from Europe

STRAINING many points which experience in the automobile field has well-nigh established as essential for reliability of the internal-combustion motor, designers of engines intended for aviation purposes have gone at the task of creating new relations between power and weight with an ardor which no other purpose than that of gaining prominence and laurels in the new spectacular form of locomotion could have produced. The long-stroke motor, suddenly looked upon with so much favor, may be the upshot of other considerations, such as the keen desire for fuel economy, which is much more pronounced in Europe than here, owing to the higher prices for gasoline, but it is safe to say that air cooling, the two-cycle system and the revolving-cylinder systems would never have gained their new and enthusiastic votaries but for the prevalence of greatly exaggerated notions of the desirability of minimum weight in the power plant of aeroplanes. Though the rage for lightness has already given birth to highly interesting and promising developments, same reaction against this tendency has already made itself felt. It is becoming understood that not one tittle or iota of reliability should be sacrificed in order to enable the aspiring but perhaps indiscreet aviator to leave the ground easily with a machine of indifferent merit, and that the good aviation motor should be one which might be turned to account for automobile or other earthly purpose without compromising in the least with any other requirements than perhaps that of low cost of production. Even as compared with the motors which in the past have been produced especially for racing automobiles at a cost which at first forbade a wide commercial application, and in which lightness was also a desideratum, the aviation motor is the more exacting, with regard to reliability, since it is necessary that it shall be wholly automatic in its lubricating and cooling systems. On the other hand, the demands born of long-distance racing for a motor capable of being worked at its very highest power development for a very long time without giving trouble, are not at present emphasized to the same degree for aviation motors, it being particularly desirable that the motor which drives the aeroplane shall possess a considerable reserve over and above the power normally employed for flight. All told, the aviation motor, rationally conceived, seems to promise a more direct application to automobile purposes than the quondam racing

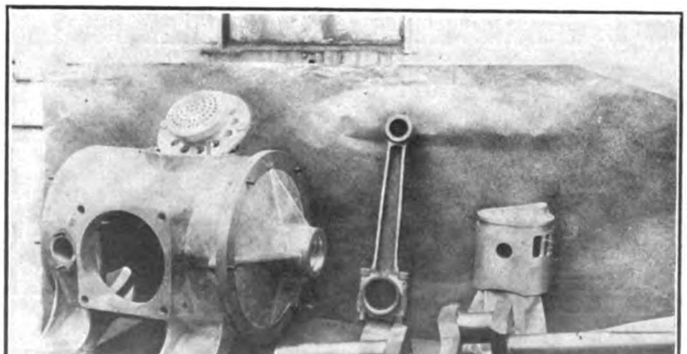

Fig. 5—Component parts of Farcot motor showing the crankshaft, connecting rod and other parts

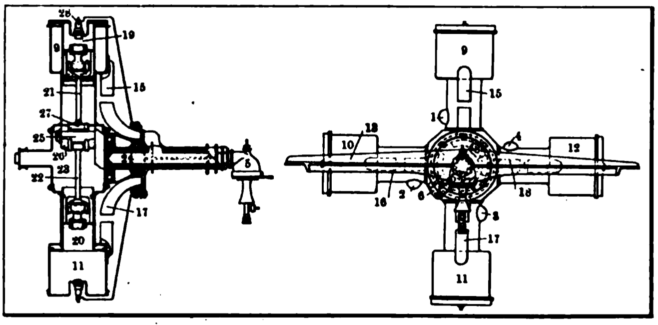

Fig. 2—Sectional views of the Palous & Beuse revolving cylinder two-cycle motor

motor did, and, as it was almost invariably found that all the important advantages in any new racing motor, whatever was its initial price of production, could be duplicated at nothing more than ordinary cost after those advantages had been ratified by experience and factory methods had been applied, it may be assumed that the efforts devoted to the development of the long-stroke, two-cycle, air-cooled, light-weight and high-powered power plant for the road of air will eventually exert a stronger influence in the whole motor field than the automobile racing motors ever did.

There seem to be only two avenues of escape from this conclusion, one in assuming that none of the aviation motors will reach perfection except by returning to the present automobile type; the other, which is even less reasonable, in advancing the assertion that there is something intrinsically inconsistent with low cost of production in the development of those designs which have latterly seen the light of day and of which extreme lightness is at present the most attractive and least disputed feature.

At the present moment the aviation movement has at least broken that trend of conservatism which threatened to throw into oblivion all scientific pursuit of motor perfection in favor of a widespread imitation of certain successful types, and a large number of able designers have been put to work in the world's experimental department, where progress is manufactured from the raw material of fresh ideas, as well as from old ideas once prematurely discarded, but which are showing new values under new conditions, especially the highly improved shop facilities for giving adequate material expression to the designer's conceptions. It would for example have been next to impossible ten years ago to have found any combination of foundry, machine shop, workmen and designer by which the fourteen-cylinder revolving Gnome could have been turned out at commercial cost and in fit condition to run.

Some obvious short cuts to aviation results—which are identical with the capturing of fat prizes at the many meets—still mar the renewed efforts, here and there. The entire genus of motors with revolving cylinders is looked upon by many in that light, on account of the remote chance of having it applied to other uses, but it is especially the separate exhaust from each cylinder through the cylinder heads, a truly pyrotechnical display, which proclaims a serious difficulty in their design, since it is evident that even for aviation the time is not very distant when the exhaust will require to be taken care of in a civilized manner. Fuel waste and lack of flexibility in the power output constitute another marring defect, forgiven at present only because lightness is the concomitant feature which is overvalued.

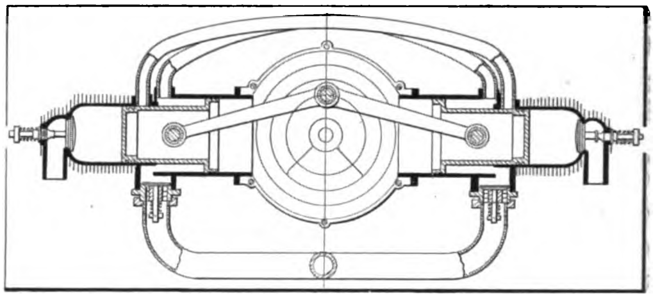

Fig. 6—Sectional view of the Anzani two-cycle motor.

The conservative British Green motor exemplifies prettily what may be done in light construction without departing far from automobile practice. It weighs little more than 4 to 5 pounds per brake horsepower, and its constructive peculiarities may be observed directly on the accompanying drawing, copied from *Der Motorwagen*. Most notable are the following: Dead spaces around the valves are wholly avoided, giving high compression with satisfactory precautions against premature ignition and overheating. Valve parts are interchangeable and easily dismounted. Valves are actuated from the camshaft extending over the tops of the cylinders and enclosed in an aluminum housing, whereby reciprocating masses are reduced as well as dimensions and vibrations. The aluminum housing may be readily unhinged. The water jacket embraces the whole upper portion of the cylinders, including the walls adjacent to the valves. It is tightened at the bottom joint by means of a rubber ring, so as to permit expansion without leak. The combination of parallel and ball bearings for the crankshaft and flywheel should secure uniformity of wear which in turn should afford a good guarantee against the early development of knocking and other irregularities which sooner or later develop into something worse.

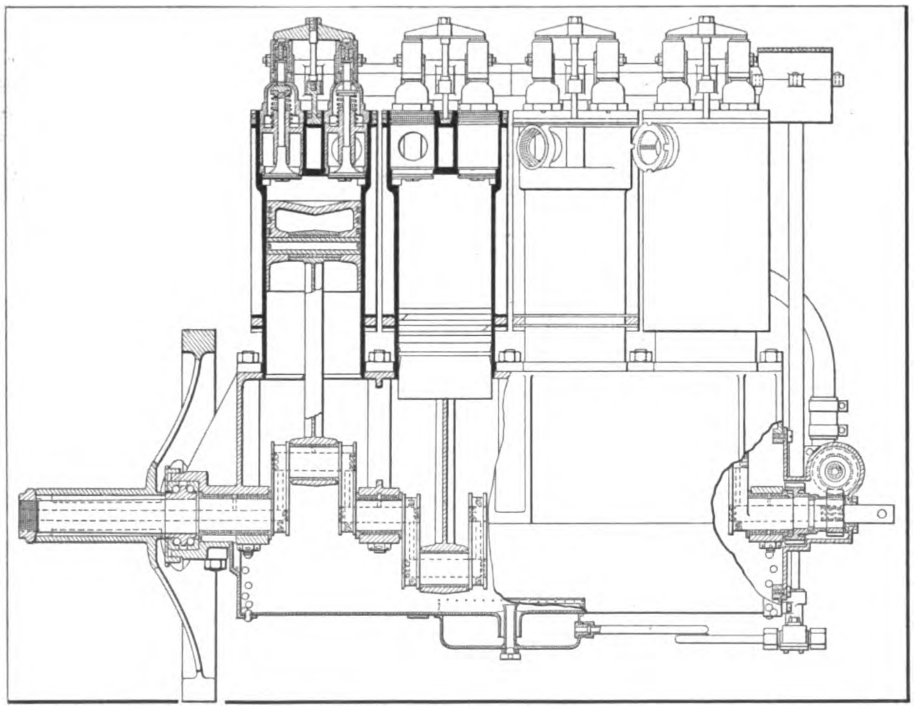

Fig. 1—Construction drawing of the Green motor

Much crankshaft weight is saved by the multiple V-type, of which the Miller motor, built in Italy, is an example. The cylinders are 50° apart, and are fired in the order 1, 3, 2, 4, making the angular distances between explosions 100°, 310°, 100° and 210°, which makes the regularity a little better than for the ordinary four-cylinder V-type motor with two pairs of cylinders 90° apart. One of the connecting rods is knuckled so as to embrace the crankpin in the usual manner, and is provided with a rock shaft upon which the three other connecting rods work, this being a simple method for overcoming a mooted difficulty in the multiple V-type and one which apparently works out to satisfaction. With regard to the intake valve there is a return in this motor to the automatic type, which has the advantage of lightness and is, perhaps, as good as one mechanically operated when no extremely low throttling is required. The details of this automatic intake valve are shown in illustration. *A* is an aluminum tube which connects directly with the carburetion chamber of the carbureter *C,* of ordinary but highly simplified design. The crankcase forms a partitioned oil reservoir with splash action, but a force system is used in addition. At 1100 r.p.m. the Miller motor, with four cylinders of 100 mm. bore and 130 mm. stroke, gives close to 40 horsepower, and at 800 r.p.m., which should correspond to about 30 horsepower, the fuel consumption was found to be 11.650 litres for one hour of 265 grammes per horsepower, which is as low as for good motors of much heavier construction. The weight of the Miller is 70 kg., but the lightness is the result of the choice of type rather than of any skimping in the dimensions of parts. *La Vie Automobile* mentions the fact that this is one of the few motors for aviation whose makers furnish a propeller designed especially to agree with its power and speed, thus recognizing the great loss of efficiency which follows when the matching of these two elements is left to chance or must be effected by gearing.

The combination of the revolving with the two-cycle type offers an opportunity to dispose centrally of the exhaust. This is done in the German Palous & Beuse motor by means of a pocket in the edge of the pistons, which is arranged to register with an outlet port at the end of the downstroke, on the plan of the auxiliary exhaust of several air-cooled automobile and two-cycle marine motors. The P. & B. aviation motor has four revolving cylinders of 150 mm. bore and 140 mm. stroke, completely valveless, and weighing, everything included, 1 kg. per horsepower. The construction is shown in two sectional views. The manner of operation is as follows: The gas mixture is ignited when the piston 19 reaches the top of the stroke, but meanwhile this piston has drawn in a fresh charge through the pipe 15, during the upstroke, and has filled the chamber 9 completely with the mixture. By the downstroke this charge in chamber 9 is compressed, and, after the piston has reached the entrance to induction pipe 15, the gases enter through this opening in the cylinder, and while this takes place the exhaust port is also becoming free, as above referred to. The ignition, as well as the regulation of the gas mixture, takes place through the curved aperture 8, which is opened and closed by a fibre ring 7, on which the ignition roller rotates. The carbureter is of the spray type, without float. While the cooling is effected mostly by the rapid revolving of the cylinders without recourse to flanges, the distribution and compression of the fresh charge all around the cylinder contributes to the desired effect.

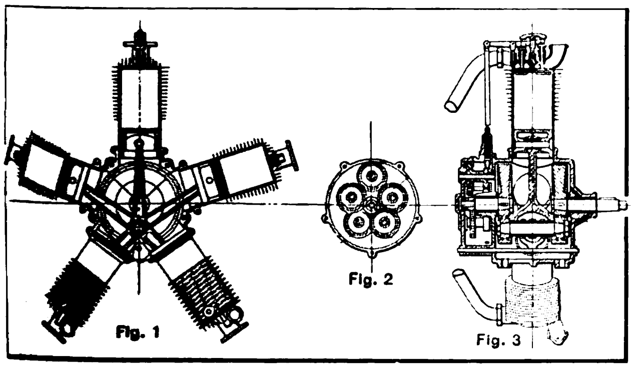

Fig. 3—Sectional view of the Anzani five-cylinder, four-cycle motor

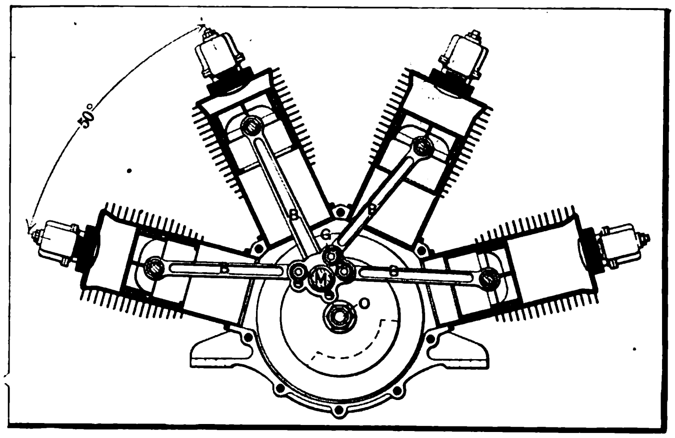

Fig. 4—General construction of the Miller motor

Anzani's two-cylinder, two-cycle motor, giving 30 horsepower, with a bore of 95 mm. and a stroke of 200 mm. (3 7/10 inches by 7 4/5 inches), and weighing 130 pounds, all included, is an air-cooled engine, but not of the revolving type. The cylinders are bolted to a vertically divided crankcase of aluminum in the usual way. The two pistons move together in the same direction with the two connecting rods attached to one crank pin. The internal flywheel is drilled to pare down weight. All gear wheels are avoided, the two-cycle system admitting of operating the exhaust valves in the heads of cylinders from a single cam on the crankshaft, and the magneto is also operated from the crankshaft. The accompanying sectional view shows the double bore of cylinders and the enlarged diameter of the lower end of the piston. At the head of the wide-diameter portion of the cylinders is a port into which is mounted an intake pipe with an automatic poppet suction valve, and the carbureter is on the middle of this length of piping. Each cylinder aspires the gas mixture for the opposed cylinder, compresses it, and drives it across through one of the two transfer pipes shown overhead, ready for use in the other cylinder as soon as its own power stroke is completed. By means of a very large exhaust valve, only one inch less in diameter than the bore, and by a one-fifth lead in the exhaust valve opening, mixing of the incoming charge with the exhaust is minimized. While this motor has been used largely on Blériot aeroplanes, there is a significant absence of reports with regard to its ability to remain cool, and Anzani has created another type which is a four-cycle, five-cylinder, star-shaped engine, weighing 176 pounds, and developing 50 horsepower. The cylinders are 105 by 120 mm. (4 by 4 7/10 inches) and are screwed into the crankcase. All the pistons work on a single throw crankshaft, each connecting rods clasping the crankpin in the usual way, so that all pistons have the same travel, unlike the Miller engine and other star-shaped or revolving cylinder motors in which only one connecting rod has the full length. The explosions in the Anzani five-cylinder motor take place in the order 1, 3, 5, 2, 4, at regular intervals of 144°, permitting ignition by high-tension magneto turning at 5/4 the speed of the crankshaft. Instead of a camshaft, there is a small pinion on the end of the crankshaft driving four independent pinions and cams, and a fifth pinion receiving its movement from one of the others, an arrangement which is probably dictated by lack of transverse space, but also serves the purpose of affording independent adjustment of the individual valves. The lubrication is by means of a pump driven from the crankshaft, with a collector to return excess oil find-

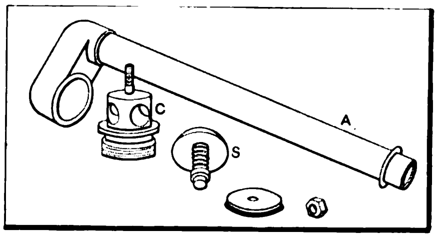

Fig. 5—Valve parts of the Miller motor

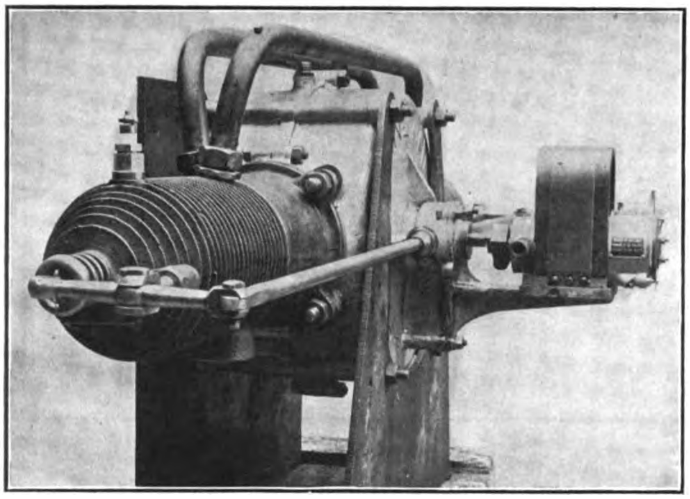

Fig. 7—Anzani's two-cycle, two-cylinder, air-cooled, 80 H.P. motor

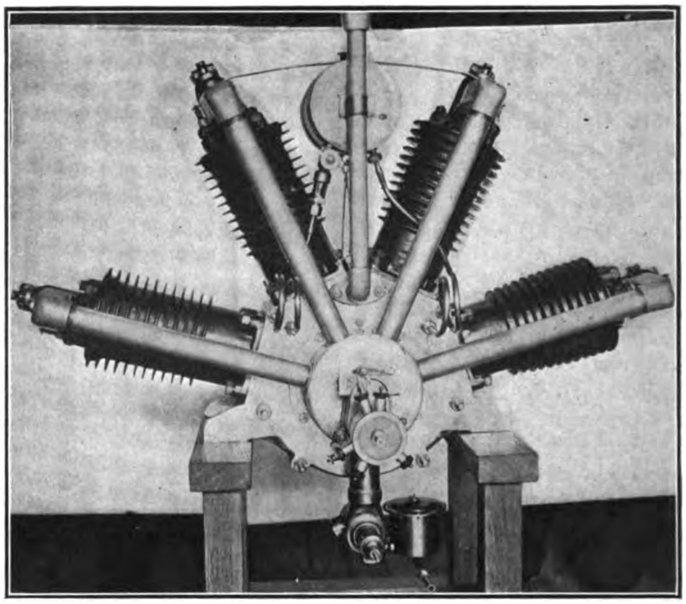

Fig. 3—The Miller aviation motor, built in Italy

ing its way to those cylinders whose heads are down. Both intake and exhaust valves are in the cylinder heads, and are operated by a double rocker arm similar to that used in the Panhard aviation motor referred to in this article. The carbureter consists of a cast aluminum choke tube mounted on an aluminum saucer, from the center of which rises a vertical nozzle. The base of the tube is provided with air openings and the gasoline flow is regulated with the conical-head screw shown in the illustration. In an aeroplane machine this screw is turned off or on by means of a Bowden wire. The weight of this carbureter is only a little more than one-half pound. In practice it sends a steady semi-liquid flow into the hot induction tubes. Its fuel economy is probably slightly better than that of the surface evaporators used in 1897, and its small weight is therefore more than counterbalanced by the greater amount of gasoline to be carried by the aviator for any but very short exhibition flights.

One of the most conservative aviation motors is the four-cylinder Panhard with which the Tellier monoplane is equipped, and with which flight records have been made quite equal to most of those made with motors of much lighter weight. As it is practically an automobile motor with copper water jackets, steel cylinders with separate heads and concentric valves, an illustration of the valve mechanism will serve the purposes of this article. The cylinder head is a Y-shaped casting, one arm of which is bored out to receive the intake manifold, while the other arm forms a bracket for the special rocker arm operating the two valves, and its stem is bored to house the valves. In the upper portion of this housing, with reduced diameter, is inserted a helical spring, which maintains the intake valve in position on top of the cylindrical exhaust valve bell, and into the top of the housing is screwed a cap, against which the external exhaust valve spring abuts, and which also carries a rocker arm, by means of which the intake valve is operated. While the short end of the rocker arm depresses the exhaust valve on the downward thrust of the main rocker, the long end raises the extremity of the short rocker arm, on the upward lift, and depresses the intake valve. Each pair of valves is operated by a single cam and a single tappet rod. The water-cooling connection between the cylinders is by means of a narrow rubber-bound collar, as plainly seen in two of the illustrations. This motor develops 40 horsepower, and it is worthy of belief in its stability on account of the service already rendered by the type, resulting in efficiency of performance and high thermal results. It is stated that the fuel consumption is only 3 gallons per hour at full power.

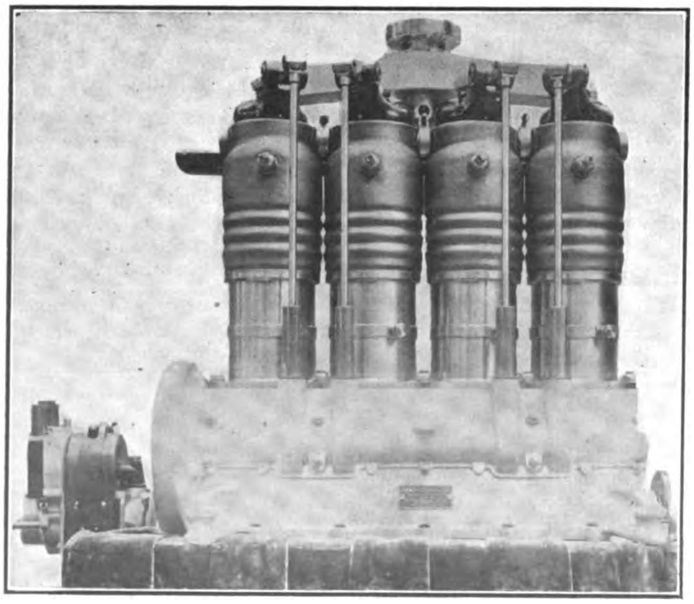

Fig. 9—The Panhard-et-Levassor aviation motor

For a considerable time the seven-cylinder Gnome motor held the position as the most pronounced deviation from current practice, both with regard to lightness and design, and it has been frequently described. The cylinder walls are only ½ mm. thick, or about one-fortieth of one inch, though bore and stroke are approximately 4½ inches and the centrifugal strain arising from the very rapid revolving of the whole engine must be very considerable. The cooling flanges contribute greatly to strength, however. When running full power this motor makes a thundering noise, and sends smoke and greasy spray in all directions, radially, as the exhaust is in the seven cylinder heads and passes out unchecked, while the lubricant is either a mixture of mineral and castor oil, or pure castor oil, which has to be supplied in profusion. The power development reaches 50 horsepower, however, with a 'total weight of 150 pounds. The inlet valves are in the pistons and are auto-

Fig. 12—The floatless carbureter of the Anzani motors

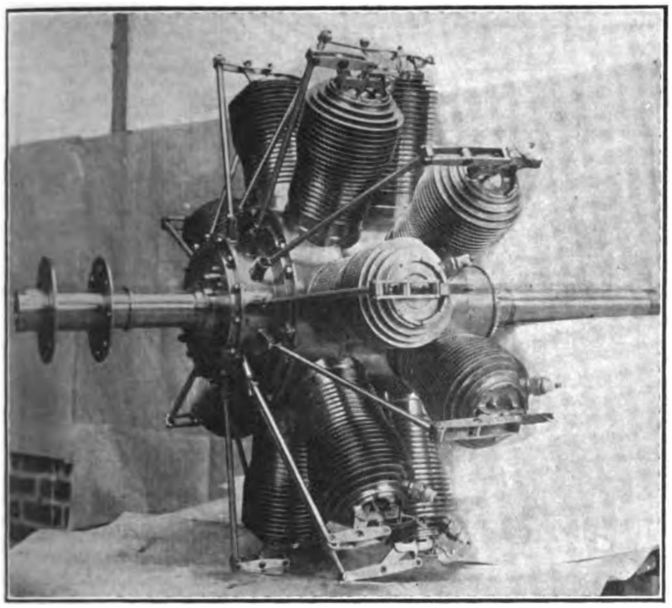

Fig. 13—Gnome 14-cylinder revolving, four-cycle, 100-hp. motor

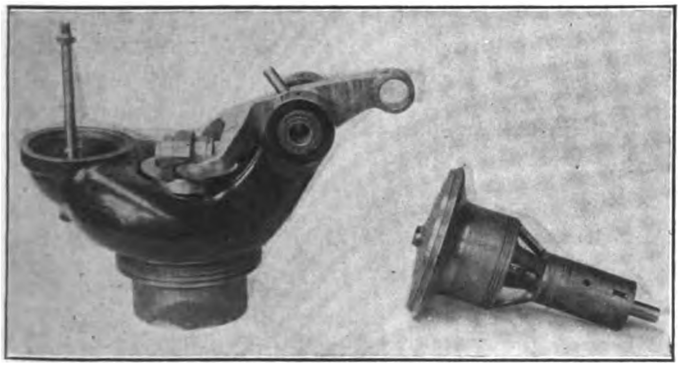

Fig. 11—Cylinder head and concentric valves of Panhard motor

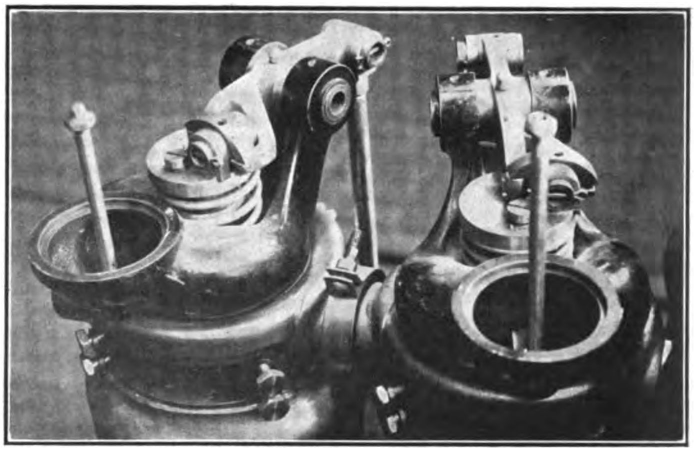

Fig. 10—Valve-operating mechanism of Panhard aviation motor

matic. The pistons, by the way, are provided with only one cast-iron piston ring each, close to the top of the piston, but this single ring is surrounded with a ring of L-section spun from a strip of brass and kept expanded by the pressure of the cast ring. The inlet valve is of the ordinary mushroom type, but its stem is engaged by a pair of levers which terminate in counterweights arranged to counteract the tendency to opening of the valve which naturally results from centrifugality. The faster the motor revolves, the harder the counterweights press upon a flat spring which serves as valve-closing spring. The effects are balanced so nicely that the centrifugal action is neutralized and the suction of the piston, in drawing in the gases has no more nor less work to do in overcoming the valve spring than if the motor were not of the revolving type. With keen logic the designer has perceived that the inaccessibility of these valves would not matter, as the aviator, anyway, has no time to fix a valve giving trouble.

This motor has now been distanced by a 14-cylinder Gnome of the same general construction, but in which the effects of a gasoline turbine are even more strongly marked. The horsepower is increased to a round 100. It is practically a double seven-cylinder Gnome, one placed staggered in relation to the other on the common crank case, for each has its own magneto and its own lubricating pump. The operation of all the valves from the same side, despite the far-over reach for one set of the valve rods, unites the two motors into a single engine to the eye, and the whole weighs 260 pounds, being a weight saving of 40 pounds, as compared with doubling the weight of the seven-cylinder species. The circular crankcase is machined from a steel casting, and each cylinder is secured in position by means of an internal-locking ring. The crank pin, which is single in the seven-cylinder motor, is here double-opposed, with seven connecting rods acting on each crank. The whole mass of cylinders and valve-operating parts revolves around this shaft mounted upon two ball bearings. The carbureter is a brass elbow, with a series of air holes, surrounding a spray jet and provided with a mechanically operated sleeve giving additional air for starting cold, and a butterfly throttle valve. The motor can be throttled down to run at 300 revolutions. The gas mixture is drawn through the hollow crankshaft into the crank case, where it is acted upon by the automatic intake valves. Lubrication is also effected through the fixed crankshaft by means of two copper tubes passed through the same and fed from two force feed pumps. The pure castor oil, which is the material preferably used, passes to each of the two sets of cylinders through fine perforations in the shaft.

Digest Along Technical Lines for Engineers

Methods for joining aluminum parts, other than by flanging and riveting, are reviewed with the special object of determining the maximum strength of true soldering joints. With regard to autogenous welding, Spring has shown that two pieces of aluminum heated to 400° C. and pressed together are slowly united. W. C. Heraeus, of Hanau, heats pieces of aluminum by means of a hydrogen blower and hammers them together. In this manner tubes are formed almost equal to drawn. Rapid oxidation is the greatest hindrance to soldering and welding. When metallically clean, aluminum at once takes on a film of oxide which effectually prevents the uniting with another piece of metal coated likewise. There is needed a flux to prevent or dissolve this formation. The "Autogen" Company has a process for dissolving the oxide and forming a slag which isolates the weld-place airtight. For true soldering a great number of solder preparations are used corresponding to the great number of aluminum alloys in the market. A. Minet states in *L'Electrochimie* that Otto Nicolai uses a zinc-tin alloy and gets firm joints by covering the solder-place with powdered chloride of cadmium or iodide of cadmium. This is believed to be the process referred to later in the tests of "Grubelin" flux. Dr. Edw. D. Self says the skin is a film of clay, but gets results, by using vaseline or paraffine as flux, with any one of four solder alloys: (1) One part silver and two parts aluminum; (2) 85 to 95 parts tin and 15 to 5 parts bismuth; (3) 99 parts tin and 1 part bismuth, but this is improved by adding 1 part aluminum; (4) 90 parts of tin, 5 parts bismuth and 5 parts aluminum. He states that good cleaning and cautious heating (not exceeding requirements for fusion) are necessary and that the solder should be put on with a soldering iron. W. S. Bates stated before the American Chemical Society at Chicago that 70 parts of aluminum and 30 parts of tin gives a very firm joint, but that in course of time the molecules change their positions and the joint gives way; also that 81 parts of aluminum with 19 parts of copper, while not so fusible as the other composition, makes a lasting joint. But the best results, Bates says, are obtained with 70 parts of aluminum, 20 of tin and 10 of copper or silver, and a joint made with this solder proved perfectly durable and was not affected by immersion in water for two months. For the soft solders, Bates used as a flux chloride of zinc, stearin, soap, sugar, chloride of mercury and some iodides; for the hard solders and higher temperatures he used borax, fluoride of alkali, chloride of lithium.

Some time ago a ready-to-use aluminum solder, together with a flux designated in trade as "Grubelin," was brought into the market. The fusion point of the solder is 230° C. or no higher than that of tin. With this, it seems, sheets, tubes, wires and even cast pieces may be joined strongly and lastingly. By reason of the low melting point, even sheets and wires not more than one-tenth of one millimeter in thickness may be soldered. In using this process, the work is cleaned with a scraper, not with sand or emery, and heated by means of a Bunsen burner or a blowpipe, small pieces of the solder being placed on the work after the latter has been sprinkled with the flux. But the work may also be done as soft soldering, the solder being rubbed on with the heated soldering-iron till the surface is covered. By the rubbing, the oxide skin just formed by the heat is removed.

This was tried in the Royal (Prussian) Laboratory for Testing of Materials, with aluminum sheets bought in the open market. Strips of 30 mm. width were cut from the sheets and soldered with varying overlapping. A scraper was used to brighten the surfaces, and the areas were at once covered with solder, a copper wire being used to distribute it. The two areas were placed against each other, held with two tongs and heated over the Bunsen burner. As soon as the solder began to melt, the copper wire was used to apply a little more of the solder along the edges of the seam, and then the work was allowed to cool under the pressure of the tongs. The soft soldering part of the test was carried on in the customary manner, but without sal-ammoniac or water. To obtain a basis for judging the strength of the joints, the strength of aluminum strips 30 mm. wide was first determined in their original condition and subsequently after they had been heated in the Bunsen flame. The result of this was as follows:

Sample No	Condition	Measurements			Breaking Load	
		Width cm.	Thickness cm.	Area of Section sq. cm.	Observed kg.	Tension kg per. sq. cm
1	As bought	3.0	0.05	0.15	330	2000
2	As bought				317	2100
3	Heated over Bunsen Burner				132*	880
4					164	1090

From this it is seen that the aluminum sheet loses about one-half its strength in being heated for soldering, and consequently the soldered joint must for this reason alone be weaker than the sheet in its original condition. Probably the rolling process gives the sheet the higher strength which it loses by heating. The data of the solder joints are given in the following table:

Sample No.	Dimensions of Seam		Method	Done by	Breaking Load		Location of Fracture
	Length cm.	Width cm.			Observed kg.	Tension kg. per sq. cm.	
1	1.8	3.0	heated over Bunsen burner	by inventor of process	156	1040—1	—1 = outside the soldered area. —2 = in the soldered area. —3 = in the seam —4 = in seam when adjusted for test.
2	1.2				158	1050—1	
3	1.6				150	1000—2	
4	1.0				136	910—2	
5					156	1040—1	
6	1.0				148	990—2	
7	1.0				138	920—3	
8	1.0				134	890—3	
9	1.0		with soldering iron	by locksmith employed at test station	...	—4	
10	1.0				50	330—3	
11	1.0				...	—4	
12	1.0				156	1040—2	
13	1.0				66	440—3	
14	1.8		cautiously over Bunsen flame		258	1720—1	
15	1.2				214	1430—2	
16	0.6				200	1330—1	

Samples 4 to 8 and 9 to 13 were produced by soldering two sheets of 16½ cm. width to one another, so that a seam was made of 16½ cm. in length, and these sheets, so joined, were then cut in strips of 3 cm. in width, with the seam in the middle. The tests show that the firm joints may be made of sheets 0.05 cm. thick and that the strength of the joints, in the case of rolled sheets, depends on the heat. Sample No. 14 gave the best results through very cautious soldering, the strength being reduced only 330 kg. per square cm., or 16 per cent. below the average strength of the sheets before heating, which was 2,050 kg. In other words, the soldered joint reached 84 per cent. of that of the material itself, while the latter by mere heating to red would have lost 50 per cent.

A very recent soldering method consists in nickel-plating the parts to be joined and then proceeding to solder with usual tin solder and soldering-iron. This method is, so far as experience has shown to date, dependable, besides being easy to carry out.—*Metall-Technik*, Nos. 20 and 21, 1910.

An immediate patina for copper and bronze, taking the place of the offensively bright metallic surface, may be produced at a pinch by very simple means. The method is not one that gives absolutely lasting results, as when an etching solution is used, but it is quicker and cheaper and lends itself to many variations in the shades. It consists simply in sandblasting the object until the metallic brightness has given way to a matt effect, then brushing into this matt surface powdered dry coloring matter, as fine as possible and of the main shade which it is desired to obtain in the finished article. Usually Paris green or chrome green with an addition of brown or black will serve the purpose; even a powdered brown alone will do. The metal takes a satiny appearance and a light after-brushing will remove an excess of color. There will always remain an adhering coat of coloring matter in the minute furrows and indentations caused by the sandblast. The object is then dipped in a bath of transparent varnish or shellac and left to dry in a dust-free drying room. The shellac does not only protect the coloring matter, so it will not readily wear off, but also imparts a lustre to it.—*La Vie Automobile*, July 9.

Complete independence of cooling methods is promised by Martin-Saxton, an engineer, who proposes to lengthen the cylinder to make the lubricated and tight-fitting lower portion of the piston work in the lower continuation of the cylinder, this continuation being isolated from the upper portion by a non-conductive ring, and on top of the lower portion of the piston to have a loose-fitting cylinder which is independent of lubrication.

Manual training at universities.—The university of Göttingen has made arrangements by which science and medical students may learn the practical parts of laboratory and experimental work at the manual training school maintained by the city of Göttingen. The courses for the students remain under the direction of the university authorities and are paid for through the latter.—*Werkstatts-Technik*, July.

Aviation News of the Week

FOLLOWING the line of experimentation laid down by Glenn H. Curtiss when he dropped fifteen out of twenty-two bombs within the outlines of a battleship while flying at full speed and at varying elevations in his aeroplane at Keuka Lake, the United States Government has just completed a lot of research work to develop the possibilities of the aeroplane as a military and naval factor.

The conclusions of the officers were that there is no firearm in existence that can cope with the perfected type of aerial torpedo craft and that such perfected aerial torpedo craft will become stable adjuncts of the navies of the world within five years.

In the way of protection, the tests were intended to prove that steel nettings or similar devices would shield ships, men or forts from bombs or torpedoes projected from aeroplanes. According to reports rendered to the War Department, the momentum caused the experimental shells used by the authorities to crash through a steel wire net so closely woven as to equal the resistance offered by a sheet of half-inch steel.

The main points urged by the advocates of the aeroplane are as follows: Small possible casualties; low cost; small target; invulnerability of machine and crew through simple protective armor; efficiency against ships, troops, or forts; mobility and facilities for gaining information of the disposition of an enemy's forces.

Inspection of aeroplanes is being seriously considered by the United States Government, according to recent announcement. The French Government is also about to install some sort of an inspection system.

An even dozen entries for the *World-Post Dispatch* prize of $30,000 for a flight between St. Louis and New York have been made or are about to be made. Among the entrants are the following: Harry S. Harkness with an Antoinette monoplane; Louis Strang, a Bleriot; Philip Wilcox, Joseph Seymore, George Russell, Tod Shriver, Walter L. Fairchild, and Israel Ludlow.

Clifford B. Harmon, who may make a try for the prize, is trying to influence Louis Paulhan to enter the contest, but on account of the legal tangle that followed the last attempt of Paulhan to aviate in this country, there is small chance of his doing so.

Rheims Aviation Meet Brings New Results

The complete official results of the second annual Rheims aviation meeting are as follows:

Grand Prix de Champagne offered to the builder whose three machines fly the greatest total distance

	Miles
Antoinette monoplanes, Antoinette 8-cylinder motor......	1616
Bleriot monoplanes, Gnome 7-cylinder motor............	1430
Henry Farman biplanes. Gnome 7-cylinder motors......	1181
Sommer biplanes, Gnome 7-cylinder motors..............	850

Greatest Distance in a Single Flight

	Miles
R. Labouchére, Antoinette monoplane, Antoinette motor	211
Olieslagers, Bleriot monoplane, Gnome motor............	139
Tetard, Henry Farman biplane, Gnome motor............	115
Cattaneo, Bleriot monoplane, Gnome motor..............	111

Note.—Last year's record, Henry Farman, 111 miles.

Gordon Bennett Elimination Race, 62 1-10 Miles

	Time
Alfred Leblanc, Bleriot monoplane, Gnome motor........	1:19:13 3-5

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

WE believe that associations of bankers have the same right to combine against the automobile as the American Federation of Labor had to boycott the Buck Stove & Range Company. Gompers, Mitchell and colleagues are now facing serious action on the part of the Court for persisting along lines which are looked upon as in restraint of trade. Under the heading "Bankers Find Many Automobile Crazy" the New York *Herald* of July 22 printed a press despatch as follows: "Mount Vernon, N. Y., Thursday.—The Westchester Bankers' Association believe the people of the country are automobile crazy. On information received by its members at a session at the Briarcliff Hotel to-day, it was decided to look carefully into the applications of those who wish to borrow money on notes. If it is found that the applicant is to purchase an automobile, the bank will use extreme caution in discounting his paper. It was said that hundreds of persons have either mortgaged their homes or hypothecated valuable securities to purchase automobiles in the last six months." According to this Bankers' Association, a man who purchases an automobile is either lacking in sense or dishonest. It is of course gratifying to know that these bankers disapprove of dishonesty; it saves a bank examiner considerable worry to know that he does not have to watch a "string" of banks, but when a grave body of respected citizens makes the broad claim that purchasers of automobiles hypothecate valuable securities, the public at large will be justified in believing that they at least know the meaning of the word.

STANDARDIZATION, from the users' point of view, is a subject that has received but scant attention, due to the difficulty involved in combining the many opinions as they are voiced in the light of the experience of autoists, and to the further fact that makers of automobiles find it a sufficiently large task to bring about a condition of the standardization of the materials used in automobiles. Some of the illustrations presented in this issue of THE AUTOMOBILE are believed to be sufficiently terse to furnish a basis for thought, but it is not enough to merely ponder over a matter of such wide importance; the subject is ripe for action.

* * *

AT the pending meeting of the Society of Automobile Engineers one of the important subjects for discussion relates to the standardization of materials for automobiles. Naturally enough, engineers are sufficiently keen to understand perfectly the impossibility of bringing about a condition of standardization of cars on a broad basis before the materials used are reduced to a definite level. It is fitting that the question of the uniformity of materials be disposed of, and while this subject is far from new, the fact remains that much of the progress made by the Mechanical Branch of the A. L. A. M. was lost sight of during the last year or two, owing to inactivity on the part of the Mechanical Branch, and to a famine of material during the last year.

* * *

TO some extent, the scarcity of materials for automobiles was brought about through the lack of standards. The promiscuous ordering of materials, to the high disregard of stock sizes, introduced a high percentage of special work, and according to producers, made it unsafe to manufacture certain sizes for stock. If the Society of Automobile Engineers succeeds in establishing a set of standards for materials, producers will then be in a position to safely stock up, and the probability of a protracted famine will be materially reduced. Beyond this, a reduction in cost will be a reasonable expectation, and as a further benefit, the average of quality will mount to a higher plane.

* * *

IN reviewing the life and work of the Society of Automobile Engineers attention is called to the diversity of the subjects that received consideration, and a closer study for purposes of estimating will lead to the conclusion that the working of the Society has had a marked influence on the reform of steel mill practice. It has always been claimed that American steel fabricators stood for quantity production, and that they preferred to disregard questions of quality in the absence of quantity. This was another way of saying that the quality of American product was not up to the highest standard. Persistent work on the part of the members of the Society, coupled with the understanding that the good steel would be purchased from abroad if it could not be had from fabricators in this country, furnished the necessary inducement, and as it stands to-day the American mill is endeavoring to suppress its longing for tonnage sufficiently to make a foothold for quality. Great progress has been made and it now looks as if the time will soon be here when standard grades of steel will be regular from American mills.

RATIONAL conclusion in body designing is one of the subjects in this number, and it suggests a line of thought that must be uppermost with the men who participated in the late Glidden Tour, and with autoists in general who have had experience beyond the confines of paved streets and improved highways. It is a well appreciated fact that cooling, for illustration, is not a difficult process when an automobile is traveling at a high rate of speed, so that the only time when the radiator is likely to be overworked is when the car is traveling at a low rate of speed on an upgrade, or when the car is standing at the curb and the motor is slowed down with the spark retarded. Hooding over the front of the car, then, is advantageous in that splashes of mud are not permitted to destroy the radiating value of the cooler surfaces, nor is the low temperature of winter time likely to induce a considerable repair bill due to freezing water, whereas the relatively small opening, as shown in the hooded front, is sufficiently large when a fan propels the air as it does at low speeds. In the Glidden Tour improvised methods obtained for this purpose, but in the Prince Henry Tour the cars were so designed that the radiators were protected.

* * *

STRANGE to relate, the average autoist takes kindly to an aggregation of accessories plastered all over the exterior surfaces of his car; he overlooks the fact that at some time or other in his past one of the scenes that made an indelible mark on the tablet of his memory was the old-fashioned peddler and his store on wheels, with pots and pans dangling from hooks, placed with such a fine display of ingenuity that not a space remained uncovered. It is not believed that the peddler's wagon was regarded as a work of art; it was simply curious.

* * *

IS the peddler's plan a good one to be adopted for the automobile? But, if it is, are there not almost insurmountable disadvantages? The peddler kept an eye on his wares, despite the fact that a purloiner would scarcely be able to carry away more than a dollar's worth if he loaded himself down. In the case of the automobile, if nimble-fingered gentry succeed in appropriating a tire, to replace same will make quite a gap in the sparse pocketbook of the man who economizes for the purpose of buying and using an automobile. There are other angles to this problem. Tires depreciate quite as rapidly when they are hung on the side of the car and the sun beats down upon them as they do when they are serving their useful purpose on the wheels. One of the points brought out in this study of a body, as presented, is the fact that the spare tire can be placed in a dark and safe storage compartment, where it will keep without deteriorating, and the nimble-fingered purloiner of other people's property will give one disdainful glance at the body so arranged and take himself away empty-handed, he being afraid of work.

* * *

WHEN the chauffeur holds the wheel the owner sits in the tonneau and enjoys himself, he having the friendly protection which the tonneau affords; but when the owner drives he finds himself in a more strenuous atmosphere, and despite the protection offered by gloves, the hands get cold, and steering at the higher speeds becomes a dangerous occupation. Disregarding the fact that the chauffeur becomes hardened to his life, and exposure is less of a detriment, it remains to be seen that automobile bodies can be so designed that to occupy the front seat is quite as pleasurable as to lie back in the tonneau. The coming of the torpedo type of body was the last straw that broke the camel's back separating the automobile from its predecessor, the horse-drawn vehicle.

* * *

IN the engineering section a method of predicting the efficiency of internal combustion motors is presented with as much freedom from complication as can be expected in view of the importance of the subject and the complex thermo-dynamic problems involved. Certainly the time has arrived in the career of the automobile engineer when to build a motor first and find out afterwards whether or not it is good should be labeled as a high crime. The fact that a motor is made in the exact image of some other design, even though the model taken seems to be a work of art, is not sufficient ground for assuming that a condition of finality obtains.

* * *

IT is impossible to copy the design of a motor and obtain precisely the same results as those which are available to the original designer, because there is no way of taking advantage of the reasoning process which must be entered into by an original designer; hence danger besets the plan of the copyist, and success, instead of being assured, is represented by a tantalizing mirage, because while it is possible to copy the form, there is missing from the effort not only the precise materials used, but the condition in which they reside as well.

* * *

SMALL automobiles, once so prevalent in America, find favor abroad. When the foreign maker builds a big "road locomotive" he has a cast in his eye which reflects an American millionaire as a prospective customer, but when he builds an automobile for the native clientèle he puts a pair of blinds over the cast and designs on a basis of fuel economy, which is the paramount issue abroad. But it is not in the fuel economy alone that the small automobile sells. The depreciation of a car is in proportion to the power of its motor, or to the square of its speed on the road for a given weight, and in proportion to the weight, all other things being equal.

* * *

THERE is one other point that the foreign designer keeps in his mind's eye when he builds for home consumption. He remembers that the depreciation of an automobile is largely affected by its weight and speed, and that the life of the car is measured by the length of time it will serve silently, rather than by the distance it will make before it breaks down. In order to accomplish the intended purpose the parts are fashioned in such a way as not to court lost motion; they are protected from the accumulations of the roadside, and the method of lubrication is given the minutest scrutiny. It will be worth while for the American patrons of foreign products to notice the fact that they are the subjects for special consideration, but the time may arrive when the cost of maintenance will go up, due to the price of repair parts.

Possibilities of Automobile Construction

By HOWARD E. COFFIN, President Society of Automobile Engineers

THERE are many novel vital problems involved in automobile engineering and manufacture. The vast amount of experiments and testing necessary to bring the art to its present stage must be greatly added to.

Nearly all European and American pioneer automobile inventors, designers and builders started in the same general way. For sound engineering reasons certain paths of merit have been followed. As a result of many years' work by the best engineers, a popular design for large cars has resulted, after long trial of different features of construction separately appearing in early vehicles, such as the joint production of Peugeot and Levassor in the early nineties, and the production of Renault, Maybach, Bouton and some American engineers. The past several years have seen a substantially standard arrangement in small cars, so far as the principal component elements are concerned; here other features more largely the production of American engineers are dominant.

Prior to 1906, when the American automobile really began to reach its present high development, automobile engineers hesitated to co-operate openly, though they had followed the work of the contemporaries with interested closeness. Knowledge from the experience of others had greatly benefited the industry. Such blind co-operation exists in every industry.

Since 1906 open, frank discussion between automobile engineers has resulted in their mutual benefit and the benefit of the public. Realization that many heads are better than one brought through open discussion of the competent, newer and better methods of automobile construction.

There is no possibility of the Society of Automobile Engineers becoming a trade adjunct, but through its committee work and recommendations for standardization in specifications and materials, much practical benefit will result to the trade and the public; the technical value of the society to its members as a result of the presentation and discussion of theoretical papers, research work, etc., at the same time being continually increased.

No one of intelligence will to-day controvert the statement that all things in automobile engineering which can be, should be standardized—those things, the uniformity of which in no way stifles meritorious originality of design, but facilitates economic production and benefits the public. Many specifications for materials, and the method of treating and testing them, are standard; and there will be many more such specifications. Much good work in the way of simplifying seamless steel tubing specifications has been done; more of which will follow soon. The "deliveries problem" in the sheet metal field will be much less imposing within a relatively short time. There is a demand for standardization in the case of wood wheel dimensions and fastenings for solid tires; lock washers, brake and clutch levers; the various articles for the supply of which automobile manufacturers depend on automatic screw machine companies; round cornered square holes, spring shackle bolts; clutch leather.

There is an almost limitless field for good and an immediate necissity for action by way of standardization or such co-operation on the part of automobile engineers as amounts to the same thing. The automobile industry has sprung up like a mushroom, outstripping the detail engineering development which normally accompanies gradual growth. Lack of concerted work on the part of engineers, of standard reference tables, disregard of uniformity in material specification, can only result in greatly increasing the already existing great amount of needless expense, delay and vexation of automobile production.

A. A. A. Contest Board Disqualifies Buicks

At the last meeting of the Contest Board of the A. A. A., with Chairman S. M. Butler presiding, action in the matter of Buick models 16A and 16B was taken, disqualifying such models in all stock contests in which they participated during the race meeting at Indianapolis Speedway July 1, 2 and 4.

As cars of these models finished first in several of the races, the ruling will change the ownership of a number of purses and prizes and the effect on the general automobile contest situation may be radical.

The matter of the competence of Buick models 16A and 16B to enter stock car events was first brought into question at the Spring meeting at Indianapolis, when the cars were disqualified prior to the start. W. C. Durant, of the General Motors Company, made a sharp protest at that time, but was overruled by Chairman Butler.

When these cars were allowed to start in the recent races at Indianapolis it was supposed that the status of the models had been established, all of which adds to the suddenness of the blow. Mr. Durant left New York for Flint, Mich., early this week and nothing concerning the attitude of the General Motors Company could be learned, in his absence from the New York offices of that concern.

Mr. Butler, while making the announcement officially, would not comment upon its possible effect.

The general impression along Automobile Row was that the ruling is the first gun in what may prove a general engagement, the outcome of which may be a new alignment of the forces of motordom.

The possibilities involved are of such deep moment that few responsible leaders of the trade would hazard an opinion upon the matter.

Maryland Refused Motor Reciprocity

Baltimore, Md., July 25—Through Highway Commissioner Joseph W. Hunter, Pennsylvania has refused Maryland's overtures for reciprocal relations. In his letter to Motor Vehicle Commissioner John E. George, Mr. Hunter states that no matter what concessions Maryland may make, he has no authority to waive any of the provisions of the Pennsylvania motor car laws. This means that Marylanders who desire to pass through Pennsylvania or go to points north will have to pay the annual $10 license fee.

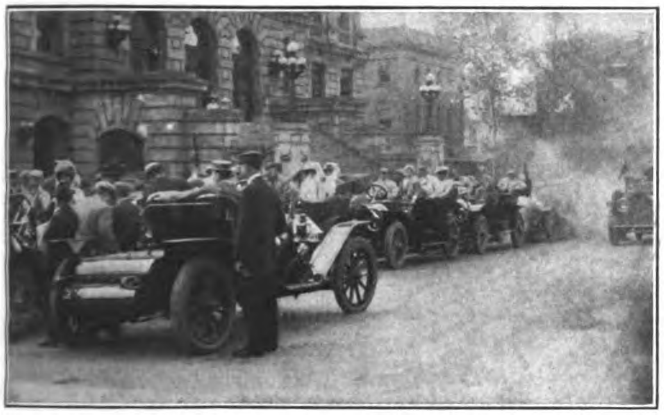
Marylanders will be at the same disadvantage that the laws of this State place upon Washingtonians. Persons in the District of Columbia are refused under the Maryland law a limited license at a reduced price for those who wish to go through Maryland. Thus Maryland seems to be getting a dose of its own medicine in consequence of the decision of the Pennsylvania authorities.

The District of Columbia authorities, because of Maryland's decision, have decided that Maryland motorists will have to pay $2 every time they want to go to Washington or pass through the District. And the motorists of all the States and sections are the ones who have to stand the hardship.

New speed rate notices have been designed by Special Officer Noah Walker, of West Arlington, to be placed along Park Heights avenue, the most popular thoroughfare out of the city. These signs explain the rate per hour permitted under the new law. The signs are of galvanized iron, circular in shape, a foot and a half in diameter. They will be placed on iron posts protruding less than two feet above the ground along the side of the highway. One side is painted bright red, while the opposite side is worded in large black letters with a bright yellow background.

Syracuse "Instructive" Run Proves Enjoyable Affair

SYRACUSE, N. Y., July 25.—The Automobile Club of Syracuse held last Wednesday its first contest for the B. E. Watson trophy, donated by a member of the club. It was an instructive run, so called, based upon the provisions of the new automobile law which takes effect in the Empire State August 1. A secret time was established by a committee of which President Hurlburt W. Smith was chairman.



Start of Watson-Cup Run from Syracuse Court House

The time, based upon all requirements of the new law, was fixed at 6:07 3-4 for a run from the Court House here to the Spring House at Rexford Falls, where dinner was taken, and return. The cup was won by T. E. Lawless, one of the new members of the club, in 6:06 3-4, just a minute faster than the set time.

Mr. Lawless's car was a Maxwell. Miss Nettie Grody won, with a Pullman, a handsome silver cup donated perpetually by the club to the woman driver coming closest to the secret time. Miss Grody's time was 6:03. Mrs. Henry E. Mills, in a Franklin, was next among the women with 5:50. There were three other women drivers. The men finishing nearest to Mr. Lawless's time were W. J. Latimer, 6:02, and F. L. Wightman, 6:10.

Thirty-seven automobiles started, carrying 173 people, and all finished. The total value of the cars making the trip was estimated at $111,000. No confetti was used in the trip to mark the way.

Ideal weather conditions prevailed, the roads were in fine condition, and the route was pronounced one of the most picturesque in the State.

A feature pleasantly noticeable was the interest displayed by residents of the villages through which the automobiles passed.

The mechanical experts on the trip considered it a good, hard test for the cars, some of which were four or five years old, and that the run was made with a total of four punctures, forming the entire list of mishaps, was considered a splendid commentary upon general automobile construction of the present day.

The official summary follows:

No. Name	Car.	Time
1—H. W. Smith (non-contestant)	Packard	....
2—B. E. Watson (non-contestant)	Oldsmobile	....
3—M. C. Smith	Amplex	5.06
4—George E. Messer	Franklin	5.14 1-2
5—H. W. Chapin	Thomas-Detroit	5.02 1-2
6—P. B. Ward	Winton	6.21 1-2
7—Charles Ludwig	Cadillac	5.35
8—P. E. Peacock	Buick	6.17
9—A. T. Brown	Packard	5.10 3-4
10—H. D. Weed	Speedwell	5.25
11—Strait & Shaw	Welch	5.36
12—D. Millen	Buick	5.35 3-4
13—R. P. Byrne	Speedwell	6.14 1-2
14—J. J. Barber	Pierce-Arrow	5.39
15—Mrs. L. P. Kellogg	Buick	5.39
16—Miss Nettie Grody	Pullman	6.03
17—Mrs. H. E. Mills	Franklin	5.50
18—G. L. Mardin	Selden	5.57 1-2
19—Charles A. Smith	Oldsmobile	5.58
20—A. M. Chase	Chase	5.45
21—E. L. Wright	Maxwell	5.51 1-2
22—A. J. Conine	Buick	5.46 1-4
23—F. L. Wightman	Winton	6.10
24—E. C. West	Stoddard-Dayton	5.59 1-2
25—George J. Arnold	Cartercar	5.47
26—Mrs. J. E. Heffernan	Knox	5.43 1-2
27—George J. Hessler	Franklin	6.16
28—W. J. Latimer	Buick	6.02
29—W. L. Brown (non-contestant)	Interstate	....
30—T. E. Lawless (winner)	Maxwell	6.06 3-4
31—Mrs. Susan Millan	Packard	5.43 1-2
32—H. H. Baker	Pullman	5.21
33—Dr. Albert Fisher	Selden	5.54
47—C. A. Benjamin (non-contestant)	Packard	5.21
48—H. F. Smith	Franklin	6.33 1-2
49—N. C. Hyde (non-contestant)	Chalmers-Detroit	5.40 1-2
50—F. Wilkinson (non-contestant)	Franklin	5.45 1-2

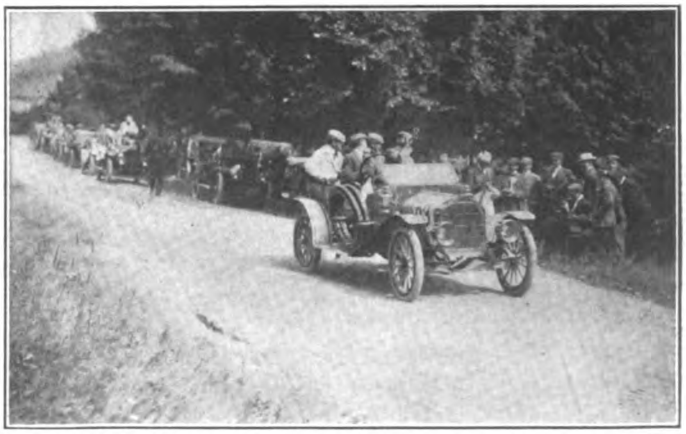
Bay State Notes of Automobile Interest

BOSTON, July 25—The Massachusetts Highway Commission is having completed this year about 50 miles additional of State highways that will fill in gaps here and there on through routes, and when the work is ended it will be possible to go from Boston to many large cities without leaving the State roads.

The South shore roads are getting much attention and very soon it will be possible to motor from Boston clear to the end of Cape Cod, returning by way of Buzzard's Bay, all on State roads, except where small villages are passed. The roads running through the center of the State are now nearly finished, while the northerly ones touching New Hampshire have been completed for some time. New Hampshire has made much progress with her State highways that come down to meet the Massachusetts roads. And Maine has taken up the work and appropriated a large sum to construct a decent road from the New Hampshire line through to Portland. That particular road has always been dreaded by motorists who knew its conditions, and many of them went to New Hampshire rather than go over it to Maine. These improvements will make motoring more of a pleasure to New Englanders and attract many visitors as well.

The Easton Machine Company has taken the salesrooms made vacant on Hereford street, Boston, by the retirement of the Hol-Tan company, as headquarters for the Morse car, made at Easton, Mass.

The Boston branch of the Winton company will be moved in December from the present quarters on Berkley street to a new building being erected on Commonwealth avenue in the vicinity of of the Packard, Buick, Peerless and Studebaker buildings. The new building will hold three motor companies, and C. F. Whitney with the Stoddard-Dayton and Alco cars will be another occupant. The Winton will occupy the center of the building.



First car in Watson-Cup contest returning to Syracuse

Brighton Beach Matinee Brings

BETWEEN 12,000 and 15,000 automobile enthusiasts paid admission Saturday to witness the program of nine races staged at Brighton Beach by the Motor Racing Association. The card was attractive and well filled, and there was enough incident and excitement during the afternoon to hold the interest of the spectators.

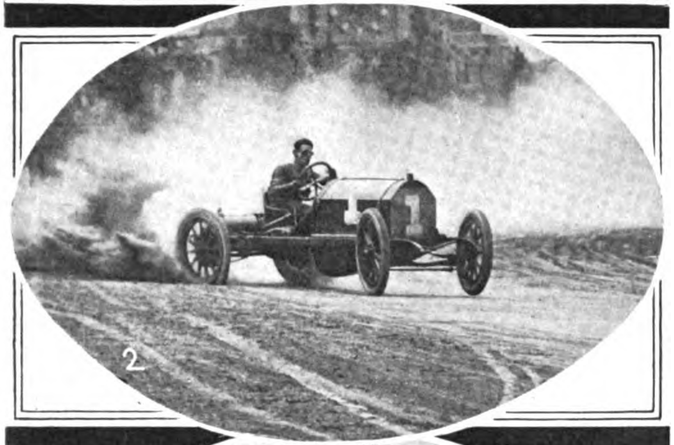
Caleb S. Bragg, in the amateur handicap event, proved the star of the matinee. Starting from scratch he pushed his big special Fiat along at a hair-raising speed and was picking up his field with ease when in making the turn into the stretch during the third circuit his car skidded and before he could regain control the radiator was butted through the infield fence. The driver kept his head and making a quick turn shot through the fence at a different point, took up the chase once more and managed to get to the wire ahead of his field by about 50 yards.

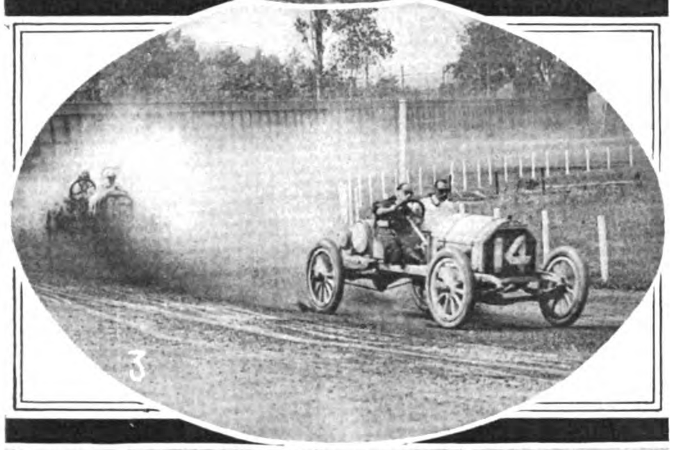
The duel between the Simplex "90" and the Fiat "60," run in two heats, the first of five miles and the second in two miles, resulted in a victory for the former. In the first heat the Fiat led for three miles, when the Simplex, moving fast in the stretches and hanging close on the turns, caught and passed its rival, winning very easily in 4:41 3-5. As an indication of the margin the Simplex had in the final mile, it may be cited that the time of the fifth mile was 10 seconds slower than that made in either the third or fourth circuits. In the second heat the Fiat broke first and led for a mile and a quarter, when the Simplex collared its rival and came on to win by three lengths in 1:49 4-5, last mile in 51 4-5, a new mark for the track.

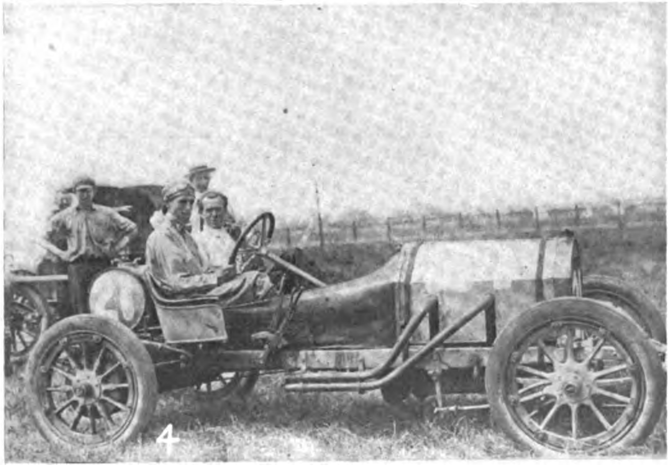
Tire trouble was plentiful in the match race and in several of the other events on account of a sharp edge at the head of the stretch, where the turn had been cemented and the cars were obliged to plunge off the cement at an angle that proved trying to the tires. There was an agreement in the match race that in case of tire trouble in any heat the heat might be run over. Both contestants were obliged to take advantage of the rule and the Simplex finished the first heat on flat tires.

The hour race was well filled and its running was sharply contested. The carded field consisted of eight machines, and while S. P. O. No. 17, which broke its steering knuckle in its class race, and the Buick No. 16, winner of its class race, were withdrawn their places were taken by the Croxton-Keeton and the Palmer-Singer. The Simplex "50" got away with the gun, trailed by the Palmer-Singer and No. 20, S. P. O. The rest of the field was close up, the tailender being the Croxton-Keeton, which took a position on the rail and plugged steadily along during the whole hour, going faster at the end than at the beginning. The Marion and the Cole "30" also trailed the early pace.

When the cars had settled down to hard work the Simplex was in front with the No. 20 S. P. O. second and the Palmer-Singer third. This order was maintained to the twentieth mile, when the S. P. O. was driven up to the pacemaker and in a fierce struggle managed to lead the Simplex down the length of the back stretch. There the S. P. O. had enough and after trailing for a few circuits limped around to the stable turn, where adjustments were made. During this process the car was lapped a couple of times and the Palmer-Singer succeeded to second place. The Marion came along steadily between this point in the race and the thirty-third mile and was lying in fourth position when the Simplex threw a tire, leaving the Palmer-Singer out in front with the Marion in second position. By the time the Simplex returned the Palmer-Singer was a mile and a half in front and it held the lead until the fortieth mile post, when it was taken to the pits for new tires. In the meantime the Simplex, coming with a whoop, assumed the lead again and held it to the end, winning by a fraction of a lap from the Marion, which appeared to be gaining slightly upon the winner. The Palmer-Singer despite its hard luck was third, while the Cole was fourth







1—Start of Event 7, in which the Fiat beat the Simplex

2—De Palma's Fiat throwing a tire at head of the stretch

3—Lorimer's Chalmers leading the Beardsley Buick in Event 5

4—Louis Disbrow and the Marion, mile trophy winners

Great Enjoyment and Success

and the Croxton-Keeton fifth. S. P. O. No. 20 was sixth and made the last mile two seconds faster than the winner. The Houpt-Rockwell was on three cylinders for 10 miles of the 43 it covered and the S. P. O. 23 retired with a score of only 18 miles.

The first event was between two Hupmobiles and was won by No. 7. The farther the cars went the greater was the lead of the winner. The final margin was over half a mile. The second was between a Cole "30" and a Patterson. The latter led most of the way to the tenth mile, where the Cole galloped away, winning by the length of the stretch.

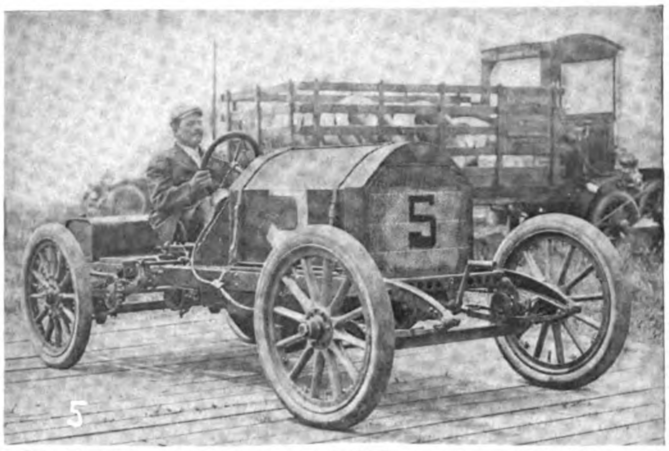
The fourth found a field of five, including three S. P. O. cars entered by different owners, a Marion and a Correja. The Marion won a beautiful race from S. P. O. No. 23 and S. P. O. No. 20. It was in this race that S. P. O. No. 17 broke its steering knuckle. Correja was on three cylinders most of the way.

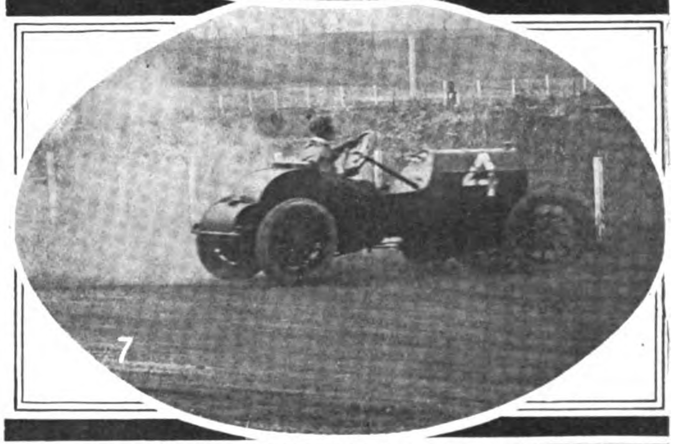
No. 16 Buick won the fifth event in a sharp drive all the way from the Chalmers entry. The Midland narrowly escaped accident, striking the fence at the head of the stretch, but continued to the finish. The seventh was captured by the Fiat "60," which took a winning lead after the fourth mile. The Simplex "50" was second and the Knox third with a quarter of a mile interval separating them. The Knox suffered severely from tire troubles and finished on two flat tires.

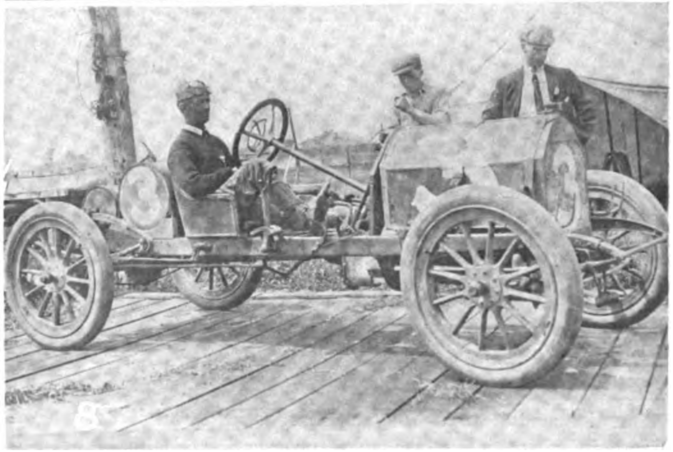
The Fiat No. 4 won the free-for-all with ease. The Knox was second and the Midland took the small end of the purse. Buick No. 16 appeared a certain contender for second honors until the eighth mile, when it retired. The Hupmobile completed eight circuits and The Only Car made two less.

A. B. Cordner was chairman of the racing committee and H. M. Swetland presided as referee. The summary:

Event 1, Class C, Division 1C—Awards: $100 to winner, $50 to second; ten miles—				
No.	**Car**	**Entrant**	**Driver**	**Time**
7	Hupmobile	C. B. Derby	C. B. Derby	13:35 3-5
8	Hupmobile	H. J. Koehler	A. C. Dam	14:26 3-5
Event 2, Class C, Division 2C—$100 first, $50 second; ten miles—				
3	Cole "30"	Colt-Stratton Co.	"Bill" Endicott	12:32 3-5
6	Patterson	W. P. Mallon	H. A. Neeley	12:44 3-5
Event 3, Special Match Race—Purse $500; first heat five miles; second, two miles—				
5	Simplex "90"	Simplex Auto Co.	Robertson	4:41 3-5
1	Fiat "60"	Fiat Auto Co.	De Palma	
Second heat—				
5	Simplex "90"	Simplex Auto Co.	Robertson	1:49 4-5
1	Fiat "60"	Fiat Auto Co.	De Palma	1:50 3-5
Event 4—Class C, Division 3C—$100 and Milo trophy, first; $50 second; ten miles—				
21	Marion	C. E. Reiss	L. A. Disbrow	10:55 2-5
23	S. P. O.	S. E. Wishart	S. E. Wishart	11:11
20	S. P. O.	H. S. Lake	J. Juhasz	11:52
Event 5, Class C, Division 4C—Ten miles; first $100, second $50—				
16	Buick	R. E. Beardsley	R. E. Beardsley	10:05 2-5
14	Chalmers	C. H. Page Co.	L. Lorimore	10:09 3-5
19	Midland	J. M. Boyle	Leo Anderson	10:40
Event 6—Five miles, amateurs; trophies for first and second; handicap—				
4	Fiat (scratch)	C. S. Bragg	C. S. Bragg	4:46 1-5
24	Simplex (15)	James Doig	Doig	5:09 2-5
16	Buick (20)	R. E. Beardsley	Beardsley	
23	S. P. O. (30)	S. E. Wishart	Wishart	
25	White St. (55)	E. A. Bofinger	Bofinger	
Event 7, Class C, Division 5C—First $100, second $50; ten miles—				
1	Fiat	Fiat Auto Co.	De Palma	10:00 2-5
9	Simplex "50"	Simplex Auto Co.	Robertson	10:10
2	Knox Giantess	Mrs. J. N. Cuneo	L. A. Disbrow	
18	Palmer-Singer	P.-S. Mfg. Co.	Harry Cobe	
8	Houpt-Rockwell	H. S. Houpt Mfg. Co.	S. Martin	
Event 8—Free-for-all—$200 first, $100 second, $50 third; ten miles—				
4	Fiat	C. S. Bragg	C. S. Bragg	10:09 1-5
2	Knox	Mrs. J. N. Cuneo	Disbrow	10:30
19	Midland	J. M. Boyle	L. Anderson	10:38 2-5
16	Buick	R. E. Beardsley	Beardsley	No fin.
8	Hupmobile	H. J. Koehler	A. C. Dam	No fin.
26	The Only Car	W. D. Gloat	Gloat	No fin.
Event 9—Hour race; $300 first, $150 second, $75 third, $25 fourth; and $200 gold watch to winner—				miles
9	Simplex	Simplex Auto Co.	Robertson	53 1-2
21	Marion	C. A. Reiss	Disbrow	53 1-4
18	Palmer-Singer	P.-S. Mfg Co.	Cobe	52
3	Cole "30"	Colt-Stratton Co.	Endicott	51
12	Croxton-Keeton	C.-K. Company	W. C. Spenney	49
20	S. P. O.	H. S. Lake	J. Juhasz	48
8	Houpt-Rockwell	H. S Houpt Mfg. Co.	S. Martin	43







5—G. E. Franquist, designer of Simplex 90 that won Event 3

6—Robertson, the Simplex driver, winning the hour race

7—Bragg going through the fence in the 10-mile free-for-all

8—"Bill" Endicott, who handled the Cole very cleverly

Detroit Hears of Electric Truck Plant's Coming

DETROIT, July 25—One of the most important expansions with which the local automobile industry has been identified in some time is foreshadowed by the announcement of President Walter E. Flanders, of the E-M-F Company, that the electric commercial vehicle plant of the Studebaker Manufacturing Company will be moved to this city from South Bend.

Immediately after the reorganization of the Studebaker-E-M-F companies, Mr. Flanders set about securing the consent of his associates to a centralization of manufacturing interests. The first step in this direction will be the establishment here of an electric commercial vehicle plant on an immense scale.

When the E-M-F Company took over the old DeLuxe plant and rebuilt it throughout as a home for the Flanders "20" most of the vacant property to the north was purchased, ostensibly for further expansion of the Flanders and constituent plants. Now plans have been prepared for factory buildings to house the newest addition to the local industry.

All that remains to be cleared up is the question of constructing a tunnel under the railroad lines dividing the property, through which to transmit power. When this is out of the way actual construction will be undertaken without delay, and it is stated that when completed the new plant will give employment to 2,000 skilled mechanics. This will make the fourth immense plant for the Studebaker-E-M-F interests in Detroit, the others being the E-M-F "30" plant on Piquette avenue, where new buildings are in process of construction; the Flanders "20" plant on Clark avenue, and a big factory on Franklin street. In addition there is a body factory at Pontiac and a large plant at Port Huron where rear axles for the "30" are manufactured.

This move puts an effectual quietus on unfounded rumors which have been circulated that Mr. Flanders contemplated resigning his present position and identifying himself with a new company. Mr. Flanders has strenuously denied this report, declaring himself satisfied where he is.

According to the State highway commissioner, Wayne County, in which Detroit is situated, has the finest roads of any county in the State. To those who have toured Michigan in unfavorable weather this may not seem like an achievement of which to boast; but the fact remains that within a short time all the principal thoroughfares leading out of Detroit will be in first-class condition, thanks to the activity of the county road commissioners. The paving of Woodward avenue has been completed to the county line, and Michigan, Gratiot and Grand River avenues, familiar to motorists the country over, are being improved as rapidly as possible. The Detroit Board of Commerce has taken the initiative in a move to secure a bond issue of $2,000,000 for good roads, and as an object lesson to unbelievers and to satisfy themselves about 100 members of that body indulged in a tour of inspection Thursday. What they discovered was plenty, and their findings will be incorporated in a report to be presented to the supervisors at an early date.

The resignation of Ernest Moross as general manager of the Indianapolis speedway has served to revive talk about a speedway for Detroit, on which Moross has long been figuring. Two or three sites have been under consideration for some time, and all that is necessary to make the undertaking assume tangible form is the financial backing. Whether that will be forthcoming remains to be seen, as in spite of the lead they hold in the matter of production Detroit makers have never been particularly partial to the racing game.

The Chalmers Motor Company has decided to withdraw from racing, in which it has been so successful, and the Hudson is counted among the new entrants.

Anent auto racing, the coming auto exhibit at the Michigan State Fair grounds will be further enlivened by races on Saturday of fair week, September 24. It is expected that the track, which is very fast, will be the scene of some good sport.

To accommodate employees in the new plant it will erect for the manufacture of Hewitt trucks in the northern part of the city, the Metzger Motor Car Company is preparing to build on a private right-of-way a half mile of street railway, running from Hamilton boulevard west to Twelfth street. The line will also connect with an extension of the Woodward avenue car tracks. Ground will soon be broken for the first of the buildings, which, it is expected, will eventually cover the entire 40 acres holdings of the Metzger company at this point.

Local automobile men are feeling the effects of the Grand Trunk Railroad strike in no uncertain manner, owing to the curtailment of accustomed shipping facilities in this quarter. Several of the larger plants are located on the Grand Trunk line, and the suspension of freight operations is alike hindering the receipt of cars for outbound shipments and the arrival of materials from outside points. Railroad officials give the assurance that the trouble will be brief and the fact that freight is beginning slowly to move bears out this statement.

The Charles H. Fuller Company has opened advertising offices in Detroit, with Martin V. Kelley and F. M. Randall in charge. Mr. Kelley recently disposed of his half interest in the McManus-Kelley Company, which removed to Detroit a short time ago, and F. M. Randall was associated with the Lord & Thomas Company up to the time of making this change.

What promises to be Detroit's biggest automobile show is scheduled for State fair week, September 19-24, when the motor interests will be found housed in a handsome new building, 125 by 275 feet, of two floors and affording ideal lighting conditions for show purposes.

There was a space drawing recently, and the entire ground floor went like hot cakes, being subscribed for in 30 minutes. Nearly every car handled in Detroit will be represented and the accessory firms are also showing interest in the display.

According to announcement, no expense will be spared to give the motor companies a suitable place to display their products. The new building will cost $40,000.

Progress is being made toward the completion of the various new motor car factories that have been in course of erection for the past two months or more, and early fall will see practically all of them in operation and working full capacity. Out in the Fairview district the new buildings of the Anderson Forge & Machine Company and the Hudson Motor Car Company, diagonally across from the Chalmers industrial group, are rapidly taking shape and have put an entirely different complexion on a district which, up to a few months ago, was nothing more than pasture land.

The Van Dyke Motor Company's new factory, 60 by 512 feet, at Campbell avenue and Leavitt street, has started operations and the first few of the 1,400 machines contracted for up to July 1 have been turned out. The plant has a capacity of 5,000 cars per year and for the present will give employment to 300 men. The new plant of the Grabowsky Power Wagon Company at Mount Elliott avenue and the Michigan Central Railroad, is almost ready for occupancy. Transportation facilities are such that 20 cars may be loaded at one time.

The Detroit United Railway moved into its new Woodward avenue barns in Highland Park last week and the Cadillac Motor Car Company immediately took possession of the old barns at Woodward avenue and Amsterdam street.

Announcement is made that the Small Motor Car Company is to be incorporated shortly with a capital of $200,000 for the manufacture of an underslung runabout car with a 25-horsepower engine of unit power plant construction. The bearing and cooling systems will be specially featured. The car will have a 100-inch wheelbase, 34-inch wheels and will weigh 1,400 pounds fully equipped. It is planned to manufacture the car in Detroit and Winnipeg.

Putting the Automobile House in Order

By COKER F. CLARKSON, General Manager Society of Automobile Engineers

A BIG task in automobile engineering lies right at hand. President Coffin, of the S. A. E., long ago suggested the adoption of definite terms for the multitudinous parts of the automobile, the component elements of which are denominated by various titles. This reform never came to fruition with the Licensed Association, having been sidetracked for other matters temporarily more important. The Society of Automobile Engineers is now entering upon this work.

Standardization is simply a matter of common sense, an absolute essential in bringing any important industry to its proper basis of efficiency in both production and replacement. Its accomplishment in its proper function can be brought about only by the utmost care on the part of those competent to pass on the particular matter in hand. The attention of the competent men must be had; and these men are abnormally busy in their routine duties. Much correspondence, detail work, discussion in committee and full meetings are necessary. Frequently a large amount of experimental data must be considered; often special tests must be made. But if the work be not done, confusion will become chaos. This is the history of every industry in which mechanical, as well as other, engineering is involved. The positive benefits of standards have been most clearly proved, as well as the many forms of vexation resulting from their nonexistence.

There are thousands of parts in any automobile. All makers of automobiles buy raw material which they form and machine into finished product. Their engineering departments must first specify more or less minutely the chemical composition or the physical characteristics required in each case before turning over orders to the purchasing departments. This specifying of the chemical properties or physical qualities is very largely a matter of standardization. For a proper working basis, it is necessary that the use of standard terms be established, bringing celerity and exactitude in specification. The engineering departments must specify dimensions of materials ordered. For this, standard reference tables, prepared in view of all the reasonable demands of design and of the inexorable facts surrounding sufficiently fast production of raw materials or parts, must be at hand. The point is that if the number of sizes of a given article be standardized down to a list representing the reasonable demands of the case, the article can be made better, more cheaply and more quickly, and therefore be delivered sooner. Anyone familiar with the workings of an automobile factory knows of the delays and complications attendant upon production. All of the material and parts producers say the same thing: "If you automobile makers jointly require us to fill orders in which a lot, sometimes many hundreds, even thousands, of sizes are specified, you must pay more for the goods and wait longer for them. Difference in size means new setting of machinery and change of tools. Variety of production strongly tends to reduce excellence of product. If you specify unreasonable or unnecessary sizes, you are only standing in your own light." This applies to all the materials of which an automobile is made, and to the tools with which it is made.

Sentinel Trophy Won by Buick Car

MILWAUKEE, WIS., July 25—Going through a hard six-day run, the brake, clutch and motor tests and a rigid final technical examination without a demerit, a Model 19 Buick, entered by the Hokanson Automobile Company of Madison, Wis., and driven by Emil Hokanson, won the $1,000 *Milwaukee Sentinel* trophy, the first prize in the Wisconsin State Automobile Association's first annual reliability tour. The Pope-Hartford T model, entered and driven by Emil Estberg, of Milwaukee, was awarded second place, with a total penalty of three points. The Model G Franklin, nominated by the Franklin Auto & Supply Company, of Milwaukee, and driven by L. M. Springer, was third, with six demerits. The summary:

No.	Car	Model	Entrant	Driver	Total Penalty
8	Buick	19	Hokanson Auto Co.	Emil Hokanson	0
17	Pope-Hartf'd	T	Emil Estberg	Emil Estberg	3
21	Franklin	G	Franklin Auto and Supply Co.	L. M. Springer	6
20	Ford	T	Hickman - Lauson-Diener Co.	W. H. Diener	9
9	Buick	17	Buick Motor Co. (Wis. Branch)	Wm. Fisher	14
2	Rambler	53	Rambler Garage Co. of Milwaukee	Art Gardiner	16
22	Overland	42	Bates - Odenbrett Auto Co.	John Heber	16
18	Reo	S	Curtis Auto Co.	A. C. Thomas	19
7	Jackson	59	W. L. McEldowney	W. L. McEldowney	26
11	KisselKar	D-10	KisselKar Co.	W. C. Rice	34
10	KisselKar	D-10	KisselKar Co.	W. R. Rice	35
24	Petrel	F	Petrel M. Car Co.	G. D. Waite	38
12	KisselKar	LD-10	Johnson Service Co.	J. Marsden	42
15	Johnson	10-Spl	KisselKar Co.	Arthur Ove	52
14	Pierce-Rac'e	K	Morrison M. Car Co.	Lewis Strang	53
5	Mitchell	T	Mitchell Auto Co.	F. P. Wilkins	57
19	Corbin	18	Curtis Auto Co.	Gordon Bird	111
4	Badger	B10	Badger M. Car Co.	C. Kobersteen	142
26	Marion	Bob-Cat	Geo. Browne	Geo. Browne	204
6	Cadillac	30	Jonas Auto Co.	Aug. A. Jonas	422
16	Ohio	40A	Case Plow Works	Ross Henwood	488
3	Badger	B10	Badger M. Car Co.	Dan Arbogast	648
23	Staver-Chi.	M	Stephenson M.C. Co.	H. Monckmeier	1000
	Withdrawn end of second day.				
1	Rambler '11	64	Rambler Garage Co.	Ted Collier	2813
	Withdrawn at end of run. No final examination.				

Thirty-two Start in Cleveland "News" Reliability

CLEVELAND, O., July 26—At six o'clock on the dot, Monday morning Starter George Collister sent away the first of the 32 contesting cars in the Cleveland *News* Reliability run, the biggest automobile event that Cleveland has ever seen.

Nearly every car of prominence that is handled in Cleveland was entered in the run. Prominent among the starters were the famous Thomas Flyer, the hero of the round-the-world New York to Paris contest, and the historic Oldsmobile Mudlark, which carried representatives of the Cleveland newspapers.

Of the 1911 cars entering the first run of their existence are the Owen, 50 horsepower model, made by Ralph Owen, of Cleveland and driven by F. Monroe, and the Palmer-Singer, driven by Hugh Miller, the Cleveland agent, a 6-cylinder, 40 horsepower machine. Following is a list of the starters:

Car	Entrant	Driver
Oldsmobile	Olds-Oakland Co.	C. H. Winters
Studebaker "40"	Studebaker Automobile Co.	W. D. Cousins
Palmer-Singer	Hugh Miller	Hugh Miller
Buick	Cleveland br. Buick Co.	....
E-M-F	L. J. Frisch	Frank Grace
Henry "35"	Jack Sperry	Jack Sperry
Regal	Regal Motor Sales Co.	J. C. Hipp
Hinescar	O. Alexander	O. Alexander
Gabriel	Gabriel Carriage Co.	A. S. Soper
Firestone-Columbus	Euclid Auto Co.	Harry McIntosh
Atlas	Euclid Auto Co.	Harry Kortz
Pierce-Racine	H. S. White & Co.	C. W. White
Hupmobile	J. M. Rauch	J. M. Rauch
Cutting "40"	Sterling Motor Sales Co.	J. C. Koepke
Maxwell	Maxwell-Briscoe Cl. Co.	Frank Santry
Brush	Maxwell-Briscoe Co.	D. E. McCoy
Columbia	Maxwell-Briscoe Co.	C. G. Bleasdale
Gaeth	Gaeth Auto Co.	Otto Linder
Krit	Gabriel Auto Co.	Harry Gabriel
Owen	H. R. Hoffman	Ralph Owen
National	D. E. Foote	D. E. Foote
Garford Truck	Garford Motor Truck Co.	Ralph Kinney
De Tamble	Kraus Motor Sales Co.	H. W. Orndorfer
Hudson	Hudson Motor Car Co.	Wm. McCalla
Packard	Thomas Swan	Thomas Swan
Hinescar	Woodland Motor Car Co.	F. J. Moore
Norwalk "35"	Norwalk Motor Car Co.	H. B. Olds
Oakland	Olds-Oakland Co.	Fred Krune
Stoddard-Dayton	Harry S. Moore	H. S. Moore
Overland	H. C. Knudsen	H. C. Knudsen
Chalmers-Detroit	John Stambaugh	John Stambaugh

Contest Board Declares Premier Gliddenites Are Not Stock

LIKE a bolt from the blue came the news last week that the Contest Board of the A. A. A. had reversed the ruling of the referee in the Glidden tour of 1910 and had disqualified the two Premier cars that finished in the Glidden Trophy class. One of these cars had apparently won the prize. The ruling was based upon the protest of the Chalmers Motor Company that the auxiliary oil tanks and pump equipments used by the protested cars were not stock equipment according to catalogue.

The significance of the ruling is that the Chalmers entry for the Glidden Trophy is placed first and is awarded the prize. The meeting was presided over by S. M. Butler and the text of the ruling was as follows:

> "The appeal of the Chalmers Motor Company is sustained. There was no evidence adduced before the Contest Board on this appeal or before the referee or at the time the Premier entries were made or at the start of the 1910 Glidden tour to prove that the auxiliary oil tank and pump equipment was stock equipment. The Contest Board finds that this auxiliary oil tank and pump equipment was not stock equipment under the rules.
>
> "The Premier Motor Manufacturing Company fails to comply with Rule 6 of the 1910 contest rules in not furnishing, to the technical committee of the American Automobile Association, after repeated demands, from June 29 to July 21, 1910, during which period three of its members visited the Premier factory, evidence sufficient to establish the stock status of Premier cars numbers 1 and 2 entered in the 1910 national reliability tour of the American Automobile Association in respect to equipment of auxiliary oil tank and pump for injecting oil direct to the crank case.
>
> "The decision of the referee is reversed and Premier cars numbers 1 and 2 are disqualified, and the Glidden Trophy awarded to the Chalmers Motor Company's entry No. 5."

Harold O. Smith, president of the Premier Motor Manufacturing Company, secured a preliminary order of injunction from Supreme Justice Kelly of New York against the Contest Board of the A. A. A., forbidding that body to make delivery of the Glidden Trophy to the Chalmers Motor Company.

The complaint filed on behalf of President Smith alleges that the action of the Contest Board in disqualifying the Premier entries is without jurisdiction, wrongful, illegal and a violation of the rules governing the contest.

H. O. Smith was represented in the Court proceedings by Sidney S. Gorham, of Chicago, and George C. Lay, of New York.

In commenting upon the situation, Mr. Smith said: "I have decided to test in the courts the validity of the action of the Contest Board of the American Automobile Association in reversing the decision of Referee Whiting in awarding the Glidden Trophy to me as the entrant of the Premier car No. 1, after having passed upon the protests filed with him."

At a meeting of the Contest Board of the American Automobile Association on Wednesday H. O. Smith and the Premier Motor Manufacturing Company were disqualified and rendered ineligible for competition in all contests here under the sanction of the Contest Board of the A. A. A. until further notice.

Automobile Notes from Quaker City

PHILADELPHIA, July 25—Entry blanks for the third Fairmount Park 200-mile stock chassis road race, which is now recognized as the chief motoring feature of Philadelphia, and which is rapidly attaining the distinction of being one of the chief events in the country, have been issued and as there is assurance of many notable drivers and machines, there is no doubt about its success.

The Quaker City Automobile Club will co-operate with the Philadelphia municipal authorities in conducting it. The contest this year will take place on Saturday, October 8, at 12 o'clock noon. R. E. Ross, who acted in a similar capacity last year, will be the referee, with G. Hilton Gantert and Joseph L. Kier starters. The following conditions and details of classification are announced in the entry blanks:

The race is open to any chassis of gasoline car which is in accordance with definition of "stock chassis" and to be governed by the following table of piston displacement and minimum chassis weights:

Division	Piston displacement in cubic inches	Minimum weight in pounds
4-B	301 to 450	2000
5-B	451 to 600	2300
6-B	601 to 750	2500

No car to compete in any class above that to which its weight entitles it. No dead weight of any character or description to be added or attached in any manner to a car as ballast. Entrance fee, $500.

Four prizes are offered for the best time for the 200 miles—first, $2,500; second, $1,250; third, $750, and fourth, $500; while at the same time there will be additional prizes for cars in each of the respective divisions.

The Philadelphia *North American* commercial vehicle reliability run from Philadelphia to Atlantic City and return August 12 and 13 is unique in that it will be the first of its kind ever held. The 26 entries in the various classes are divided as follows: Manufacturers' Division—Class A—1 1-2 tons capacity and less. Class B—Between 3001 and 5999 pounds. Class C—Three tons and over. Private Owners' Division—Class A—1 1-2 tons capacity and under. Class C—3 tons and over.

Buicks Outclass Fields at Fort Erie Meeting

BUFFALO, July 25—Racing for two days at the Fort Erie track under the auspices of the Automobile Trade Association ended Saturday. Over 5,000 attended the final meeting.

The track was the regulation flat oval, and the competitors in the various events were hidden for part of the distance under a pall of dust. The smallness of the fields alone made it possible to try for any speed. The events generally had only two or three entrants, which robbed them of the spectacular features of large and hotly contested races. The Buick entries outclassed their rivals so as to render the majority of the events one-sided.

The Buick team had practically their own way in the majority of the contests. The summary:

FRIDAY'S EVENTS

Five miles, stock chassis, 160 cubic inches or under—

Car	Driver	Time
Herreshoff	Ned McCormick	6:14 2-5
Herreshoff	Walter Emmons	6:21 3-4
Five miles, stock chassis, 231 to 300 cubic inches—		
Buick	Louis Chevrolet	6:10
Maxwell	Ed Crane	6:22
Five miles, stock chassis, 301 to 450 cubic inches—		
Buick	Louis Chevrolet	5:45
Pullman	H. Hardesty	6:09
Maxwell	Ed Crane	6:14
Ten miles, stock chassis, 451 to 600 cubic inches—		
Buick	Louis Chevrolet	10:59
Buick	Arthur Chevrolet	11:20
Thomas	Ed Crane	11:30
Five miles, free-for-all, handicap—		
Maxwell	Ed Crane	5:15 2-5
Herreshoff	Ned McCormick	5:30
Buick	Arthur Chevrolet	5:37
Pullman	H. Hardesty	5:42
Herreshoff	Walter Emmons	6:11

Five miles, free-for-all—

Car	Driver	Time
Buick Special 60	Louis Chevrolet	4:59 2-5
Buick	Arthur Chevrolet	5:47
Thomas	Ed Crane	6:12

SATURDAY'S EVENTS

Five miles, stock chassis, 160 cubic inches or under—

Car	Driver	Position	Time
Herreshoff	Ned McCormick	Won	6:39
Herreshoff	Walter Emmons	2	7:42
Five miles, stock chassis, 161 to 230 cubic inches—			
Buick	Louis Chevrolet	Won	6:11 4-5
Maxwell	Ed Crane	2	6:15
Five miles, stock chassis, 231 to 300 cubic inches—			
Buick	Louis Chevrolet	Won	5:35
Pullman	H. Hardesty	2	5:50
Maxwell	Ed Crane	3	6:19
Five miles, stock chassis, 301 to 400 cubic inches—			
Buick	Arthur Chevrolet	Won	6:20 3-4
Buick	Louis Chevrolet	2	6:55
One mile exhibition—			
Buick Special 60	Louis Chevrolet		:55 2-5
Ten miles, stock chassis, 451 to 600 cubic inches—			
Buick	Louis Chevrolet	Won	11:50 2-5
Buick	Arthur Chevrolet	2	12:65
Five miles, stock chassis, $1,201 to $1,650—			
Pullman	H. Hardesty	Won	5:09 4-5
Herreshoff	Ned McCormick	2	6:11
Herreshoff	Emmons	3	6:17
Herreshoff	Smith	4	6:52
Maxwell	Ed Crane	5	6:54
Free-for-all, five miles—			
Buick	Louis Chevrolet	Won	5:08
Buick	Arthur Chevrolet	2	5:55
Five miles, free-for-all, handicap—			
Herreshoff	Ned McCormick	Won	5:18
Pullman	H. Hardesty	2	5:27
Buick	Louis Chevrolet	3	5:47
Herreshoff	Emmons	4	6:17
Maxwell	Ed Crane	5	6:25
Buick	Arthur Chevrolet	6	6:33

Minneapolis State Run Has Eighteen Entries

MINNEAPOLIS, July 25—The second annual reliability run held under the auspices of the Minnesota State Automobile Association started from the St. Paul Hotel at 7.30 o'clock Friday morning, to cover 658.2 miles of fine roads to Sioux Falls and back to Minneapolis. Dr. C. E. Dutton refereed the event to Sioux Falls.

The final entry list showed 18 cars contesting and six making the run as non-contestants. The pilot car left the St. Paul Hotel at 6.15 a. m. Reuben Warner, Jr., president of the Minnesota Automobile Association, in a Pierce-Arrow car driven by Julius Huckow, was the first to follow the pilot. He started at 7.30. After him trailed the 16 other contestants and the six non-contestants, press machines, pilot car, pacemaker and two others who did not signify their intention of starting in time to be classified.

The list of entries follows:

No.	Car	Owner	Driver
1	Pierce-Arrow	Reuben Warner, Jr.	Julius Huckow
2	Stearns	Stearns Auto Co.	J. C. Littlewood
3	Hupmobile	Electric Vehicle Co.	Fred Starr
4	Reo	Fawkes Auto Co.	C. A. Lewis
5	Staver	Heaney Auto Co.	Floyd Duis
6	Halladay	Heaney Auto Co.	O. A. Talmland
7	Cadillac	Rudstenstad	W. Rudstenstad
8	Auburn	Ranger Auto Co.	W. Y. Ranger
9	Regal	Haynes Auto Co.	Arthur La Roche
10	Cole "30"	Cole Auto Co.	T. J. Seifert
11	Cole "30"	Cole Auto Co.	W. A. Alson
12	Ford	Northwest'n Auto Co.	A. A. Hanson
13	Franklin (n.-stop)	Western Auto Co.	A. W. Clark
14	Hudson	H. L. Smith	O. E. Martin
15	Ind. Auto Co.	Independent. Auto Co.	T. W. Shannon
16	Glide	G. L. Sylvester	C. E. Sylvester
17	Chalmers "30"	Brictson Mfg. Co.	C. J. Gilbert
19	Cartercar	Selcey Garage, St. Paul	

Six non-contestants were Apperson, pilot car; Corbin, pacemaker; Pierce-Arrow and Studebaker, press cars, and others.

The run for Friday was from St. Paul to Owatonna, 69.2 miles, and from Owatonna to Mankato, 93 miles, making the total run for the day 162.2 miles.

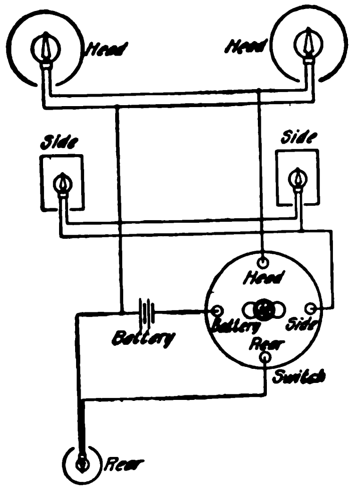
Accessories Occupy a Prominent Place

ELECTRIC LIGHT FOR GASOLINE CARS

THE adoption of electric lighting for gasoline cars is indicated by the safety of such a system, if for no other reason. Additional advantages to be claimed for it are, among others, "lighting up" from the driver's seat and un-blow-out-able lights. In the accompanying illustrations are shown several designs of lamps now being marketed by the National Electric Lamp Association, and a wiring diagram of a five-light system. Limousine lights and trouble lamps are also among the equipment furnished by the company. Although storage batteries furnish the most simple means of obtaining current, various generator systems have been introduced by the company for users who desire to enjoy the unstinted use of electric illumination.

Neat electric side lamp

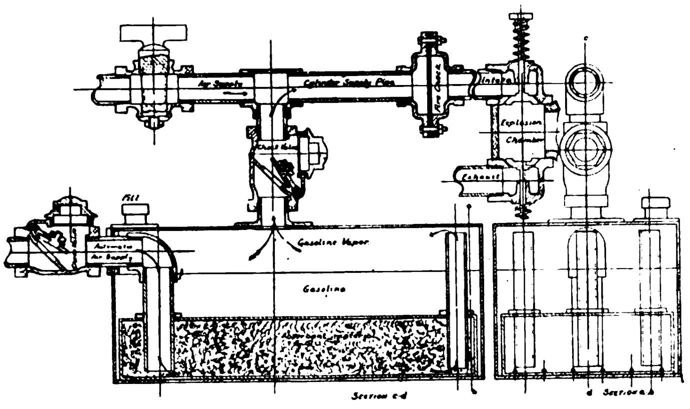


Five-light wiring system for automobile

A NEW FLOATLESS CARBURETER

WORKING without floats and having a carbureting chamber so arranged that it does not flood or become diminished with the variation of the fuel supply are among the advantages claimed for the Steward Carbureter, which is made by L. & J. A. Steward, of Rutland, Vt. The surface principle, which obtains in this device, allows of large pipes and a consequent ample supply of mixture at high speeds. In this carbureter the circulation increases the evaporative effect by allowing the saturated vapors to more rapidly mix with the less saturated; the globules of gasoline are allowed to settle out, and the mixture is "dry"; heat is kept more uniform throughout the apparatus and contents, and sudden demands for large quantities of gas are easily met.

Electric headlight, compact and sturdy



Sectional view of the Steward carbureter

TO BAR THIEVES AND MEDDLERS

PROTECTING one's car against the wiles of the thief and the foolishness of the meddler is an easy proposition, and not at all costly, with the Connecticut Automobile Lock, made by the Connecticut Tel. & Electric Company, of Meriden, Conn. All that is necessary for the driver, on leaving his car, is to apply the brake lever and place the lock in the adjacent notch of the segment on the release side of the same. On cars where the clutch is disengaged by the first movement of the lever before the brake is applied, the car can be locked without the brake being applied and with only the clutch disengaged, allowing of being moved about, as in a public garage. The lock is small enough to be easily carried in the vest pocket.

A HANDY POCKET REPAIR TUBE

A VEST-POCKET convenience like Gray's Handy Repair Tube, made by the Standard Leather Washer Manufacturing Company, 24-26 Boudinot St., Newark, N. J., should appeal to every motorist. It costs but a trifle, and contains tire chalk, tube of cement, patches, emery cloth and other tire-repair needfuls.

These outfits come in 7-inch tubes, each 1 1-4 inches diameter.

Another side lamp

A FENDER FOR CARS DE LUXE

The New Jersey Tube Company, of Newark, N. J., has designed the Conover Bumper, which would appear to be a policy of insurance against broken radiators, lamps, etc., not to mention lawsuits resulting from accidents.

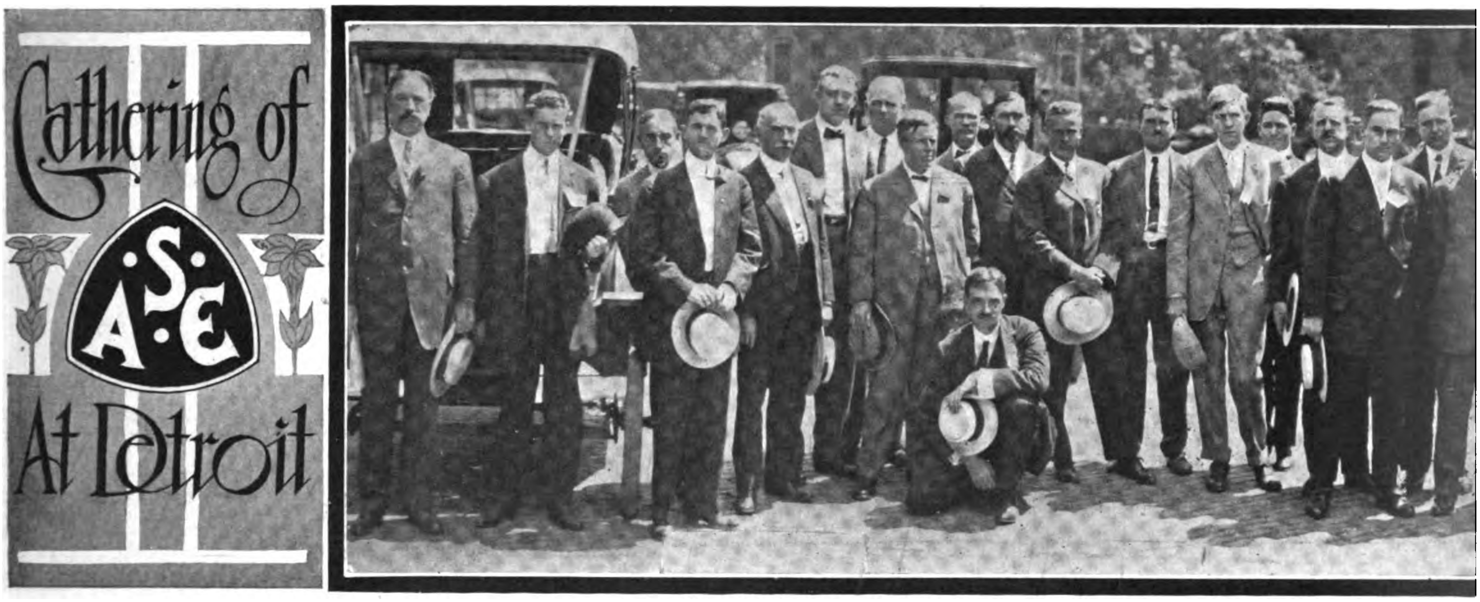
THE AUTOMOBILE

Detroit Extends Welcome to Largest S.A.E. Gathering

DETROIT, July 30—Five years of painstaking effort on the part of the automobile engineers of this country reached a fitting culmination at the Summer meeting which opened on July 28 with headquarters at the Hotel Tuller, and so largely attended that the accommodations of this establishment were far below the demand of the occasion, and many of the visiting engineers sought accommodations at the Pontchartrain, Cadillac, and elsewhere. It would be impossible to say just what the real attendance was. Of the membership proper, perhaps there were no more than 300 of them registered, but the new and aggressive policy of the Society, as laid down by President H. E. Coffin, which is being carried out to the letter by Manager Coker F. Clarkson, has attracted such wide notice that the engineers, who have not heretofore seen fit to ally themselves with the work, found it convenient to journey to Detroit and examine into the situation for themselves. Despite the care with which the programme was prepared, the entertainment committee, comprising President H. E. Coffin (ex officio), H. W. Alden, chairman; George W. Dunham, Russell Huff, H. M. Leland, F. E. Watts, E. T. Birdsall, A. P. Brush, F. H. Floyd, G. M. Holley, and G. E. Merryweather, found ample opportunity to tax its executive ability, which proved adequate for the needs, ending in the largest and most profitable meeting that was ever held by the Society.

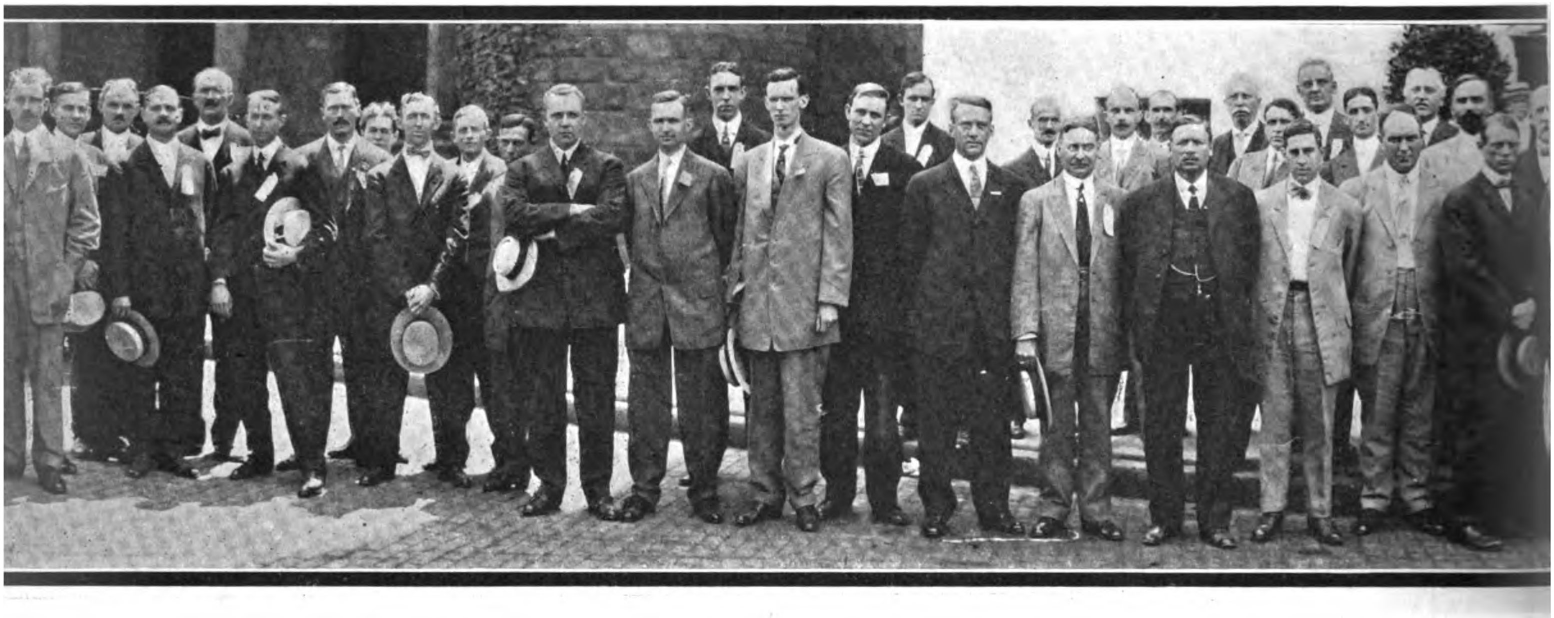


The programme was a large one, including ten set papers, covering extremely important subjects, all of which were read and discussed, excepting a paper in relation to a Franklin air-cooled motor test, which was deferred owing to the absence of Professor Rola C. Carpenter, the idea being to give to this paper the attention it deserves at the next annual meeting of the Society. The papers which were presented and discussed are printed in this issue of The Automobile in somewhat revised form. In addition to the set papers there were a series of discussions on various important phases of the automobile situation, but in addition to the formal discussion indulged in there were many informal talks and comparisons of notes that will go far to unravel the tangle that stands in the way of further refinement of the more advanced problems leading to finality in the automobile art.

Experience has shown that formal discussion of papers presented is very meagre, as a rule, and oftentimes the most pertinent points are brought out at informal gatherings of groups of the members after the meeting. As an illustration of this phase of the situation the matter referred to in the paper entitled "The Specification and Heat-treatment of Automobile Materials," by Henry Souther, will serve very well. In Mr. Souther's paper it was pointed out by him that a single type of steel, if heat-treated in view of the work to be done, might serve for all the purposes to which steel is put in the building of automobiles. Mr. Souther pointed out that the modulus of elasticity is scarcely different for the hardest alloy steel as compared with mild steel. He said that the only reason for using a higher type of steel than that presented in a Bessemer bar for crankshaft work is represented in the difference between the elastic limits of the respective products. Attention was called to ore from Cuba, that is said to be rich in nickel and chromium. Mr. Souther claimed that this ore carried about 1 per cent. nickel and about 4-10 of 1 per cent. chromium. Informal discussions involving this material brought out two or three points that will have to be reckoned with in the long run, among which is the fact that the

The crowd at the E-M-F factory

chromium content of this ore is apparently not relied upon as sufficiently near the point named to make it possible for fabricators of steel to claim that it would be a nickel-chrome steel product. It is even a question, according to some debaters, as to whether or not the nickel content is reasonably constant. Other engineers raised the question as to the efficacy of 1 per cent. nickel in steel, and some were quite positive in their declaration to the effect that 4-10 of 1 per cent. chromium is of small value, while one metallurgist pointed out that one of the big steel companies, in coping with this particular ore, "blew" the chromium because they had no use for it. There was one other point brought out by Mr. Souther which raised quite a little discussion, some of it formal, but for the most part in an informal way. It was claimed that open-hearth steel is relatively a poor product, and that it would be very capable were it to compare favorably with crucible steel. What Mr. Souther intended to convey apparently was the impression that crucible steel is a sort of "micrometer" to be used as a gauge or measure to go by in rating steel in general. Mr. Souther did not have the undivided support of the members present, and the metallurgists who were willing to express an opinion on the subject made it quite plain that a crucible pot cannot serve as an instrument of precision in gauging the quality of steel, due to the fact that good steel cannot be made by this process unless good raw materials are employed therein. It is generally admitted that the crucible process, despite its faults, is capable of great things, but there is no way known to the art by which the carbon of which the crucible is made can be kept out of the steel, nor is it possible to tell with accuracy how much of the carbon of which the pot is made will be absorbed in the steel. The average automobile engineer, in selecting crucible steel for his work, favors the contention that the carbon is likely to be relatively high, and regrets that he cannot be sure that it will be uniformly present. It is not believed that Mr. Souther carried conviction on this point. There is one other matter that came out in this particular paper that did not find favor. Mr. Souther said it was an old-fashioned idea to contend that in the process of cementation it was necessary to use low-carbon steel. He seemed to think that automobile engineers generally labored under the impression that 50 carbon steel could not be cemented. It was pointed out by some of the members present that there was nothing old-fashioned about the ideas of automobile engineers as they are constituted; they realize perfectly that carbon can be added by the cementing process even up to the point of saturation, and that if the steel, when it is subjected to the cementing process, is not up to the point of saturation more carbon will be taken up. The great question in automobile work is to pursue a safe plan, and safety lies in using a true grade of cementing steel in which the carbon content is below 16 points. Failure comes when the carbon in the core of the cemented section is relatively high, but no matter how low the carbon may be in the core, the shell will have the requisite quantity thereof as a result of cementing. It was the consensus of opinion of such of the members as favored discussion, that it is very necessary to standardize steel and to arrive at more definite conclusions, but they did not take kindly to the idea that it has to be crucible steel, or that heat-treatment will serve in the capacity of a cure-all in the absence of good steel.

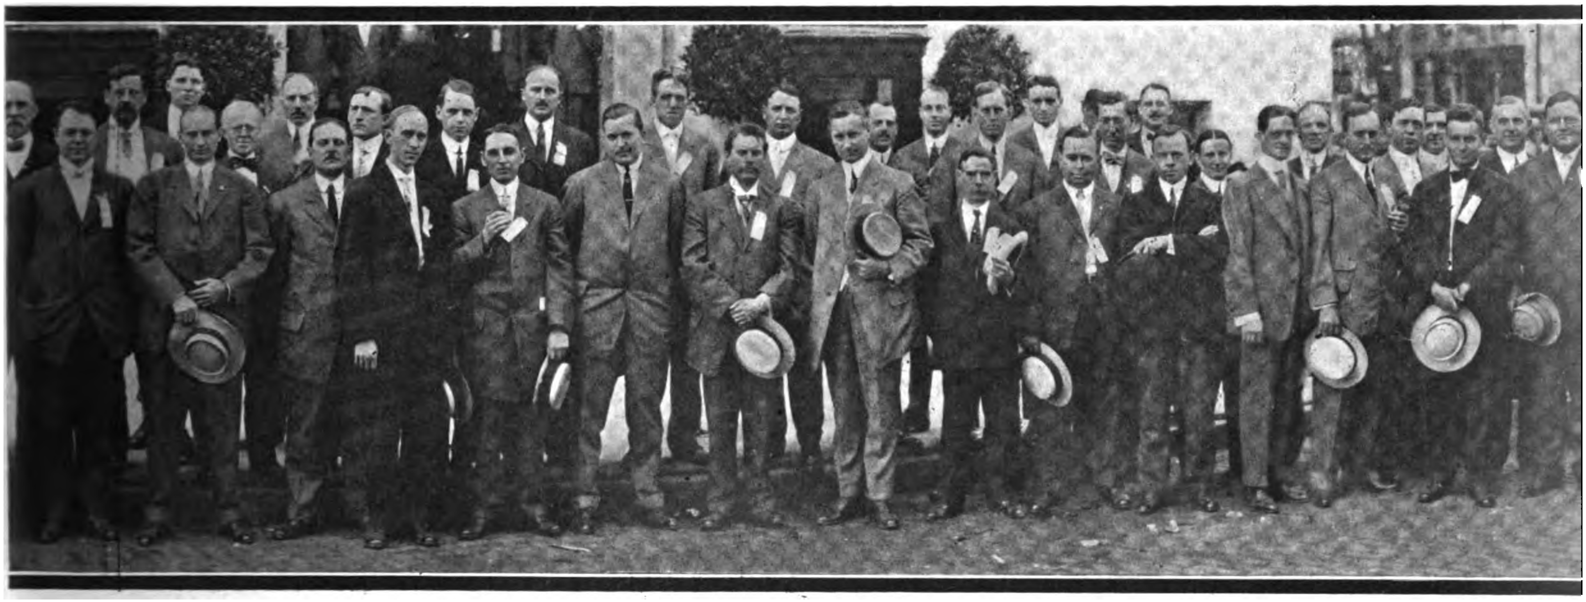


At the Timken-Detroit Axle Co.

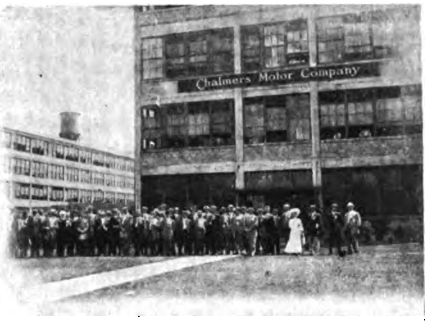
Testing the hardness of metals is a subject that attracted much notice, and was very aptly presented by F. A. Shore in his paper descriptive of the Scleroscope. The instrument in question has been quite considerably exploited in the literature of the subject for some little time, so that the main points in the discussion that took place

At Detroit Steel Products Co.

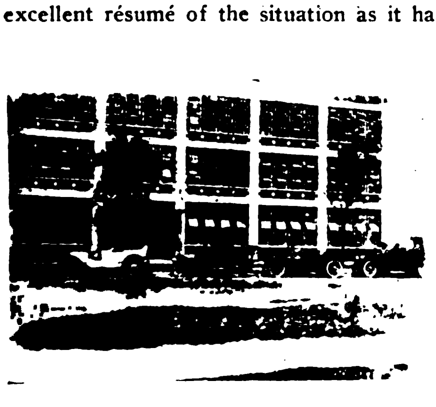
will be of more interest here than to present the paper in its entirety. Mr. Shore stated in his paper that the Brinell test is very limited in the conclusions that can be reached with safety. The falling tup hammer as used in the scleroscope is preferred by Mr. Shore, although he fails to explain how one would know the thickness of the shell of a cemented section by any reading that can be taken on this instrument, whereas in the Brinell test a small steel ball is pressed with sufficient force to indent the metal to whatever depth the operator desires, and among other information afforded thereby the thickness of the crust of the cemented section may be ascertained. Discussion brought out a rather peculiar situation which will require elucidation, it being the case, according to one member, that the readings for hardness are not the same when measurements are taken on balls of different sizes. It was stated that in a certain comparative test a ball 1 1-8 inches in diameter measured 100, whereas a ball of the same character of material and subjected to the same treatment measured 60, the only difference being that the latter ball was 1-2 inch in diameter. Against this situation stands the statement of another member who pointed out that the smaller the ball the less difficulty there will be in hardening it, but this statement does not jibe with the readings as above indicated, because the larger ball has the higher reading. It will be necessary to clear up such points as these before engineers will understand completely just what the scleroscope does indicate, although it was quite generally conceded that it has many nice uses in the plant, serving in the capacity of an instrument for quickly making comparative tests.



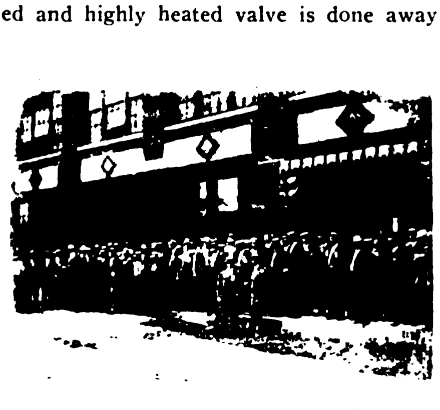
The paper by Eugene P. Batzell entitled "Slide, Rotary and Piston Valves Versus Poppet Valves for Gas Engine Service" was received with evident satisfaction, and it proved to be an excellent résumé of the situation as it has developed in automobile work, barring specific reference to the performance of the silent Knight type of motor, and the headway that was made in its exploitation. During discussion, David Ferguson pointed out that adverse criticism of the Knight sliding-sleeve scheme to be effective must overcome the force which is represented by the fact that the Knight type of motor is working extremely well, has proven to be of great advantage to the British Daimler Company and is being taken up by important Continental makers of automobiles, among which are the Panhard in France, Mercedes in Germany, Minerva in Belgium, and others. In response to a direct inquiry in relation to the performance of the Knight motor bearing upon the question of gas performance involving the mean effective pressure, Mr. Ferguson stated that the best indication of the advantage to be derived by water-jacketing the ports is shown by the high mean effective pressure realized, and that the thermal efficiency is high is proven by the fact that the radiator required in conjunction with the Knight motor is relatively small. Mr. H. G. Chatain pointed out that the thermal efficiency of the Knight motor is 23 per cent. and that in his judgment there was no reason why poppet valve types of motors should not deliver a near approach to this stated thermal efficiency. Mr. Chatain was of the opinion that if the shape of the cylinders, degrees of compression, and the other conditions are made to conform to the Knight practice in designing, the results obtained should be the same. In this discussion, however, the point was made that in the Knight type of motor the unjacketed and highly heated valve is done away with; the incoming mixture in the Knight type of motor is kept cool, due to the fact that the ports are water-jacketed, and the other advantage of the Knight type of motor lies in the fact that with two sleeves it is possible to time the motor in any desired way, duplicating the timing



Visiting the Chalmers plant

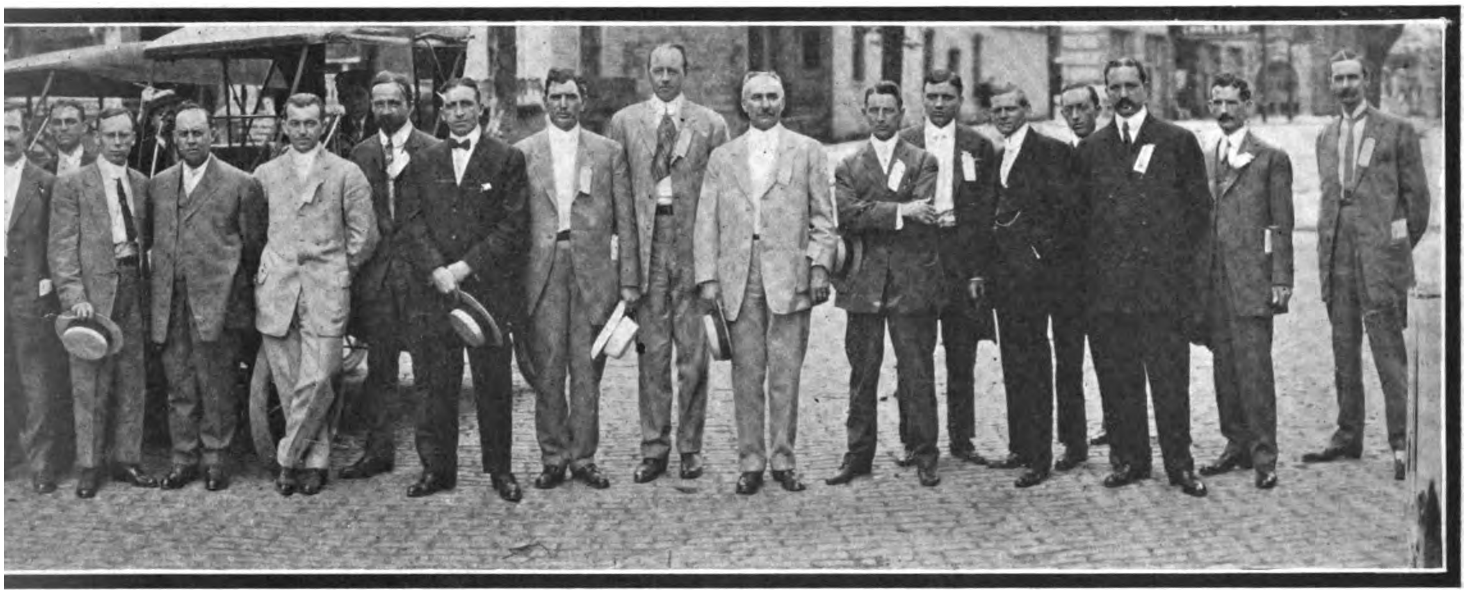


At the Aluminum Castings Co.



At the McCord Company's plant

of the poppet valve system if it is found to be the most advantageous. In discussing the merits of rotary valves, very little information of a positive character was extracted excepting that Mr. Ferguson said that a motor should be known by its performance. He went on to say that poppet types of motors are well known by their performance, which is decidedly good considering the mess of complication involved, and that the Knight type of motor was placed beyond the realm of speculation, due to its well-known good performance. According to this method of reasoning, the other types of motors may properly be judged after they generate a reputation of a substantial character. Mr. Brown, in pointing out that the struggle with other than poppet types of valves was for the purpose of eliminating noise, seemed to think that the undertaking might be carried beyond the necessities of the occasion; as he said, mudguards make noise, underpans rattle, transmission gears clatter, and the whole equipment is prone to become noisy as the road becomes rough, and the speed is increased sufficiently. It was Mr. Brown's contention, under the circumstances, that a little noise from the valve motion would scarcely prove discommoding. Other opinions on this point deprecated Mr. Brown's idea, culminating in an expression which, if re-written, might appear thus: Noise, due to the presence of ill-contrived members in an automobile, can scarcely be regarded as a license to put up with additional noise-producing tendencies. As one member stated, what customers want above everything else is silence of performance.



The paper entitled "Motor Trucks for Railroad Service," by T. V. Buckwalter, was interesting to the extent that it pointed out a new field of endeavor which has been worked up to a high state of efficiency, offering additional opportunity to automobile engineers to test their skill and widen the scope for investment.

It is rapidly being realized that the nomenclature of the automobile art is in a sad state of repair, and F. E. Watt at the request of President Coffin fired the first gun in what will probably prove to be a long and distressing task. Mr. Watt's paper, entitled "A Standard Automobile Nomenclature," was limited to a clever statement of the crimes that are being perpetrated daily, and he illustrated by means of a list of assembly groups some of the problems that must be solved in the long run, ending by recommending that a committee be appointed for the purpose of working upon this problem.

The patent situation, which is as acute as ever, was touched upon by E. J. Stoddard, in a paper entitled "The Establishment of a Court of Patent Appeals," which paper was sufficiently broad in scope to discuss the engineer's social relations. This paper adds substantially to the literature of the day, and it bears upon this important subject, bringing out pointedly the fix in which the average inventor finds himself and the fact that a patent is a mere license for a lawsuit. The most conspicuous point made was that a law-abiding citizen finds himself unable to determine whether or not he is infringing on a patent when he makes a machine, nor is he able, by any process of law, to put himself clear upon this point. The recommendation is for a Patent Court of Appeal, with power of last resort, as a proper substitute for 9 or 10 Courts of Appeal, which was said to be the foundation of the confusion that obtains in our present system.

Descriptive of the very latest methods of advance in the manufacture of gears, F. A. Ward presented a paper entitled "Making

Single-Cylinder Motor King at Boulogne

MOST distinctive in the mixed races at Boulogne-sur-Mer was the remarkable showing made by the single-cylinder, 3.9-inch bore, by 10-inch stroke Lion-Peugeot racers in competition against four-cylinder racing cars of very much larger bore. In the one-mile hill climb Boillot, driving one of the long-stroke machines, was clocked in 1 minute, 29 4-5 seconds, against 1 minute, 16 seconds for Camille Jenatzy's four-cylinder, 150-horsepower Mercedes of 6 4-5 by 6 1-5 inches bore and stroke. Although beaten by this leviathan, the Lion-Peugeot, while rated at only 6 horsepower, according to its bore, defeated the Benz, Prince Henry type, of 4 1-2 by 6 4-5 bore and stroke, driven by Heinz, a six-cylinder racing Rossel, a 4-inch bore Metallurgique, and was able to give 22 seconds to the Motobloc and Porthos, Grand Prix winners of 1908.

In the 300 metres hill climb, standing start, Camille Jenatzy made a record in 14 1-5 seconds, using the same Mercedes as for the mile climb. On the shorter distance the single-cylinders did not do so well, Giuppone, driving one of the Lion-Peugeots, making exactly the same time as the Grand Prix Motobloc racer, namely 19 4-5 seconds. This was better time than that of any of the big touring cars, with the exception of a Pipe of 6 1-5 bore by 7 inches stroke, driven by young Ferriol Jenatzy, who is the first example of a second generation of professional automobile racing men.

The event was a two-days' meet, opening with 7-kilometer straightaway tests over a switchback road with three sharp curves. The older Jenatzy's Mercedes was first in 2 minutes 55 1-5 seconds, equal to a speed of 89 1-2 miles an hour. Gaste on a six-cylinder Rossel, came second in 3 minutes 30 2-5 seconds, In the single-cylinder section Boillot came first in 4 minutes, 0 2-5 seconds, with his team-mates Giuppone and Goux, on similar cars, very close second and third. In the touring car section the fastest time was made by Joerns, on the Prince Henry type Opel, time 3 minutes, 29 1-5 seconds. Ferriol Jenatzy, in his Pipe, was second in 3 minutes, 34 1-5 seconds, with all the others in very poor position.

On the second day the road had become so sodden with heavy rain that Jenatzy did not dare start in his powerful Mercedes. Gaste on a six-cylinder Rossel, made the fastest time for the 1 4-5 miles straightaway, standing start. His time was 1 minute, 41 4-5 seconds. He was followed home by Heinz, on the Prince Henry Benz, in 1 minute, 42 3-5 seconds. All the others in this racing class were over two minutes covering the distance.

Boillot went over the course on his Lion-Peugeot in 1 minute, 53 1-5 seconds, followed by Giuppone on a sister car in 1 minute, 55 4-5 seconds. Among the touring cars best times were made by Ferriol Jenatzy's Pipe (6 1-5 by 7 inches), in 1 minute, 22 3-5 seconds, and Joerns' Opel (4 1-2 by 6 4-5 inches), in 1 minute, 43 1-5 seconds.

The mile hill climb placed Jenatzy's Mercedes first in 1 minute, 16 seconds; Heinz's Benz second in 1 minute, 31 seconds; Gaste's Rossel third in 1 minute, 38 4-5 seconds. In the one-cylinder class Boillot, on Lion-Peugeot, won in 1 minute, 29 4-5 seconds; Giuppone, on Lion-Peugeot, 1 minute, 37 3-5 seconds; Goux, Lion-Peugeot, 1 minute, 52 2-5 seconds. Ferriol Jenatzy's Pipe made the fastest time in the touring class, being clocked home in 1 minute, 22 3-5 seconds, with Joerns' Opel second in 1 minute, 30 1-5 seconds.

The 300 metres hill climb, standing start, placed Camille Jenatzy first with 14 1-5 seconds, beating the previous record held by Rigal on a Bayard-Clément. Best time for this hill climb in the single-cylinder class was 19 4-5 seconds. Ferriol Jenatzy's Pipe led in the touring class—time, 17 1-5 seconds.

Chicago Athletics Win Back Club Cup

CHICAGO, July 30—The third annual interclub reliability team-match between the Chicago Automobile Club and the Chicago Athletic Association, an amateur affair, was run July 28-29, going to St. Joe, Mich., and return, a distance of 132 miles each way. As a result, the Chicago Athletic Association regained the trophy which it won the first year and which was taken the second time by the Chicago Automobile Club. The C. A. A. team won because it had the fewest points against the thirteen cars which ran—55.3—while the C. A. C. had 77 points for eleven cars. Because of the uneven sides the former was penalized only 11-13 point per point.

The twenty-four cars got away promptly Thursday morning from the Chicago Automobile Club and the first day's itinerary included checking stations at Valparaiso, 60.4 miles; La Porte, 84.2; Buchanan, Mich., 110, and St. Joe, 131.8.

The second day's running brought penalizations only to six cars—two on the C. A. A. side and four on the C. C. C. Chamberlain and Thorne were the Cherry Circle unfortunates, while on the losing side N. H. Van Sicklen drew 5 points for work on the jackshaft; Charles Bosch had a motor stop; J. T. Brown an engine stop and L. E. Myers drew 20 points because of a clogged gasoline line. Chamberlain of the C. A. A. was the only one penalized the second day for being late—44 points.

Parade and Races at Opening of Beach Boulevard

JACKSONVILLE, FLA., July 30—The new Atlantic Boulevard, connecting Jacksonville with San Pablo Beach, was formally opened with an automobile pageant and parade on Friday. The road is 20 miles long and is considered one of the finest bits of road construction in the South. The surface is of cement, brick and gravel, and several concrete bridges have been installed. Work on this road commenced 20 years ago, but was abandoned and taken up several times before it was finally completed. Miss Marie Hyde christened the new road with a bottle of wine just before the start of the parade.

With an attendance between 7,000 and 10,000 the first racing of the season at the beach proved to be a success. The opening of the new road was the occasion of the meet. Before the races a parade was given around the city of Jacksonville and then the cars went out the new road, which had never been used before. More than 500 machines took part in the parade.

Three events were run off. The first, for cars in Class D, at two miles, was won easily by W. A. B. Worley in a Hupmobile in 2 minutes and 55 seconds.

The feature event of the afternoon was the second, in which there were five starters. Dr. Stinson's Oldsmobile won in 8

The third event, between an American, belonging to F. W. King, and the National of J. J. Logan, went to the latter, which covered the distance in 14 minutes and 27 3-5 seconds. Following are the summaries of the events:

Motor Trucks for Railroad Service

EXTRACTS FROM A PAPER READ AT THE S. A. E. CONVENTION BY T. V. BUCKWALTER, MEMBER SOCIETY OF AUTOMOBILE ENGINEERS.

The substitution of motor-propelled for horse- and hand-drawn trucks in railroad freight and baggage service is progressing rapidly, the Pennsylvania Railroad being especially interested along these lines. A field of usefulness for these trucks is also opening in railroad shop work.

THE development of the motor truck is the result of the demand for more rapid and cheaper transportation in industrial plants, in large terminal stations, and on our public thoroughfares. Manual labor and the horse have long been the sources of power for the operation of trucks, and the development of the steam locomotive in the last century has strengthened, rather than weakened their position, by greatly reducing the cost of transportation and increasing thereby the volume of freight. Steam, however, is performing the long end of the haul between distant points, leaving to the horse the shorter hauls of collecting and distributing goods at freight stations, and to manual labor the trucking between train and wagon platform. It is in these latter two fields that the motor truck is becoming, within certain limits, a successful competitor.

As applied to railroad service, motor trucks may be classified into three groups as follows:

First. Trucks utilized to replace box cars in the transfer of freight between different stations in the same city.

Second. Trucks to replace horse-drawn vehicles in the transportation of both passengers and merchandise on the public highways.

Third. Trucks to replace manual labor in the handling of baggage and mail in large stations, machinery and supplies in railroad shops, and in the transfer of freight in large freight and transfer stations.

The first group is limited to trucks of large capacity, and includes two general types, comprising, first, trucks propelled by either gasoline or electric motors and adapted to operate only on streets or other paved surfaces, and secondly, trucks driven by electric motors which normally obtain their power through a trolley in contact with an overhead street railway wire, but which on leaving the railway tracks obtain their current from a storage battery.

The second group, namely, trucks directly in competition with the horse, comprises taximeter cabs for the transportation of passengers at our large stations, as well as the general class of motor trucks used for freight delivery and for general service in our shops and offices.

The most important field for the operation of motor trucks is in the delivery and collection of freight, generally spoken of as "store door delivery." It includes the collection of freight from the sidewalk of the shipper and delivery at the door of the consignee, all handling being done by the transportation company or a subsidiary company acting as its agent.

Motor trucks in which power is brought into competition with man are represented by three general types, according to the service in which they are used. These are electrically operated baggage and mail trucks, shop trucks and warehouse trucks. All of these are for inside service, and therefore electricity is the only form of motive power available, on account of fire risks and odor.

The handling of mail and baggage in large terminal stations has increased to such an extent as to seriously hamper the expeditious movement of passengers and baggage, and requires the service of a large and constantly increasing force of men.

Recognizing the desirability of motor-propelled mail and baggage trucks that would decrease the time required to transfer baggage and mail from the receiving room to the train, and vice versa, the Pennsylvania Railroad Company about six years ago purchased two electric trucks and placed them in service at the Jersey City station. These trucks had a capacity of 4000 pounds, the weight of each truck being approximately 8000 pounds, but they proved too long and too heavy to operate to advantage.

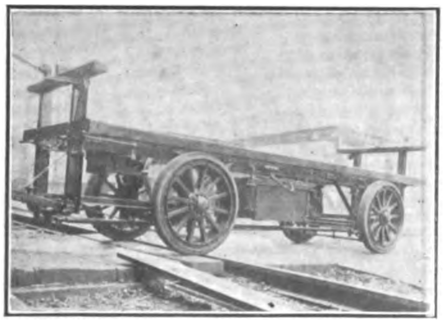
The next experiments were along the line of applying power to the standard hand trucks. About four years ago the company constructed two electrically operated mail trucks and one baggage truck and purchased a similar truck from another company.

The baggage truck consists of a standard baggage truck, with the exception that the front wheels are mounted on a knuckled axle, as used on automobiles, in place of the ordinary fifth wheel.

A twenty-volt motor is applied to each wheel, through double-reduction spur gearing; the motors are connected in parallel and act essentially as one motor; but the use of two motors obviates the necessity for a differential gear. Each motor is provided with an electric brake mounted on the armature shaft, consisting of a bronze disc, which rotates between a magnet and its housing, this disc being clamped between these surfaces by compression springs. In starting, the brake is released by passing current through the magnet.

The controlling apparatus consists of a master controller mounted in the steering handle of the truck. This master controller has three positions and is operated with one finger by being pulled forward against the action of a spring which tends to return it to the inoperative position. The first notch releases the brake; the second notch connects the battery with the motor through resistance; the third notch cuts out this resistance, allowing the truck to run at full speed. A reversing switch, mounted in the contactor box, is operated by a rod extending to the front of the truck. The speed of this truck is three miles per hour empty, and two and one-half miles loaded; its weight is approximately 2000 pounds.

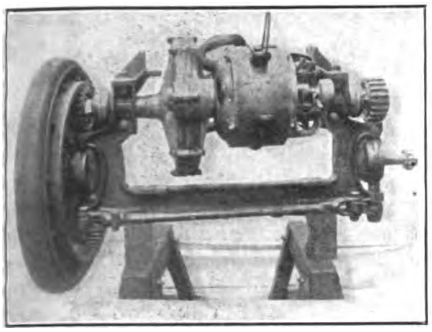
The mail truck consists of a standard mail truck with knuckled front axle. This truck, however, was provided with a single El-



Chassis of Buckwalter straight frame truck

Buckwalter straight-frame truck with load

Buckwalter drop-frame truck with load of baggage



Driving unit of Buckwalter truck showing "universal pinions," and steering-knuckle

well-Parker motor, driving through spur gear to the countershaft and by double side chains to the rear wheels. It is provided with a disc brake similar to that on the baggage truck. An indirect controller is used, consisting of three contactors operated by two drums in the master controller, one being used for forward movement and the other for reverse. The truck was also provided with a current-limit switch, to prevent the operator from starting the truck too quickly. The speed of this truck was about 4½ miles per hour empty, and about 3½ miles loaded, and its weight 2300 pounds. Neither the mail nor baggage trucks had provision for carrying the driver, it being necessary for him to walk in front as with the ordinary hand truck.

The principal characteristics of the new double-end electric mail trucks now in use at the Washington Terminal are as follows:

1. Arrangement of controlling apparatus to be operated with equal facility from either end, avoiding the necessity of turning on narrow platforms and runways.

2. Provision for driver to ride for the purpose of running at a higher speed; as a means of conserving his energy for transfer of baggage at his destination, and to give him more positive control of the truck.

3. Operation of brake with least effort and in a manner most natural to inexperienced men.

4. Reverse motion in natural manner.

5. Ease of steering, resulting in more positive control.

6. Flexible frame, on 4-point support to provide greatest stability, with each wheel carrying its quota of load.

7. Increase of tread so that wheels are just within protection of side sills and reduction of hub projection to rim of wheels, to reduce possibility of collision with railroad equipment, columns and other trucks.

8. Flexible suspension of batteries.

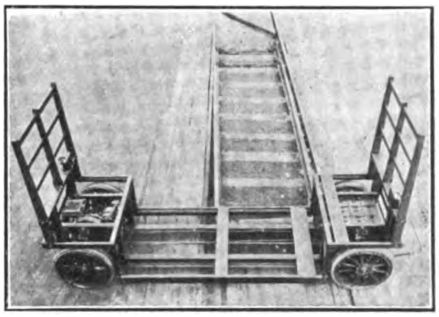
9. Direct operation of controller.

10. No projection of controlling apparatus beyond end sills of truck when not in use.

At the Jersey City Terminal there are now in use double-end electric baggage trucks with a length of twelve feet over the end standards. The height of the floor has been reduced to thirty inches, and the height over the end standards and the width were increased to seven feet and forty-four inches respectively. The carrying capacity has been approximately doubled, the trucks carrying eighteen to twenty-four trunks. The capacity expressed in pounds is 4000, while the weight of the truck is 2390.

On account of the limited space beneath the body it was found inconvenient to use the folding platform for the driver. A platform about eighteen inches square is provided at each end of the truck, and hinged to the end standards. These are connected by means of cable, so that when one platform is lowered to the operative position, the other platform is drawn up against a stop, thereby determining the position of the platform in use. The four-wheel steering arrangement is retained, the operating links, however, being considerably simplified. A single steering lever is provided which may be inserted in taper sockets mounted at each end of the truck.

Three speeds are provided in each direction, the second and third being made running speeds. The second speed is from four to five miles per hour, and the third from five to seven miles per hour, depending upon the load and grade.



Plan view of Buckwalter drop-frame truck

Practically no change has been made in the method of driving the new trucks, with the exception that the countershaft and motor gearing are enclosed within an aluminum housing and run in oil; furthermore, on account of the limited space available, the universal pinions engage with internal gears which are an integral part of the rim of the driving wheels. The strength of the gear teeth is greatly increased by utilizing the twenty-degree stub tooth.

The brakes are of the internal-expanding type, but are mounted on the trailing wheels instead of the driving wheels as on the Washington trucks. The introduction of a divided expanding pin in alignment with the steering knuckle has resulted in a uniform application of the brake regardless of the direction the truck is running or the end from which the brake is applied. The same size motor is used, but the capacity of the battery has been increased to 196 ampere-hours. The battery is composed of twelve cells, mounted in one tray, which is spring-supported and readily removed. A battery transfer system is in use at Jersey City, by means of which it is possible to change batteries and keep the trucks in operation twenty-four hours a day.

The wheels are twenty-seven inches in diameter, of the artillery type, with malleable hubs, wood spokes and steel rims, fitted with three and one-half-inch solid rubber tires. The rim is made in two sections and clamps the spoke in such a manner as to avoid reducing the size of the spoke, where it is ordinarily tenoned in a wood felloe. This arrangement permits of using any of the standard methods of tire fastening and is a stronger and lighter construction than the standard artillery wheel.

The steering-knuckle is of a special form which reduces the projection of the hub beyond the side sills of the truck to only three-fourths of an inch. The side sills are also of a special section of pressed steel that provides a round metal roll on the top of the floor line, to take the wear of loading and unloading baggage. This construction also permits the removal of one floor board without disturbing the others. The end construction is also of pressed steel.

The trailing axle is interchangeable with the axle on the driving unit, but brake-hangers are provided in the bearings, which on the driving axle carry the countershaft housing. A wheel with the brake is shown in position, while on the other end of the axle the wheel is omitted to show more clearly the relative position of the brake band and steering-knuckle.

The use of motor trucks in railroad shops may be considered as a logical development from electrically-operated baggage trucks. Manufactured articles and supplies must be hauled from storehouses to engine houses; rough castings are carried from casting-yards and forgings from smith-shops to various machine shops, where, in the case of complicated pieces, they may be still further transferred from machine to machine, and finally be hauled either to the erecting shop or a storehouse. In addition to this, there is a considerable transfer of supplies and manufactured articles between the various storehouses. It is the practice to do most of this hauling with four-wheeled hand-operated trucks, but with the development of the electric baggage truck an extensive field for motor trucks to handle this industrial service is opened. Instead of four men to a truck with a load of possibly one ton, one man can easily operate an electric truck with a load up to 4000 or 5000 pounds, at about double the average speed of the hand truck. Space, however, is more restricted in shops than on baggage platforms, passageways more narrow, which renders a somewhat smaller truck desirable.

Establishment of a Court of Patent Appeals

Extracts from a Paper Read at the S. A. E. Convention by E. J. STODDARD.

THE engineer and scientist is being summoned, with the inevitable and irresistible force of the "mill that grinds so fine," to bear an important part in regulating social relations. Fully half of our educated men are educated scientifically. A quality of masculine strength and steadiness is recognized in them that promises a building up with adequate and substantial foundation that shall secure efficiency and permanence.

The organized bodies of engineers are recognizing the call to public duties. The American Society of Mechanical Engineers, for instance, has a number of committees on public relations.

The applied sciences are fairly well intrenched as to their general rights, but the "remedies" are lacking, imperfect, inapt, or inefficient in their application. Attention should be especially given to a limited field capable of fairly definite formulation, where some sort of a legal remedy is provided by statutory law to perfect a long recognized "general right" of the engineer.

Intellectually, the engineer may be of service in two ways: by bringing into use existing knowledge, or by bringing into existence a new idea. The last is called invention, to which all good acquired by the effort of man is to be ascribed; its accomplishments are the just measure of civilization.

Public sentiment has forced legislation, but its expression in legislation and by the courts has been somewhat imperfect, as far at least as the engineer is concerned. The formulators of the laws have not been effectively advised by those who are most concerned.

In the *North American Review* for January, 1905, Mark Twain, writing upon the "Copyright Laws," touches also upon the patent laws, and brings out distinctly the contrast between the intention of the laws and their results. His article is in the form of questions and answers. He says:

"Q. Certainly there is something most grotesque about this. Is this principle followed elsewhere in our laws?

"A. Yes, in the case of inventors. But in that case it is worth the Government's while. There are a hundred thousand new inventions a year, and a thousand of them are worth seizing at the end of the seventeen-year limit. But the Government can't seize the real and great immensely valuable ones—like the telegraph, the telephone, the air-brake, the Pullman car and some others—the Shakespeares of the inventor-tribe, so to speak; for the prodigious capital required to carry them on is their protection from competition; their proprietors are not disturbed when the patents perish. Tell me who are of the first importance in the modern nation.

"Q. Shall we say the builders of its civilization and promoters of its glory?

"A. Yes, who are they?

"Q. Its inventors; the creators of its literature; and the country's defenders on land and sea.

"A. I think so. Well, when a soldier retires from the wars the Government spends $150,000,000 a year upon him and his, and the pension is continued to his widow and orphans. But when it retires a distinguished author's book, at the end of forty-two years, it takes the book's subsequent profits away from the widow and orphans and gives them—to whom—"

He concludes that these subsequent profits go, not to the public for whom they were intended, but to the publishers who give no adequate return.

It is the will of a generous people that the road to honor and wealth should be free and open to the intellectual creator. The expression of this will is confused and indistinct. What can be done about it?

A distinct step in that direction, which specially concerns the engineer, may be taken in the immediate future, and bids fair to be embodied in a law even by the present Congress.

It is proposed to create a court of practically final resort to hear appeals in patent cases, to take the place of the nine or ten Courts of Appeals now existing, with their conflicting decisions and numerous disadvantages.

The necessity of such a court is obvious and pressing. The bill creating it has been favorably reported on by the House Committee on Patents and by the Senate Committee on Patents. It has been referred to the Judiciary Committee of the House, and is now before that committee.

The bill provides for the appointment of a Chief Justice by the President of the United States, in the usual way, and that the Chief Justice of the Supreme Court of the United States shall designate four Federal Judges to sit as Associate Justices, for a term of six years.

There are certain technical difficulties that the establishment of this court will surely cure. These are ably set forth in a printed argument prepared by the Committee of the Patent Branch of the American Bar Association. This argument is plain, unanswerable, and it will be sufficient to carry the bill through. But no effort ought to be omitted.

There are, however, outside of strictly legal matters, a number of considerations that should appeal to a society of engineers.

There are many complaints of the present administration of our patent laws. Such complaints are in a large measure just, and the faults remediable. But in remedying existing faults we do not want to introduce greater faults or destroy a right that should be the most sacred and firmly based of all rights to property.

In establishing this court the service of the whole people must be kept in view, not that of any class or profession. It should not be a court in the interest of manufacturers, of engineers, or of lawyers, but a court that shall administer justice intelligently and carry out the will of the people as a whole.

In patent cases the questions of fact are questions of mechanics, engineering and science, and they are so interwoven with questions of law that the dividing line vanishes. The value and meaning of a decision as a precedent depends, often, upon the facts.

The American Bar Association Committee on the Court of Patent Appeals says in part in its argument, referring to the confusion due to the conflicting decisions of our nine or ten Courts of Appeal:

"The truth is that the worst effect of the existing situation is that it undermines confidence. It demoralizes the bar. A lawyer does not know how to advise his clients. It tempts both attorney and client to take chances. The law-abiding citizens who want to obey the law, who want to respect valid patents, but do not want to be terrorized into acquiescence in invalid patents, do not know what to do and cannot find out. There is but one remedy, and it is in a single court of last resort in patent causes."

Professor John Perry says that in England the inaptness of their judges in scientific matters is threatening confusion and disaster in this line. If this court is established, America will be taking the lead in providing for the creation of a just and rational system of jurisprudence relating to intellectual property. We believe this is as it should be and in the line of precedents.

Engineers generally should use their best efforts to have the bill in its present form enacted into a law, and watch with friendly interest its working when established, recognizing special ability in any of its judges, when it shall be shown, and being ready to advise if it shall be necessary to take any measure to increase its efficiency.

They say to properly state a problem is to half solve it. When we shall have established this court we will have something definite upon which to concentrate our influence, and to hold responsible. The problem will at least have been stated.

Rejuvenating the Old Automobile

By G. J. Mercer

This effort, following along lines involving the rejuvenation of other makes of cars, has for its subject the Haynes "Thirty" model, with a view to changing it over to a Cruiser type, utilizing the old body to the extent of its adaptability.

As in previous undertakings of this character, the new body is shown in Fig. 21, and the details for the guidance of the repairman are given in Figs. 22, 23 and 24. Glancing at Fig. 23, it will be observed that the speed-changing lever falls to the inside of the body, and the emergency brake lever is given a kink at a point just above the quadrant to bring it outside of the body line. The relations of the levers are also indicated by dotted lines in Fig. 22, which figure has the further facility of indicating the dimensions and scheme of framing for the new front door, while the plan, Fig. 24, helps in the proper understanding of the case. The pillar A, Fig. 22, is bent to form the outline of the door, the moulding around the door covers the screws that are used for fastening, and No. 16-gauge aluminum is specified for the panel. The hooded dash is flared from the contour of the hood and brought out sufficiently to accommodate the door which swings to the front and should be fitted with hinges and a handle of the same style as used on the tonneau doors. The right side of the frame is similar to the left, minus the cut for the door, remembering, however, that there is an opening to be provided for the change lever. It is fortunate that the change lever does not have to be altered in any way to bring it within the body in the manner as shown. The quadrant, however, comes rather high above the chassis, and the body must be cut away to accommodate the same. In the framing process, the workman will understand that the offset of the pillar A, Fig. 22, is only 1 1-2 inches out from the underbody at the bottom, and the finish corresponds to that of the rear doors. The amount of work involved in the conversion of the old body to conform to the new requirement is relatively slight, and in the hands of a capable workman the cost should not be high. It will of course be necessary to refinish the whole body, and in this undertaking it will be worth while to do the work so well that it will not be possible for an observer to pick out the new from the old work. The best way, perhaps, is to start from the ground and work up, making the finish uniform over all of the surfaces, and the slight extra cost involved in the more pretentious process will be compensated for by the extra time of service under conditions of a satisfactory appearance of the body.

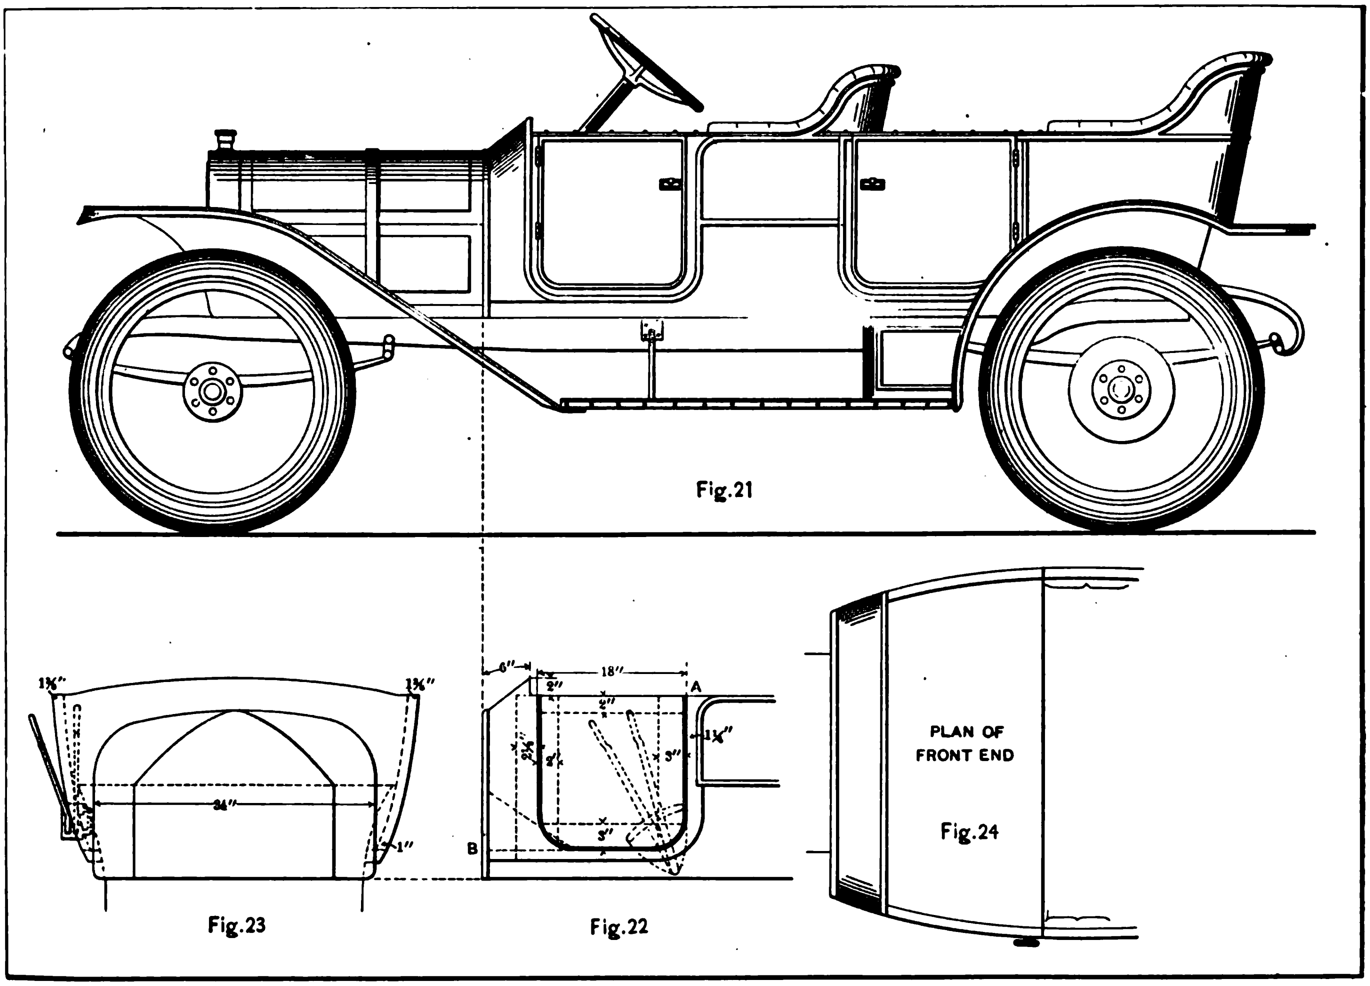


Fig. 21—Haynes "Thirty" model, with new fore-door type body replacing old touring style. Fig. 22—Detail of new fore-door. Fig. 23—Front elevation. Fig. 24—Plan of front end

A Good Finish for Refurbishing the Old Car

After selecting the desired color mix it with raw linseed oil and turpentine in the proportion of one part oil to eight parts turpentine, using a good camel's hair brush to apply it to the surface. After thoroughly dry, lay on a generous coat of heavy body-finishing varnish.

Letters Interesting, Answered and Discussed

Effect of Time and Temperature on Hardening

Editor **The Automobile**:

[2,337]—I run a small garage in a country town and have to make repair parts frequently requiring hardening, and desiring to deliver better satisfaction than that which can be afforded under ordinary conditions, I have installed a small gas furnace for hardening purposes, but find myself in a quandary in relation to the time I should take in the hardening process and to the temperature required for the best results. There probably are other small garages with similar problems to cope with and a little information on this subject should be timely. A. C. S.

With the advantages offered by a small gas furnace, it remains to either employ a pyrometer in the determination of temperature or become familiar with the color which corresponds to a given temperature, judging by the eye. The effect of time, considering temperature, as it relates to penetration, is shown in Fig. 1. The curve marked 850 degrees centigrade represents the results obtainable with the lowest temperature of cementation, and the curve marked 1000 degrees centigrade gives the penetration, also the highest temperature which should obtain. It will be understood, however, that some one temperature should be held to throughout the carbonizing operation. Just what temperature to adopt depends upon the composition of the steel. If it is very low in carbon the temperature may be relatively high, but if the carbon content is relatively high, the temperature during carbonization should be more carefully regulated. As the curve shows, a penetration of 0.030 of an inch will be had inside of about 1 hour and 50 minutes, if the temperature is maintained at 1000 degrees centigrade, whereas at 850 degrees centigrade the same penetration would require about 3 hours and 55 minutes. These values are relative. If the steel is the usual low carbon product of the market with a carbon content of about 10 points, the temperature should not exceed 1,000 degrees centigrade and good result will come if the same is limited to 900 degrees centigrade. In no case should the steel have more than 20 points of carbon if it is to be subjected to the casehardening process. This process is described in various ways as "casehardening," "cementing" and "Harveyizing"; it is sometimes described as "carbonizing." By penetration is meant the depth to which the carbonizing process is carried in the steel. If the steel is high in carbon the core will not remain soft, nor will the case be dynamic. The way to obtain a soft core and a dynamic case is to start out with mild steel, limiting the carbon content below 16 points in any event (20 points as an absolute limit) and holding to approximately 10 points if possible. The core of the cemented steel will then have the softness and dynamic ability of 10-point carbon steel, whereas the shell or case will have the hardness due to 100 points of carbon, it being true that in the carbonizing process, while a point of saturation is never reached, the carbon content does increase to even a higher level than 100 points of carbon.

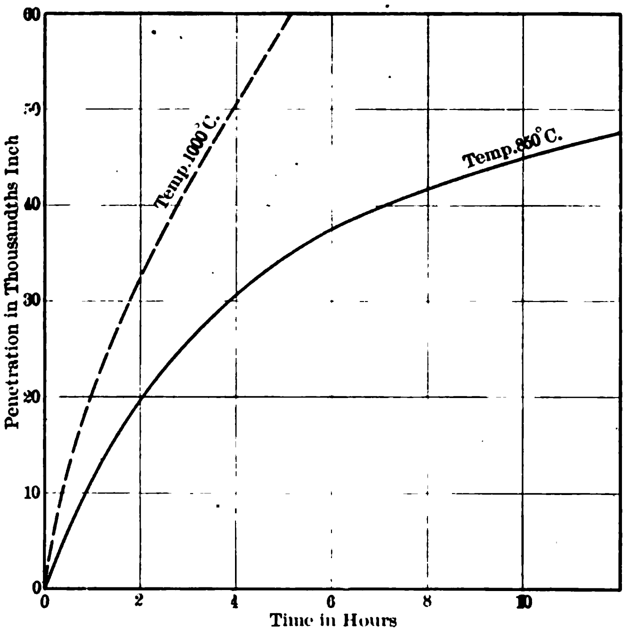

Fig. 1—Diagram showing effect of time, considering temperature, as it relates to penetration, in hardening metal in a gas furnace

Judging temperature by color is not an exact science, especially when the room is more or less flooded with light; if comparison is made in a dark room the results will be more satisfactory. The following tabulation is generally accepted as satisfactory in work of this character:

TEMPERATURE CORRESPONDING TO COLOR DUE TO HEAT

Temperature Deg. F.	Color
977	Incipient red heat
1,292	Dull red heat
1,472	Incipient cherry red
1,650	Cherry red
1,832	Clear cherry red
2,021	Deep orange
2,192	Clear orange
2,372	White heat
2,552	Bright white heat
2,732	Dazzling white heat
2,912	Sweating white heat

To find the equivalent temperature in degrees centigrade for the temperature as measured in degrees Fahrenheit proceed as follows:

$$\text{Degrees centigrade} = \frac{(\text{Degrees Fahrenheit} - 32) \times 5}{9}$$

To find the equivalent temperature in degrees centigrade for the temperature as measured in degrees Fahrenheit—

$$\text{Degrees centigrade} = \frac{(1{,}832 - 32) \times 5}{9} = 1{,}000$$

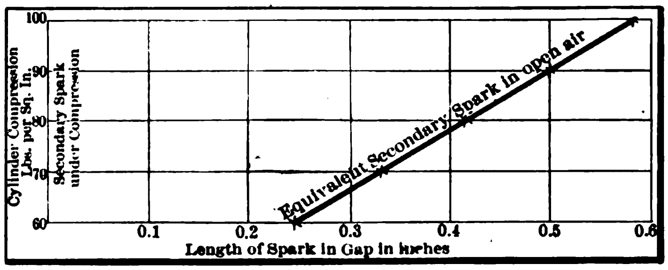

Fig. 2—Diagram showing increase in resistance of spark gap under gas compression in cylinder as compared with same in open air

Thus it will be seen that the highest temperature desirable for cementation is that which corresponds to the clear cherry red, i. e., 1,000 degrees centigrade, the equivalent of which is 1,832 degrees Fahrenheit.

It is believed that the depth of the carbonized shell should be at least 1-32 of an inch, and if the operator does not know the composition of the steel he may find out whether or not it is suitable for this work by proceeding as follows: Heat the steel to a clear cherry red temperature, at which temperature quench it in a bath of salt water, after which if it shows no perceptible increase in hardness as tested by a file it will be suitable for casehardening work.

Resistance of Spark Gap Rises With Compression

Editor **The Automobile**:

[2,338]—In struggling with ignition trouble on my motor I was much puzzled, due to the fact that when I took the spark plugs out of the cylinders and tried them, I noticed distinctly that there was a spark, but when I put them back in place there

seemed to be no result. After trying everything else I finally substituted a new set of dry cells, when, to my astonishment, the motor worked beautifully. It strikes me that I am confronted by a condition that I do not understand, and I refer it to you with the full assurance to myself that an explanation will be forthcoming.

Red Wing, Minn. SUBSCRIBER.

The amount of information afforded with which to arrive at an accurate conclusion is rather meagre, but the probabilities are that what you needed was a new battery, and the reason you obtained the spark in the open air, but not after the spark plugs were put back into the cylinders, is due to the considerable increase in resistance of the spark gap under gas compression in the cylinder as compared with the resistance of the same in the open air. Fig. 2 as here given shows the relation, in which it will be observed that for a compression of 60 pounds per square inch the equivalent secondary spark in the open air must be about 25-100 of an inch long. This equivalent secondary spark in the open air must be increased in length as the compression increases in the cylinder in order to be sure that there will be a spark in the cylinder under compression; for instance, a spark in the open air 1-2 inch long will barely assure that there will be a spark in the cylinder sufficient for the need under a compression of 90 pounds per square inch.

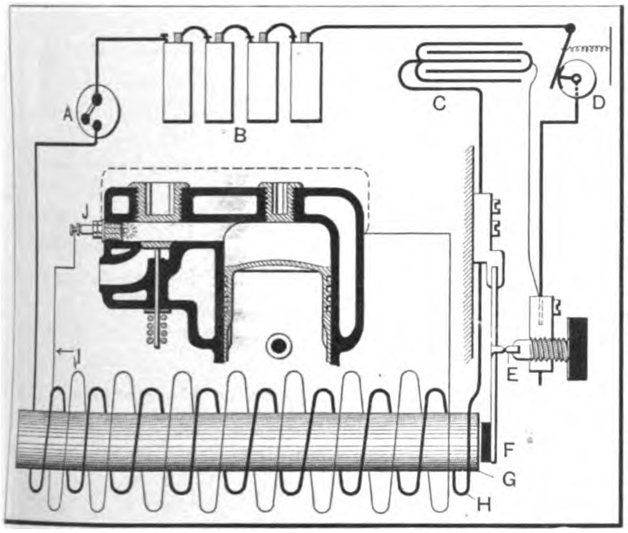

Fig. 3—Diagram of the connections in an ignition system

Cylinder in Question Holds 40 Gallons of Gas

Editor THE AUTOMOBILE:

[2,339]—You stated on page 114 of THE AUTOMOBILE of July 21 that a cylinder measuring 3 1-2 x 13 inches contains about 14 gallons of gas. This looks to me too low a figure.

Hartford, Conn. OXYGEN.

According to James S. Madison, the author of this article, the right figure for the capacity of the tank in question is 40 gallons.

Wants Push Button on the Steering Wheel

Editor THE AUTOMOBILE:

[2,340]—I have a four-cylinder, air-cooled motor to which I wish to add a push button to make the engine start on the spark. I would thank you to tell me how to go about wiring same in the simplest way, so that by pushing a button (separate from the coil) a spark will be obtained at all the plugs at one and the same time.

Jeanerette, La. C. R. P.

Automobile supply dealers are in a position to furnish well-contrived forms of push buttons which may be placed on the steering wheel, and a very good way to make the wiring connections is to take the ground wire from the battery, lead it to the push button on one side and ground the push button on the other side on the steering wheel. It will be understood that what is technically designated as a "ground," is accomplished when the ground wire is led to any part of the metal framing of the chassis or motor, so that the framing itself, being a conductor, becomes a substitute for one of the electrical connections. The battery being grounded on one side will be grounded in just the same way if one of the leads from the push button is connected to the metal steering wheel.

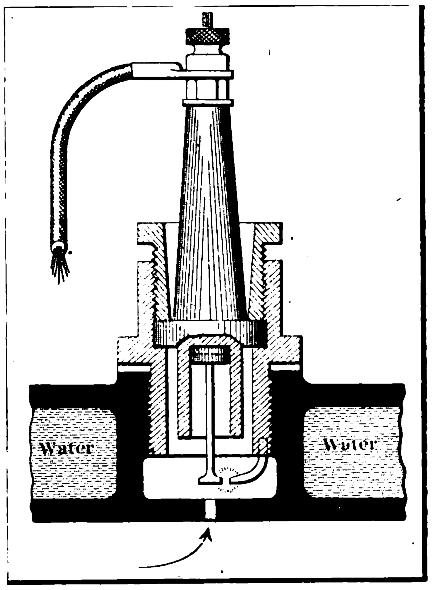

Fig. 4—Spark plug in cylinder head cast with perforated wall at bottom of plug well to protect spark points against fouling.

Connections for Condenser in Ignition System

Editor THE AUTOMOBILE:

[2,342]—I understand in a general way the necessity of employing a condenser as a part of the equipment in an ignition system, but it looks to me as if the condenser as connected up in my car acts to short-circuit the system. One lead from the condenser traces to one pole of the spark gap, and the other lead seems to me to go directly to the other pole. Does this not short-circuit the spark gap of the trembler?

White Plains, N. Y. R. C. N.

According to Fig. 3, a diagram that fits your case, the condenser C is in parallel with the contents E of the trembler. When the switch A is closed, current is supplied by the battery B when the circuit is closed by the timer D, and with the first rush of current across the contact E the core G is magnetized, and due to the change in magnetic flux an electromotive force is set up in the primary wire H, and by induction an electromotive force is impressed on the secondary wire I, thus causing a spark at the spark plug J. When the magnetic flux in the core G is strong enough, it draws the hammer F on the end of the tongue at the trembler, thus opening the circuit at the contacts E, and the condenser C, being in parallel, absorb energy at one point in the wave, delivering it back again to the circuit at another point.

Protection of Spark Plugs the Idea

Editor THE AUTOMOBILE:

[2,341]—I have an air-cooled motor with the spark plugs placed in direct contact with the flame in the combustion chamber, and I use either poor lubricating oil, or the spark plug is in the wrong place. It occurs to me that I might protect the spark plugs to good advantage by not permitting direct flame contact.

Kansas City, Mo. IGNITION.

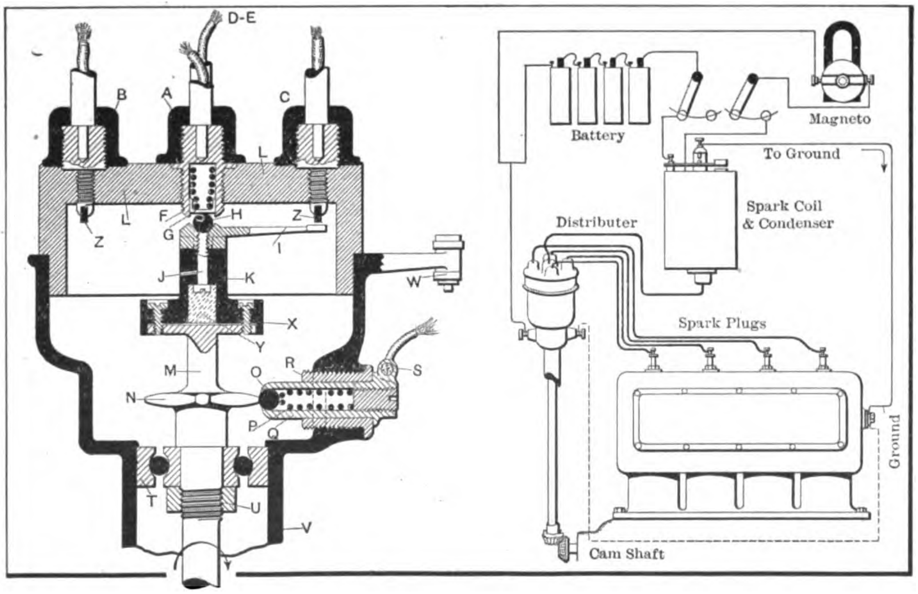
The first thing to do is to acquire the habit of using good lubricating oil. A poor grade of lubricant is likely to "crack" under conditions of high temperature. Fig. 4 shows a plan that seems to work very well indeed, but it may not be possible for you to rearrange your cylinders in order to enable you to take advantage of the ignition chamber as shown. The diameter of the hole leading from the ignition chamber is about 1-8 inch.

Questions That Arise—General In Scope

Discussing single coil for sparking systems; fuel value of gasoline in B.t.u.; relations between air and metal in cooling systems; relation between diametral and circular pitch of gears; gasoline combustion products.

[187]—In some sparking systems for automobile motors a coil is used for each cylinder, but in a few examples one coil is made to serve for four cylinders. How is the single coil connected up to do the work ordinarily requiring four coils?

When one coil is employed for four cylinders instead of one coil for each cylinder, the high-tension distributor must be employed and the connections are as here shown. The current passes from the battery through a switch to the coil through the trembler with the condenser in parallel across the contacts of the trembler. From the coil a single high-tension lead passes out of the bottom and to the central terminal at the top of the high-tension distributor. The high-tension current is distributed to the four spark plugs on the motor, and connections are completed through ground returns as indicated by dotted lines on the diagram. A better understanding of the functions of the high-tension distributor will be realized by examining the section to the left in the illustration which is of the same. This distributor performs two independent functions, one of which is that of a timer which closes the primary circuit in accordance with the relations fixed in timing the motor, S being the terminal of the primary circuit, R is the insulating bushing, and O is the contact which is held into relation by means of a spring so that when the four high spots N on the enlargement of the shaft rotate with the shaft, they make contact 90 degrees from each other. The shaft is vertical and the bearing T in the housing V centers the same, it being held on the shaft by the locking ring U. The upper end of the shaft M has a flange Y at an insulating piece X fit thereto. Screws K hold the insulating piece to the flange, and the finger I is fastened to the upper end of the insulating piece, being held in place by the screw J. Contact is made between the finger I and the central lead E through the ball H and the terminal piece F into which the terminal of the lead E is soldered. A spring presses the ball H into the socket formed in the finger I. The cap of the timer L is of insulating material, and the terminals A, B, C and D are spaced equidistant around the same, with the central terminal E in proper relation. When it is desired to advance or retard, the spark motion is imparted to the distributor by the lever W, which, by suitable links and motions, connects with a lever on the steering post. The finger I makes the connection from the central electrode E to the electrodes A, B, C and D respectively, which in turn are connected to the respective cylinders of the motor, so that a high-tension current is delivered to the respective cylinders with an equal measure of time between sparks, but since only one coil is employed it must serve as a transformer of the step-up character for four cylinders, whereas in the unit coil work there is a step-up transformer for each cylinder, thus eliminating the necessity of using a high-tension distributor. It will be understood, of course, that the high-tension distributor eliminates the need of three of the four coils.



Cross-section of high-tension distributor and plan of wiring for a four-cylinder motor

[188]—What is the fuel value in British thermal units per pound of the contents of gasoline?

According to accepted authority, these values are as follows:

Carbon burned to carbon monoxide....................	4,100 B.t.u.
Carbon burned to carbon dioxide.......................	14,500 B.t.u.
Hydrogen burned to water............................	62,032 B.t.u.
Hydro-carbons burned to carbon dioxide..............	20,000 B.t.u.

From the above it will be seen that a small proportion of hydrogen in the exhaust products of combustion of a motor represents an enormous weight. It will also be noted that unburned gasoline in the exhaust represents a very considerable waste, and that carbon monoxide, if it exists instead of carbon dioxide, lowers the thermal value of the fuel as used from 14,500 to 4,100 British thermal units.

[189]—To what extent is incomplete fuel combustion present due to load changes in a motor?

One test as reported shows changes in a thermal efficiency due to different loading as follows:

EFFECT ON THERMAL EFFICIENCY OF CHANGES IN LOAD

Products	Full Load	Part Load
Carbon monoxide....................	3.31	6.9
Hydrogen	1.19	2.4
Hydro-carbons	0.30	0.9
Carbon-dioxide	11.90	9.9
Oxygen	0.23	0.3
Nitrogen	83.07	79.6
Total	100	100

It will be seen that the carbon monoxide content is nearly doubled with the part load as compared with the full load. Hydrogen is also nearly doubled, under the same conditions, likewise the hydro-carbon is wasted on a considerably increased basis. The carbon dioxide content is maximum under full load, as it should be, and is reduced considerably with part load, which is a misfortune. The amount of oxygen present is maximum under part load, but in excess under both conditions; this, under the circumstances, is probably a necessity since it seems to be impossible to burn automobile gasoline excepting with an excess of oxygen present. The excess of oxygen was apparently greater under full load conditions than it was with the part load because the nitrogen content is greater with the full load. The ratio of oxygen to nitrogen being constant, it is a fair inference that the amount of air used under the part load conditions was less in proportion than under the full load conditions. From the information thus afforded it is reasonable to expect that the thermal efficiency of a motor will be difficult to maintain when the load is reduced, and that there is some one point in the range of speed and load of a motor at which the thermal efficiency will be maximum.

In other words, the thermal efficiency is not constant under conditions of changing speed and load.

[190]—What are the relations between the air as it is propelled by a fan by the radiating surfaces of a cooler, and the conducting ability of the metal used in making the cooler?

As compared with any metal, air is a poor conductor of heat; it follows therefore that any metal as used in radiator construction is capable of delivering more heat to the radiating surface than the air can take away unless the difference in temperature between the cooling air and the metallic surface is relatively great. The ability of air to absorb heat is of course limited to its specific heat, and to the difference in temperature between the entering and leaving air. The specific heat of air is very low, and the real problem is to have a very thin sheet of same spread out over the cooling surface. In order to increase the efficiency of the air current as it involves the cooling surface, circulation is set up; this is but another way of disregarding the poor conductivity of air for heat. Instead of the heat having to traverse the air body, the molecules of air are brought successively into contact with the heated surface of the radiator, and as each molecule of air absorbs its quota of heat, it is borne away in the stream. The efficiency of the process depends upon the number of molecules of air that are successively brought into contact with the heating surface.

[191]—What is the relation between diametral and circular pitch of gears?

The circular pitch may be ascertained as follows:

$$\text{Circular Pitch} = \frac{\pi \times \text{Pitch Diameter}}{\text{A number of teeth}}$$

Conversely,

$$\text{Diametral Pitch} = \frac{\text{Number of teeth}}{\text{Pitch diameter}}$$

Numerically,

RELATION OF DIAMETRAL TO CIRCULAR PITCH

Diametral Pitch	Circular Pitch
4	0.785
6	0.524
8	0.393
10	0.314

[192]—What are the products of combustion of automobile gasoline, and in what proportions?

When the gasoline is burned completely, the products of combustion are carbonic acid and water with a small percentage of ash. As a general rule combustion is not complete and carbon monoxide, hydrogen, carbon and hydro-carbon compounds are found in the exhaust. The percentages of the contents of the exhaust vary over wide ranges depending upon the conditions, but according to Bertram Hopkins (paper read before the Institute of Mechanical Engineers at London, England, February 10, 1909) the following exhaust analyses were made, and they should afford an insight into the subject sufficiently for the purpose here. The engine used was a Siddeley.

REPORT OF TEST KNOWN AS TABLE VI

	A1	A2	B
Speed	530	535	930
Gasoline per thousand revolutions (lbs)	0.42	0.375	0.333
Reported Exhaust Analysis:—			
Carbonic acid (CO_2)	13.55	13.4	13.1
Oxygen (O_2)	0.55	1.8	1.3
Carbon monoxide (CO)	0.8	0.0	0.3
Residuum	0.5	0.35	0.7
Air per suction per cylinder	0.041	0.0395	0.0335

It is claimed that under the above conditions the air per suction stroke is about 20 per cent. greater at 530 revolutions than at 930 revolutions per minute. The ratio of air and gasoline vapor to stroke volume is 83 per cent. at the former against 69 per cent. at the latter speed. This condition is due to the better "filling" of the cylinder at the lower speed.

Making Gears Quiet by Grinding

By F. A. WARD

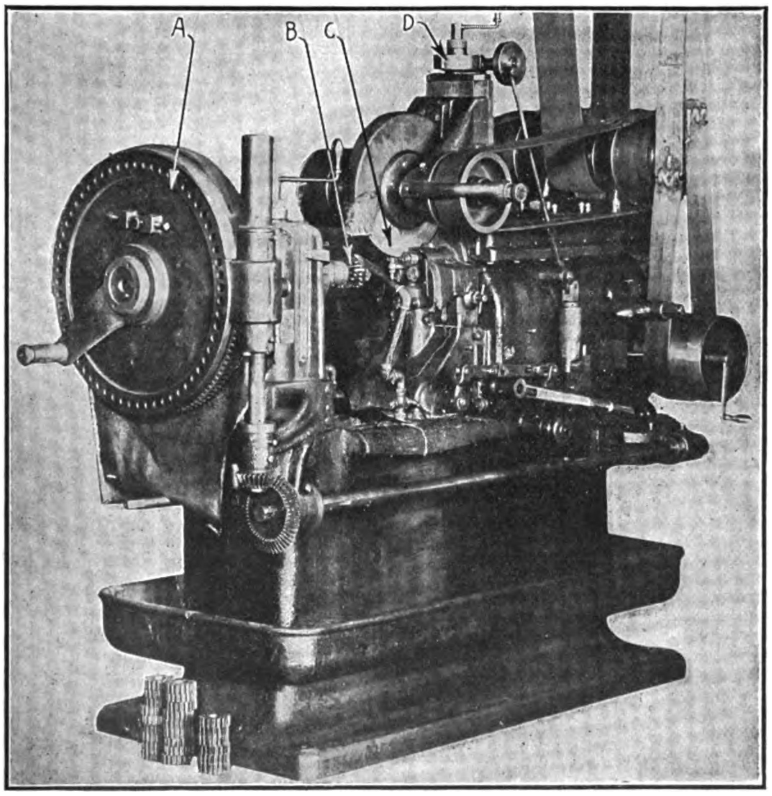


Fig. 1—A, indexing wheel; B, gear to be ground; C, grinding wheel being trimmed; D, automatic device for feeding wheel down as it wears away

THE automobile engineer in considering the gear problem faces several conditions. The gears used must be sufficiently strong and so designed as to withstand not only a constant operating load, but also sudden shocks that may arise from inexperience or other causes. Also, the public demand a quiet-running gear. There must be skin-hardening of the surface of the gear to give commercial life. After determining the load factor some suitable pitch is chosen, and the form of tooth and the pressure angle are decided upon. The material to be used is also determined. With the above data perfect gears could be secured to meet all conditions except as to wearing life. The hardening of gears sets up inaccuracies which it has been impossible for the engineer to overcome.

Gears may be heat-treated and casehardened and allowed to change in physical form to the fullest extent, but a machine must be devised to restore them to perfect form at a commercial cost. Prior experimenters have generally tried to use a thin abrasive wheel, whose revolving perimeter would trace up and down the curve of the gear tooth. But the wear on such a wheel was marked, and it was found impossible to maintain it continuously to form. The basic idea was to use a unit area of grinding wheel to the unit area of surface to be ground and to maintain this unit area of grinding wheel to the constant form desired by means of some trimming device. A first experimental machine was completed in 1907. From then until the latter part of 1909 the

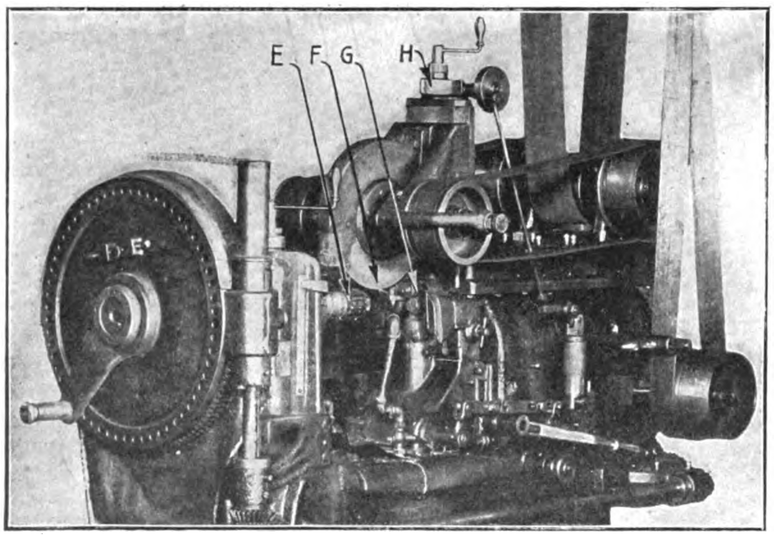

Fig. 2—E, gear to be ground; F, grinding wheel just before entering gear; G, grinding wheel automatic trimming device; H, automatic device for feeding wheel down as it wears away

machine was in process of development. During the early part of this year it was the practice to grind rough-cut hardened gears with such a degree of accuracy that in measuring a group of teeth the variation from theoretically absolute accuracy has been less than .001 inch or less than .0002 inch per tooth. The machine has also obtained such speed as to make it a success.

There are here illustrated the present Type A grinders, which are designed to handle a line of gear work from the smallest up to and including 12 pitch diameter, as heavy as 4 pitch and with a face dimension up to 4 inches. The gear, rough-cut or as the case may be, with stock allowed for finishing in the grinder, is mounted upon an arbor in a manner similar to that employed in gear-cutting. By means of a number of well-known mechanical movements the grinding wheel, revolving at a proper rate of speed, is brought forward and passes with a shaperlike movement between the gear teeth. This grinding wheel is of a grade suitable for grinding the material of which the gear is made, and is kept continuously to the required form by means of an automatic forming device.

In order to grind gears successfully the indexing device is of the utmost importance, as the extreme of accuracy is required. A newly developed indexing device has eliminated the common trouble arising from friction driven indexing devices and is now used upon the machines.

For obtaining the required number of divisions the common method of change-gears is employed.

The forming device is a simple combination of mechanical movements. Any standard form of spur gear teeth and many so-called freak forms are easily developed upon the sides of the grinding wheel and rapidly reproduced upon the gear.

Within this device, not visible in the illustrations, is a master form, which is mathematically calculated and laid out in advance, and by means of the mechanical movements regulates and controls absolutely the curve through which the trimmer diamonds pass.

To change the form upon the periphery of the wheel for grinding different types and forms of teeth, the operator simply replaces the controlling form in use with the one desired and retrims the grinding wheel, operations which require but a few minutes.

The foregoing has treated more particularly with the production of gears for use in automobile construction.

The use of these machines for the production of gears for automobile work has been an afterthought. The making of gears for the industrial field from materials which have hitherto been commercially impracticable on account of many difficulties, has been one of the influences in the development of these machines. There are materials from which there can be cast roughly to form gears, which, after being finished by the grinding process outlined, will show easily from five to seven times the life of the ordinary forged and heat-treated gear. The only method by which it has previously been possible to finish the teeth of such cast gears is by hand through the use of emery.

No comment need to be made as to the long step forward which this gear-grinding machine shows in the art.

A Standard Automobile Nomenclature

A PAPER READ AT THE S. A. E. CONVENTION BY F. E. WATTS, MEMBER SOCIETY OF AUTOMOBILE ENGINEERS

THE automobile business has grown far too rapidly for its "dictionary" to keep pace with it. Probably all of us who have helped in the production of detail drawings, in the making of parts in the factory, in sending repairs to agents and owners, or in writing about any of these, have noticed the lack of uniform names for parts and operations, and have wished that we had at command words sure to be understood.

Feeling the needs of such specific works in the conduct of his own business, and judging that others have experienced the same difficulties, the president has asked me to bring the matter before this society in the hope that some steps may be taken looking toward the adoption of a set of standard automobile terms.

Of course, we already have a sort of glossary, but it has grown so rapidly that there are often several names for the same part. For instance, the piece which supports the front wheel is varyingly called "steering pivot," "knuckle," "front wheel spindle," etc. The rod fastening these together is known as "drag-link," "steering-link," "reach-rod," "steering cross-connection," "cross-rod," "tie-rod." As to the motor, we have "wrist-pin," "gudgeon-pin" and "piston-pin" for the same part; while the piece which connects this with the crankshaft is sometimes called the "pitman," though more often known as the "connecting-rod." Scores of similar examples will suggest themselves to the engineer.

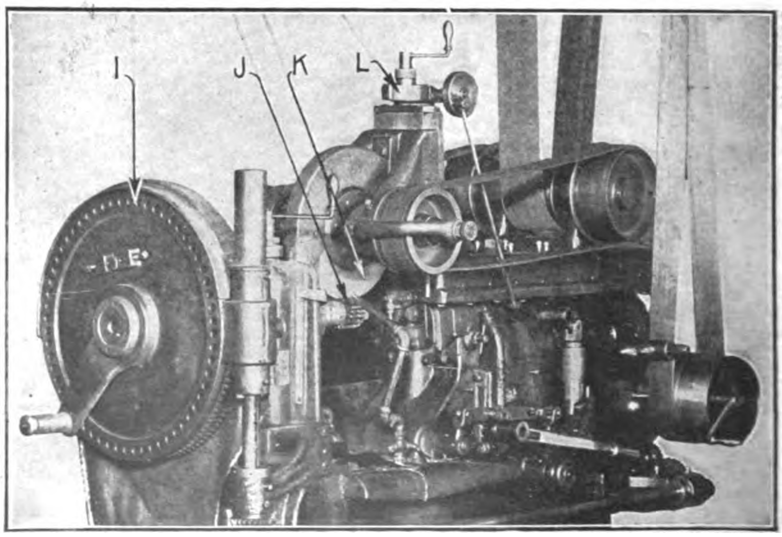

Fig. 3—I, indexing wheel; J, gear to be ground; K, grinding wheel entering gear; L, automatic device for feeding wheel down as it wears away.

We know that words are merely collections of letters, and that most of them have a good many meanings, according to the nature of the sentence they are used in; and, moreover, that there are few words which mean the same thing to a speaker as to his hearers. Nevertheless, it is probably possible to standardize at least the nouns which denote the principal parts of motor cars. We probably would not care to try to standardize the adverbs and adjectives which are applied to the nouns, especially those used in a break-down "forty miles from home."

While the alphabetical order of arrangement of parts is the most natural, there are so many pieces to an automobile that such a list is too long for handy reference, unless it is subdivided. Fortunately, the manner in which cars are assembled naturally provides such divisions, which are used in making up parts lists in all motor car factories.

The following headings are those taken from the price list of repair parts of the Chalmers 30, 1909 model. This parts list was selected because it is unusually complete and also illustrated with sketches of the parts. We will refer to the proposed use of these sketches a little later.

List of Assemblies, or Groups

Accelerator Assembly.
Axle Assembly (Front).
Axle Assembly (Rear).
Propeller-Shaft Assembly.
Body Assembly.
Clutch Assembly.
Dash Miscellany.
Dust-Pan Assembly.
Equipment Miscellany.
Fan Assembly.
Frame Assembly.
Gasoline-Tank Assembly.
Gear-Shift-Guide Assembly.
Hand Lever Assembly.
Hood Miscellany.
Ignition Miscellany.
Motor Assembly (which includes)
  Camshaft Assembly.
  Carbureter Assembly.
  Connecting-rod Assembly.
  Crankcase Assembly.
  Crankshaft Assembly.
  Cylinder Assembly.
  Oil Pump Assembly.
  Timer Assembly.
  Valve Rocker-arm Assembly.
  Water-pump Assembly.
Mudguard and Running-board Miscellany.
Muffler Assembly.
Muffler Cut-out Control Assembly.
Pedal-control Assembly.
Radiator Assembly.
Rock-shaft and Pull-rod Assembly.
Sight-feed Oiler Assembly.
Spark-control Assembly.
Spring Miscellany.
Starting-crank Assembly.
Steering-gear Assembly.
Steering-reach-rod Assembly.
Transmission Unit Assembly.
Transmission-brake Assembly.
Wheel Assembly (Front).
Wheel Assembly (Rear).

The majority of these groups will be found on any gasoline car and the parts included in any of them are not too numerous to handle readily. So if we should take each of these groups and name the principal parts which compose it, the rest would follow easily enough.

Location as Distinction in Terms

The smaller parts, which differ more in the various cars than the larger ones, can be named by a system somewhat as follows: Where there are several parts which are very similar (perhaps performing the same functions on opposite sides of the car), they can often be distinguished by their location in the car. These locations should probably be referred to from the point of view of a person sitting in the car, facing forward. Common words of location are: *Front and rear, right-hand and left-hand, upper and lower*, etc. Usually the smaller parts can be named after the part or parts they are used with. This applies to shafts, bushings, washers, collars, bolts, nuts, studs, pins, pipe-plugs, oil and grease cups and similar small parts. Where several small parts somewhat alike are used with the same large piece, distinguishing prefixes can usually be readily thought of, such as: *Long, short, large, small, round, square, castellated, flanged, lock, retaining, thrust, felt, rubber*, etc. A standard set of such locating and distinguishing terms can probably be developed.

The foregoing suggestions will be of little practical benefit unless some method can be found for collecting and arranging standard terms and bringing them into general use. It has been suggested that a committee be appointed to take this matter in hand, and that it should have enough members that the work can be divided, each covering some small field. The list of standard names should, of course, include at least the principal parts of all kinds of gasoline, electric and steam automobiles.

After these lists shall have been compiled and approved by the society, it is proposed that they shall be printed in the form of a pamphlet, each piece being illustrated by a sketch, so as to make identification certain. A method of arrangement of names and sketches is illustrated in the following "Cylinder Assembly List," taken from the Parts List before referred to; by courtesy of the Chalmers Company.

Possibly volunteers for this work of parts naming can be found among the chief draftsmen of the larger automobile companies; for probably there is no place where standard names for automobile parts will be more appreciated than in the larger drafting-rooms, where new men must be constantly broken in to work according to the necessary rules.

The repair departments of all automobile companies will appreciate this work. For with this "dictionary" in the hands of the engineering department and in the hands of every agent, and of every motor car owner, it is clear to see that an endless amount of confusion will be avoided in the placing and filling of repair orders.

The following should be sufficient to arrest the attention of the society to the matter, which is the only object of this paper. Very likely the work may with advantage be extended so that adopted nomenclature will include a set of definitions of the more common automobile terms and phrases.

Sketch.	*Name.*	*Sketch.*
	CYLINDER ASSEMBLY.	
	Cylinders en bloc. Cylinder priming cock.	
	Inlet manifold. Inlet manifold pipe-plug.	
	Inlet manifold bolt. Inlet manifold bolt lock-washer.

Cork Inserts for Automobile-Making Machinery

PAPER READ BY LAWRENCE WHITCOMB, AT THE DETROIT CONVENTION OF THE SOCIETY OF AUTOMOBILE ENGINEERS.

EVERY element of cost entering into the production of a motor car is an important factor. Therefore, the following in regard to the use of cork inserts is worth consideration.

An economical, efficient and almost indestructible means of eliminating losses in power transmission is a matter of interest.

Leading engineers have repeatedly made the statement in engineering publications that the amount of power lost in mills and factories, between its source and the point of delivery, through the slipping of belts and other friction devices, is far greater than is usually supposed, in some cases running as high as 30 per cent.

Automobile factories in which, owing to the constant growth of the industry, changes and additions are made from time to time, undoubtedly contain many places where there exists such loss of power, which should be eliminated by the purchase of new pulleys or the corking of existing pulleys.

Cork is made up principally of an aggregation of minute air cells, having thin, air-tight, water-tight and very strong walls. If compressed, the resistance to compression continually grows stronger, in a manner more like the resistance of a gas under compression than that of an elastic solid, such as a spring.

It is the elasticity of cork, coupled with its high coefficient of friction and its remarkable ability to withstand heat and wear, which makes it a valuable material for frictional purposes when used under compression as an insert. But it is a peculiarity of cork that while having much elasticity and strength when confined under pressure, it is brittle when not so compressed; and the very grade of cork that proves to be most indestructible when used under compression as inserts, wholly fails, owing to its brittleness and other peculiarities, if used for frictional purposes in its normally expanded and thus weakened condition. It is this fact that has made its successful use for frictional purposes impracticable until the present method of using it under compression was devised.

To obtain this desired compression, sockets are drilled or cast in the face of a pulley, clutch or brake to be thus equipped, and into these sockets are forced corks of a certain grade and of much larger diameter than the sockets themselves. The corks are allowed to dry and are then trimmed and finished so as to have the right amount of projection above the surface of the material surrounding them.

The amount of this projection depends on the nature of the work required of the friction surface. There are, however, two distinct methods of construction.

Consider first the so-called all-cork contact. In this method of construction the sockets are so spaced that the corks occupy a relatively large area and the corks are allowed to protrude above the surrounding surface one-sixteenth of an inch or more, so that they alone come in contact with the opposing surface and transmit all the power. This drive is most efficient and satisfactory where power is transmitted by means of a large area of cork used at light pressure, as is customary on the frictions of looms and similar machinery and in certain types of plate and multiple disc automobile clutches. In this service the pressure and the power transmitted per square inch of cork are so small that there is practically no wear upon the corks, and thousands of automobile and loom clutches thus fitted have been in constant operation for years without requiring repairs.

Second, the so-called composite construction. In this method of construction the corks are allowed to protrude above the surface of the material, in which they are embedded, but one thirty-second of an inch, as in the case of pulleys, automobile clutches, street railway brake-shoes, etc. This method gives an almost indestructible combination surface, of high frictional efficiency and great wearing qualities. At low and medium pressures the corks, with a coefficient of friction of say 0.35, work alone; while at high pressures the inserts are compressed into their sockets, and the surrounding metal, wood or fibre, also comes into engagement to supplement and protect the corks.

Under these conditions the tendency of the cork to yield to compression is greater than its tendency to wear, and when the pressure applied overcomes the rigidity of the cork, the inserts are pressed into their sockets practically flush with the face of the pulley or other friction surface in which they are set, but do not lose any of their efficiency, up to their full frictional limit, since they remain in contact with the opposing surface and present the same face area as before they were compressed. This tendency of cork to submit to compression and thus protect itself from wear is undoubtedly the reason for the excellent wearing qualities of combination surfaces in which the corks occupy a sufficient proportion of the frictional surface to render efficiently the service for which they are installed.

Two important facts to be remembered are that it is the compression of the cork in the sockets which causes them to protrude again above the metal, wood or fibre surface, in which they are embedded, whenever the opposing surface is released; and that the natural physical properties of this material are such that rapid wear is almost impossible.

That cork inserts used under the so-called composite construction will withstand heaviest loads, constant abuse and excessive heat, is shown by their present use in more than 40,000 motor car clutches and by the adoption of this construction by more than sixty automobile manufacturers.

Having treated the matter rather generally, let us now consider how cork inserts are applicable to the automobile manufacturing industry.

Practically all your power is transmitted by means of pulleys driven by belts, and it is generally acknowledged that the capacity of a belt of given dimensions is greater than the capacity of the pulleys over which it runs; therefore, pulleys having high frictional efficiency are most desirable.

The loss that occurs from the slipping of belts reduces product, reaches back to the coal pile and means waste, while on the other hand the failure of certain machines to operate at the desired speed means loss, and in some cases a defective product.

To eliminate these difficulties, pulleys are lagged and relagged, belts are run under excessive tension to the injury of the belt and with an increase in journal friction far beyond economical operating conditions, and belt dressing is purchased—sometimes in large quantities and to an extent that means an appreciable yearly charge to expense account.

If cork inserts are used in pulleys such lagging, excessive belt tension and belt dressing are unnecessary.

That the cork insert pulley exceeds all others in efficiency is shown by tests made by Prof. C. M. Allen, M. S., at the Worcester Polytechnic Institute, a full report of which is too voluminous for this paper, but from which report we copy the following extracts:

"The object of these tests is to compare the relative power-transmitting properties of the various standard pulleys with those of iron and wood pulleys fitted with cork inserts. The standard pulleys used were the smooth iron-face pulley and the ordinary wood pulley.

"All of the pulleys were new to start with, but were in prime running condition when the principal tests were made.

"The belt used was leather and was kept in good running condition during the test.

"The belt speed was about one thousand feet per minute; the revolutions per minute of tested pulley were about two hundred.

"The conditions of atmosphere were such as to give a good variety of tests, being made during the months of July and August.

TABLE OF RESULTS

Load on Dynamometer	Per Cent. Slip Iron with Cork Inserts	Iron
105.0	0.00	1.30
115.0	0.10	1.37
125.0	0.18	1.44
135.0	0.28	1.51
145.5	0.38	1.58
155.0	0.47	1.65
165.0	0.56	1.72
175.0	0.65	1.79
185.0	0.74	1.86
195.0	0.83	1.93
205.0	0.92	2.00
215.0	1.01	2.06
225.0	1.12	2.13
235.0	1.19	2.20
245 0	1.28	2.26
255.0	1.37	2.33
265.0	1.46	2.40
275.0	1.55	2.50
285.0	1.64	2.60
295.0	1.75	2.73
305.0	1.86	2.88
315.0	2.00	3.03
325.0	2.18	3.18

"From the average results of over one hundred tests, the iron pulley with cork inserts at a point of 2 per cent. slip (which is considered allowable in commercial practice) shows a gain in power-transmitting capacity of 51 per cent. over plain iron pulley."

Subsequently to the above reported test it was deemed advisable to make a test of the relative efficiency of several types of small high-speed motor pulleys; and again tests were made by Prof. Allen. The pulleys were all five inches in diameter with three-inch face, and were: (1) Cast-iron, (2) cast-iron with cork inserts, (3) fibre faced with cork inserts.

Appended is the table of results showing the relation between slip in per cent. and horsepower transmitted by the various pulleys tested by Prof. Allen. This table was made up from curves.

Horsepower	Per Cent. Slip Cast-Iron	Cast-Iron and Cork	Fibre and Cork
1	0.23	0.217	0.155
2	0.46	0.43	0.310
3	0.70	0.65	0.465
4	0.95	0.86	0.620
5	1.20	1.085	0.775
6	1.50	1.30	0.930
7	1.85	1.55	1.085
8	2.35	1.80	1.240
9	3.35	2.10	1.395
10		2.43	1.55
11		2.85	1.72
12		3.40	1.90
13			2 12
14			2.35
15			2.70
16			3.18
17			3.95

As certain parties in Lowell, Mass., wished to have a demonstration of the comparative efficiency of cork insert pulleys and pulleys not so equipped, and did not care to rely on the laboratory tests reproduced in part above, it was decided to run a series of tests at the Lowell Textile School, and to invite agents, superintendents, engineers and all other interested parties to participate.

The report in part follows:

"The pulleys tested were all eighteen inches in diameter, six inches face, and were of the following types:

(A) Wood-rim pulley.
(B) Wood-rim pulley, with cork inserts.
(C) Wood-rim pulley, lagged with leather.
(D) Steel pulley.

"The initial belt speed in all tests was about 1,560 feet per minute, and the initial belt tension was approximately 50 pounds per inch of width of belt.

"The comparison of power transmitted at 2 per cent. slip, which is considered a commercial allowance, is given in the first column of the following table:

Type of Pulley	H.P at 2 per cent. Slip	Maximum Horse-power Trans-mitted	Slip in per cent. at Maxi-mum H.P.	Relative Value 2 per cent. Slip
Wood-rim pulley with cork inserts	11.8	13.2	4.6	100 per cent.
Wood-rim pulley, leather lagged	8.7	12.4	4.7	73 "
Steel pulley	8 3	12.7	6.0	70 "
Wood-rim pulley	7.8	9.6	4.3	65 "
Percentage of gain of wood-rim pulley with cork inserts over same without inserts				51 "
Percentage of gain of wood-rim pulley with cork inserts over plain steel pulley without inserts.				42 "
Percentage of gain of wood-rim pulley with cork inserts over leather-lagged pulley without inserts				35 "

"Other tests were made, which would indicate that the percentage of gain for the cork insert pulleys under conditions of less belt tension than that maintained throughout these tests would be even greater than shown above.

"(Signed) G. H. PERKINS"

The several reports from which these quotations are made show that main driving pulleys, receiving pulleys and motor pulleys, and, in fact, all pulleys which may be overloaded or on which slipping may occur will yield better service if equipped with cork inserts than otherwise.

Both wood pulleys and wood-rim iron-arm and hub pulleys now in use may be equipped with cork inserts.

Variation of Current Practice in Anti-Friction Bearings

PAPER READ AT S. A. E. CONVENTION BY D. F. GRAHAM, MEMBER SOCIETY OF AUTOMOBILE ENGINEERS

By anti-friction bearings is meant ball or roller bearings. This paper is not a discussion of the relative merits of bearing types, but a summary of the variation of sizes in use in present models of cars, so far as it has been possible to secure data. An accurate comparison of ball with roller bearings is impossible at the present time, as there is no accepted standard of measure common to both. This paper is therefore largely confined to a comparison of annular ball bearings.

Where a comparison of the cup and cone type is made, the size of the balls only is recorded, and no account is made of the number of balls in each bearing.

In averaging bearings it is essential that a common dimension be secured—the 300 size is used as standard, the 200 sizes reduced to 300 by the subtraction of 2, and the 400 sizes by the addition of 2. This gives a very nearly correct basis for comparison, namely, the load carrying capacity of the bearings.

There has been received from the various parts manufacturers a number of layouts of axles and gear-sets, but in most cases the horsepower allowed for each type was omitted; so no comparison of these could be given.

There is great need of standardizing plain bearings for motors, as to shaft diameter, thickness and length of bearings, etc. At the present time there are about as many sizes as designers.

In the following tables it seemed best to group the cars according to weight, each group including cars of no greater variation than 500 lbs. In the maximum and minimum columns only the bore of the bearing is taken into account, as giving the most important information, viz.: the shaft diameters.

The tables will show a wide variation in bearing sizes for cars of the same weight and power. An analysis of the conditions which surround some of these variations shows that in most cases where a large bearing is used, it is either on account of a peculiar construction, or in an attempt to use a single row annular where others use an annular and thrust or a double row combined thrust and radial. This practice not only makes the housings and all parts larger and heavier, but also costs more.

There are certainly great possibilities from both an engineering and a manufacturing standpoint in the selection of proper bearings for each place in the car, not only as to size, but as to type.

Another distinct advantage arising from the standardizing of bearings would be from the fewer sizes manufactured, the larger stock carried of each size and more rapid filling of rush orders.

GROUP 1—CARS UNDER 1500 LBS.

Three models—Hupp, ABC (Model K), Duryea Buggyaut.

Type of Bearings—Annular, and cup and cone, 1; roller, and cup and cone, 1; cup and cone, 1.

Studies in Aviation Theory and Practice

By MARIUS C. KRARUP.

FACTS of experimental observation in connection with the curvatures of aeroplanes and of propellers are slowly grouping themselves in an orderly array in which the mind perceives a certain correlation betokening the genesis of a physical law, as yet unformulated, relating to thrusts applied against the free atmosphere by means of the surface of solids. The facts referred to are those now well established ones which have been mentioned in previous articles, dealing with the varying efficiency in power application according to the varying angles at which planes are moved through the air and according to the varying degree of concavity with which the pressure surfaces of these so-called planes are formed.

It is of course the great mobility of the air which makes it difficult to apply pressure against it. When it is confined, as in pneumatic apparatus, or when other equally mobile gases, such as steam or the products of a hydrocarbon gas explosion, are confined in the cylinder of an engine, no difficulty is experienced in transmitting pressure with great efficiency by means of the expansion or compression of these gaseous media. Whatever difficulty is met relates to their confinement. Their tendency to escaping has to be watched sedulously. But they respond faithfully to the law of Mariotte, returning a given pressure in inverse proportion to the volume to which they have been compressed. What is sought now, for aid in the development of aviation machines, both as to sustentation and as to propulsion, is a corresponding law relating to thrusts against the atmosphere at liberty.

Material is being gathered at the aerodynamic stations which will eventually permit the scientific establishment of the quantitative relations which must exist with regard to velocities, angles of incidence and shapes of the surfaces with which it is sought to apply thrusts against the atmosphere, but while this material is accumulating many persons in all parts of the world are straining their powers of intuition and of "scientific imagination" to anticipate the final disclosure of the complete law—to anticipate it at least qualitatively. A thesis or theory which has assisted the writer in classifying and understanding the facts recorded by various experimenters, and which has served to reconcile them with other observed facts relating to explosions, tornadoes, parachutes, boomerangs, baseball curves and certain sleight-of-hand tricks with cards, all of which phenomena are more or less intimately related to questions of thrusts against the free atmosphere, may perhaps be expressed as follows:

The free atmosphere opposes a resistance to displacement which is in inverse ratio to the density of the displacing body and in direct ratio to the squared velocity of the latter.

According to this theory the efficiency of a thrust applied by means of the surface of a solid and rigid body must depend upon the interposition of a body of more or less securely entrained air between this body and the atmosphere, and the question of angles of incidence and shapes (curvatures) is resolved into a new question as to what angles and what shapes will result in the formation of the most suitable body of entrained air acting as an efficiency-producer between the rigid surface and the highly mobile free atmosphere. Further, the most suitable body of such air should be one in which the gradation of compression, extending from the solid surface toward the atmosphere and determined by shapes, angles and velocities, reaches from a degree of density against which the solid surface can act with efficiency through successive stages to a lower degree of density, approaching that of the atmosphere itself, and of which these outer layers, being adapted to act against the atmosphere, assume the most favorable, presumably the flattest, form, most nearly parallel with the main extension of the pressure surface of the displacing body.

With regard to the direction of the resistance against displacement, it may perhaps be posited that it must be radial to the formation of entrained air, or extending in converging lines from the least compressed toward the most compressed portions of the same. This assumption would go far to explain the shifting of the centers of pressure under aeroplanes which occurs with changes of angles and speeds. The disastrous action of eddies in the atmosphere, which must be supposed to be formations of a rotary character and comprising layers of air of varying density, also seems to be brought into correlation with other facts by this theory.

In the case of aeroplane action it is well understood that the downward or sustentation thrust under favorable conditions greatly exceeds in lifting power the power of the propulsive thrust which causes it, and this has been considered inexplicable under the known physical laws. Assuming, however, under this theory, that the propulsion of the plane at a suitable angle merely causes the air which is in the path of the plane to arrange itself in a succession of what might be called aerial rollers or sliding blocks, which are hindered in escaping rearward by the lowered rear edge of the plane and downward by the action of the law here tentatively and provisionally formulated, it becomes evident that there is no more reason for demanding a power equal to gravitation for sustaining the moving machine than there is for demanding a power equal to sustaining the weight of an automobile for the purpose of moving the automobile over a road surface.

A paraphrasing of the theory makes this even plainer. Instead of speaking of the resistance of the air to displacement as being conditioned by the density and velocity of the displacing body (of which the entrained air is made to form a part, though one constantly renewed), one may formulate the theory with reference to the speed of displacement. It would then be as follows: **Free atmosphere yields to displacement with a speed directly proportionate to the density of the displacing agent and inversely proportionate to the speed of the latter.**

Now, when the aeroplane is propelled, skin friction causes the adjacent air strata under the plane to roll, in a manner analogous to that of wave formation in the ocean, and the shapes and dimensions of these rolling waves will be determined by the skin friction with the plane, by the intermolecular friction of air and by the chances for escape under the rear edge of the plane (which are again determined by the tilt, shape and speed of the plane). But the mobility and elasticity of air will cause the waves or rolls to form in layers of increasing density toward the axis of each wave, while many minor waves will form a large one as in the ocean, and the forward pressure of the moving plane will flatten and condense the waves on the side from which pressure is received. Assuming now, in accordance with the theory, that the air of a given degree of compression cannot displace air of the next lower degree of compression at more than a certain low speed, and that the velocity of the plane further reduces the speed at which one layer can displace another, it is readily perceived that the plane as a whole simply follows the lines of smallest resistance when it glides forward over the air rollers rather than dropping. No laws of gravitation are violated and no mystery is created, if a law such as formulated, or similar, with regard to the action of one body of air against another, one gas against another, is assumed to exist.

By applying this theory intuitively to all the various phenomena of aviation, the relations between flat and curved, narrow and wide, smooth and rough, flabby and taut planes seem to take on new significance. The accidents seem only natural, and even the somewhat incomprehensible contention of experimenters that a thick front edge reduces resistance to propulsion and increases sustentation begins to look perfectly reasonable—for the kind of planes for which they have found it true.

Digest Along Technical Lines for the Engineer

Quick identification of iron and steel materials by means of an emery wheel is the subject on which Erhard Fuchs of Saronno imparts some information more definite than that which is commonly offered. The writer stepped into a position in which he had to make the best of a lot of old steel material lying around the place unidentified as to analysis, price and origin. Trying the method proposed by Max Bermann (and also known in United States) of recognizing each steel by the sparks it emits when ground with an emery wheel, he found it at first difficult to distinguish the various spark figures, but after a little practice the eye grew accustomed to look for the isolated sparks rather than for the densest bunch of them and then it became easy to tell the typical lines resulting from a certain grade or composition of steel. It is advisable to cut off samples of known composition and use them for comparison. Any emery wheel may be used, but in the various trials it should always be of the same grain and hardness, and the wheel should be operated at normal speed, such as 25 to 30 meters per second. It is the metal torn from the sample which forms the spark, as the emery torn off does not reach red heat.

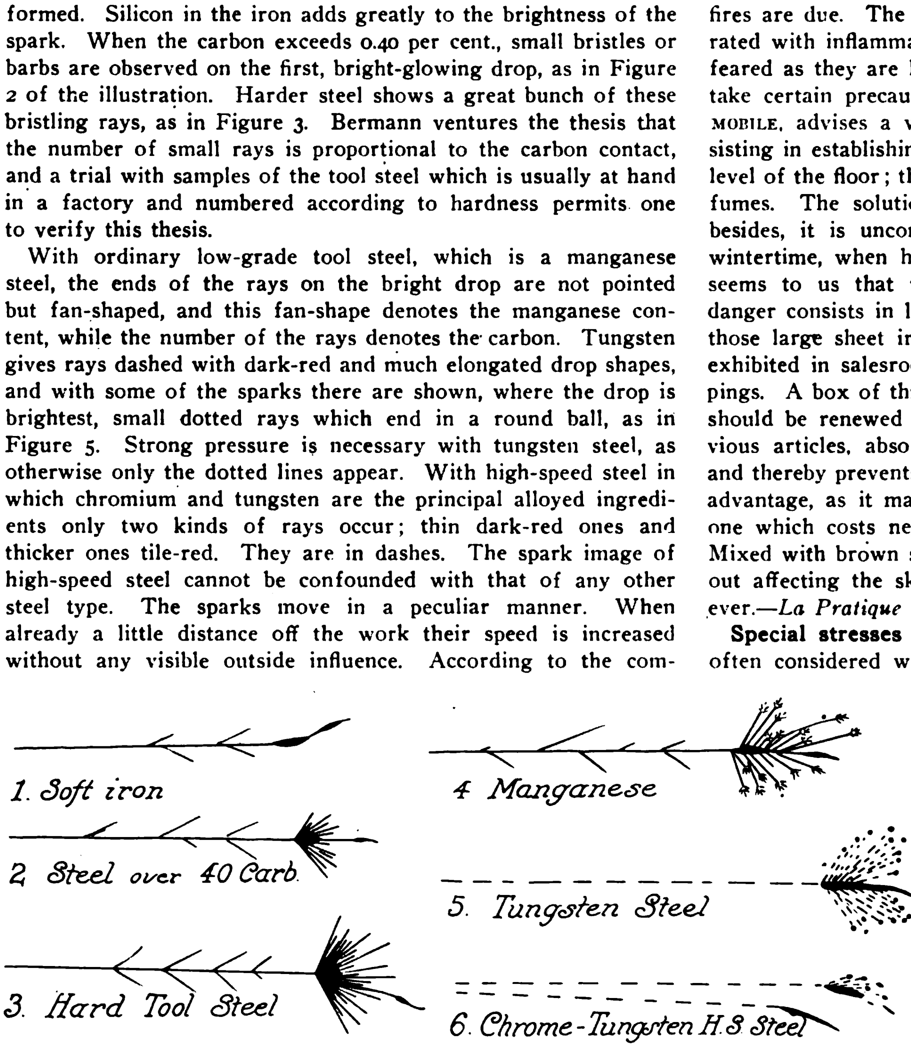
With soft iron, the spark forms a straight line whose end is shaped as an elongated drop which glows very brightly, and immediately in advance of it a smaller drop of dark red is formed. Silicon in the iron adds greatly to the brightness of the spark. When the carbon exceeds 0.40 per cent., small bristles or barbs are observed on the first, bright-glowing drop, as in Figure 2 of the illustration. Harder steel shows a great bunch of these bristling rays, as in Figure 3. Bermann ventures the thesis that the number of small rays is proportional to the carbon contact, and a trial with samples of the tool steel which is usually at hand in a factory and numbered according to hardness permits one to verify this thesis.

With ordinary low-grade tool steel, which is a manganese steel, the ends of the rays on the bright drop are not pointed but fan-shaped, and this fan-shape denotes the manganese content, while the number of the rays denotes the carbon. Tungsten gives rays dashed with dark-red and much elongated drop shapes, and with some of the sparks there are shown, where the drop is brightest, small dotted rays which end in a round ball, as in Figure 5. Strong pressure is necessary with tungsten steel, as otherwise only the dotted lines appear. With high-speed steel in which chromium and tungsten are the principal alloyed ingredients only two kinds of rays occur; thin dark-red ones and thicker ones tile-red. They are in dashes. The spark image of high-speed steel cannot be confounded with that of any other steel type. The sparks move in a peculiar manner. When already a little distance off the work their speed is increased without any visible outside influence. According to the composition of the high-speed steel other rays occur, presumably in correspondence with the contents of titanium, molybdenum or vanadium. By high pressure, the little thin dotted dark-red rays with ball-ends appear now and then.

Cementation steel shows the same image as manganese steel (this seems curious), and from under the hardened surface the same as iron. Cast-iron shows different images, according to its composition, the carbon and the manganese showing as before mentioned. A large number of grey iron samples from different makers gave as many somewhat differing spark figures, but the composition of each was not known. The brightness of the rays varied from dark-red to white and should prove one of the distinguishing means. Many applications of this ready test method should be possible. Old tools of unknown steel may be annealed, worked over and tempered at the right heat. Mixed and unmarked steel may at once be employed for its purpose. Cast pieces obtained in the trade may be compared with analyzed samples. The author expresses a desire that many others will step in and complete his observations.—*Werkstatts-Technik*, May.

If there is a pit under the vehicle in the garage, the danger of fire is no less great, says the author speaking of those accumulations of gasoline in gaseous form to which most garage fires are due. The soil and sides of the pit finally become saturated with inflammable products which are so much more to be feared as they are less in evidence. It is therefore necessary to take certain precautions. Our American colleague, The Automobile, advises a very judicious but rather costly method consisting in establishing a series of air vents in the walls along the level of the floor; there will then be no stagnation of inflammable fumes. The solution is elegant, but, as said, it is costly and, besides, it is uncomfortable for the feet of the mechanic, in wintertime, when he does the daily chores of the machine. It seems to us that the most practical means for avoiding the danger consists in leaving permanently under the vehicle one of those large sheet iron boxes which are used under automobiles exhibited in salesrooms to avoid soiling the floor with oil drippings. A box of this kind should be filled with sawdust and this should be renewed every day. Sawdust, as referred to in previous articles, absorbs a very considerable volume of gasoline and thereby prevents its evaporation. It offers moreover another advantage, as it makes an excellent soap for the mechanic and one which costs next to nothing and does not ruin the hands. Mixed with brown soap it removes grease from the hands, without affecting the skin, better than any other substance whatsoever.—*La Pratique Automobile*, July 10.

Special stresses caused by the use of gyroscopes are not often considered when it is proposed to employ gyroscopic devices for the balancing of automobiles or aviation machines. But light on this subject comes from unexpected sources and shows incidentally, with special reference to aeroplanes, that any attempt to endow them with a high degree of automatic stability, by gyroscopes or any other means, would be accompanied by strains upon the slender materials of these structures which are now obviated through their very mobility in and with the atmosphere. Speaking of the various means proposed for avoiding seasickness by reducing the pitching and rolling of vessels, the author in this case calls attention to experiments made with gyroscopes in British torpedo boats, not for



Typical lines in sparks drawn from various sorts of steel with an emery wheel—the colors are stated in the text avoiding seasickness, but to enable the gunners to point their deadly ordnance with more unfailing precision than is possible when the sea tosses the ship from side to side. The results, he records, were deplorable. The rolling was diminished, to be sure, but the yielding of the vessel to the waves was so much restricted that the latter broke with extreme violence against its shell and threatened to destroy it. It was considered useless to continue the experiments.—*Omnia,* July 2.

The designer's work is the basis on which the buyer and the business manager must work out their economies. They can seldom add anything to the value of his work, though they are in position to detract from it. Every error of judgment on the part of the designing engineer is most likely to be found in the finished product, while some of the virtues of his conception may have disappeared. The fault lies usually in lack of commercial and producer sense with the designer, but frequently it lies in the vagueness of the problem which he has been asked to work out. He is wanted to produce a certain type of construction "as cheaply as possible," while there should be given him a definite limit in mark and pfennig. His dormant economical sense does not wake up until the problem is clothed in exact figures. A simple matter, such as changing a three-speed transmission into a four-speed transmission, becomes much more interesting to the designer when the extra cost of production involved in the change is limited in advance to a scant sum, say 100 mark. It is true that the means for calculation will usually be accessible only to the designer in chief, and it will remain for him to instruct his draughtsmen in the most practical manner. The work of both will gain in depth, to themselves, and in utility. Working closely to a fixed budget is, moreover, nowadays a method outright necessary for commercial self-preservation. The horn of plenty no longer hangs over the automobile industry, in the sense that novelty, as such, may be presumed to compensate for the expenses due to lack of experience and expensive trials of new devices. There must be profits everywhere. And some decided changes in methods are necessary if the spirit of economy shall find satisfaction without deterioration of the products. It must be admitted that heretofore the decisions of husbandry have been more generous than just. Ignorance of the forces and stresses involved and general lack of experience caused the admission of high-priced materials in many instances when its adoption would not be justifiable to-day. Sometimes it was timidity and indecision which promised safe results with the expensive materials. And often it was reserved for the nickel-chrome steel at 1 1-2 mark per kilogram to cover up all sins of construction, and where the costly customer had once found lodgment it was always difficult to unseat him, always a matter of scrupulous hesitation. Few wish to retrograde in materials. For this reason the slowly rising new firms are as a rule working on a more rational economical basis than those who shared the blessings of the cornucopia period.

Taking bar material as an example, there mav be differentiated between the following groups, among which the normal open-hearth (Siemens-Martin) steel at 15 to 16 mark per 100 kilogram may be considered as the unit value.

Tensile strength per square millimeter	Elongation		Price Scale
1. Open hearth steel, 40 kg.	28%	Casehardening material	1
2. Open hearth steel, 45 kg.	22%	Forging steel	1
3. Open hearth steel, 50 kg.	15%	Tempers by quenching	1
4. Open hearth steel, 55 kg.	25%	Casehardening material	1 1-2
5. Open hearth steel, 60 kg.	25%	Casehardening material	2 1-2—3
6. Nickel steel, 75 kg.	20%	Tempers by quenching	3 1-2—4
7. Nickel-chrome steel, 80 kg.	18%	Casehardening material	6
8. Nickel-chrome steel, 95 kg.	15%	Casehardening material	8
9. Nickel-chrome steel, 110 kg.	8%		10

This makes nine different qualities to work with, and the first impression of this fact is deterring. The subdivisions are, however, justified, even at first glance, by the great price difference of the last material, which costs ten times as much as the first. This expensive material cannot be quite dispensed with for good automobiles, but it is of course advisable, wherever this material can be spared, to fall back upon a cheaper one, and on this basis even slight variations in the grades bring important economies. A bar of 50 millimeters diameter weighs about 15 kilograms per running meter. The difference in price by going from No. 9 to No. 8 involves two steps in price or 30 pfennig per kilogram. For one meter of material there is already 4.50 mark saved, and by choosing No. 7 the saving reaches 9 mark for one piece in the construction. In many instances attempts at economy of this order fail only because there are not enough intermediate grades, while it is not feasible to fall back as far as to No. 5. The lack of intermediate grades has been the rule until recent years. The material jumped from No. 4 to No. 8, and this fact conditioned a qualitative difference between the high-grade and the low-grade car. But to-day the steel mills furnish materials at prices from 0.50 to 0.80 mark of very excellent medium quality. With these on hand, the use for general construction of the top notch quality, which is intended only for special purposes, is sheer waste. The number of grades can therefore not be reduced without notable industrial losses. (The author's reasoning can of course not be properly applied to American industrial conditions without considerable modifications, in which the position of the partsmaker and the cost and difficulties in getting proper casehardening and heat-treatment for a large number of different kinds of steel in one factory are among the factors to be considered.)

Another factor in economy is frequently ignored. Many designers are still fired with an exaggerated ambition for light weight and sacrifice considerable differences in price for slight gains in this respect. It has become possible to-day, by reason of the developments of the foundry technic and the processes of mass manufacture, to build very light by the employment of tubular and pressed-steel parts and without any use of expensive materials. It is quite conceivable in some instances to change from No. 8 to No. 1, by considering elements which have been carried into new constructions year after year without new examination as to their fitness under changed industrial conditions. Let us consider a camshaft of 18 millimeters diameter, material No. 8. I use instead material No. 4, price 1 1-2. The strength is perhaps 30 per cent. smaller, so that I must choose a larger dimension. I go to 25 millimeters diameter. That makes the rigidity of the new shaft 1534 as against 572.6 for the old, so that safety no doubt is taken care of (with all allowance for fatigue due to alternation of stresses). The increase in weight amounts to 1.998 kilograms per meter. The saving in cost comes to 97 pfennig per kilogram, and, as the size of the cams renders integral cams desirable, the weight to be considered is that of a bar 50 millimeters in diameter and one meter long, which weighs 15 kilograms; cost saving 14.55 mark. By this saving the increase of 2 kilograms in weight should be justified, especially as it may be offset at other points. For example, a forged step bracket weighs about 2 1-2 kilograms, while a tubular one or one made of pressed sheet steel can be produced at a weight of 1 1-2 kilograms each, which for four brackets means a weight saving of 6 kilograms, aside from the price saving on the brackets. It is easily seen how fruitful a systematic examination of the possibilities extending to every piece of the whole construction may become, particularly if shared in by both the designer and the business manager or producing engineer. With these possibilities properly exploited, an economical decision at one point will frequently lead to an outright improvement in the whole construction. The saving safely effected at one point permits one to spend a little money at some other point which may have proved itself of doubtful security in practice. Out of the 14.55 mark saved on the camshaft, 4.55 mark, say, may be employed for such a purpose, and yet a saving may be recorded on the whole. The general rule of proceeding at every step with a specific examination of the possibilities applies of course to all materials in a car and not only to the question of adoption or non-adoption of the extra high-priced steels. Too much attention cannot be given to the fact, almost forgotten in some circles, that "common steel" after all offers tensile strengths as high as 50 kilograms per square millimeter with an elongation of 20 per cent.—From unfinished article by Diplom-Ingenieur N. Stern in *Der Motorwagen,* June 30.

The Carrying of Tools, Spare Tires and Supplies

EXTRACTS FROM PAPER READ AT S. A. E. CONVENTION BY H. H. BROWN, MEMBER SOCIETY OF AUTOMOBILE ENGINEERS.

Cleanliness, convenience and economy demand that there be a radical change from the present practice of carrying lubricating oil, tools, spark plugs, spare tires, etc. The author points out several practical methods of so doing which the autoist could follow with advantage.

WHILE it may seem to some that the consideration of the matter of carrying tools, tires and other accessories and supplies on a machine are beneath the notice of an engineer or designer, the subject is one which means a good deal to the comfort and convenience of both the passenger and driver. The designer should, in the course of time, overcome all of the weak points of the motor car. In the meantime, repairs of one kind or another must be made on the road. Than the engineer no one is in a better position to know what tools are most suitable for these repairs, and to state what shall be the outfit of the car in this respect, and to him this paper is particularly addressed.

Even granting that any car in question is perfect, yet the puncture fiend is always likely to be with us, and spark plugs will occasionally go out of business. Our prominent designers are, above all, practical men, having perfected their designs by good, thorough road try-outs. During this work, doubtless, many little ideas which would greatly minimize the time taken for a roadside repair have come to them, only to be put aside in the rush of more important details.

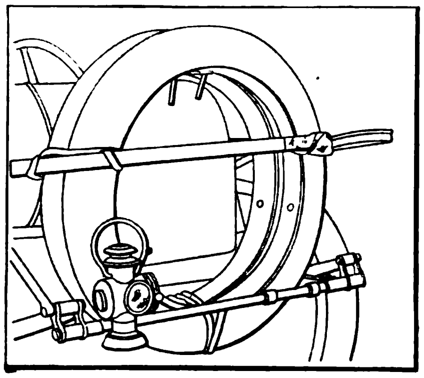


Fig. 1—Demountable-rim carrier on Alco car in 1909 Vanderbilt Cup race

One point that might easily be improved is the method of carrying lubricants. It is an open question whether there is nowadays any necessity of carrying a reserve supply of lubricants at all, other than that which is carried in the squirt-can for immediate use. However, on a long tour, while well-equipped garages at which oil of a good quality may be had are now available almost everywhere, a driver cannot be blamed for liking to stick to a brand of engine lubricating oil in which he has confidence. Therefore, a reserve supply of a gallon is a good thing to fall back on in case a particular brand is not available.

No particular place seems to have been chosen by either makers or users for carrying this reserve supply. The action of oil on rubber needs no comment. Oil cans are almost certain at some time to leak; or, if they do not, in pouring the oil to the motor or squirt-can, some of it will almost invariably slop over, and the chances are strongly against the can being wiped perfectly dry before being replaced in whatever storage place is assigned to it.

From this point of view the tool box on the running board is not so bad a place in which to carry this oil reserve. But one does not care to get the hands more or less covered with oil, whenever a tool is required for some simple adjustment such as removing a spark plug. A step in the right direction was made by a well-known dealer in oils. This maker provided, free to consumers, a little bracket, complete with strap, which could be affixed to the running board. Even if the can should spring a leak, the greatest damage that could result would be a slippery running board; and a liberal dose of sand or dust would easily remedy this fault.

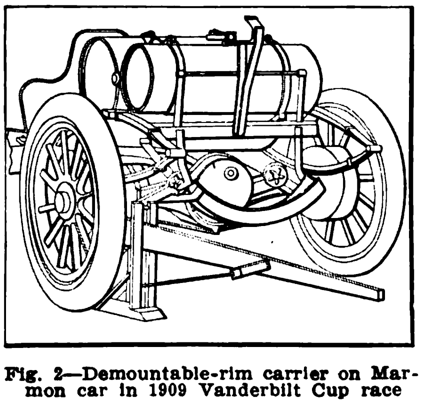

Fig. 2—Demountable-rim carrier on Marmon car in 1909 Vanderbilt Cup race

However, the best place for carrying the supply of reserve motor lubricant is either under the motor bonnet or under the floor boards. In either of these positions it would be near the place of use, would occupy room practically available for no other purpose, and in event of leakage, could do no damage. Of course, it might in some cases be necessary for the maker to provide a can of a special form, and with suitable brackets and fastenings, for holding the same securely in position.

The position and method of carrying tools should be such as to be of the greatest convenience to the driver and of the least annoyance to passengers and others when it is necessary to get at the tools, etc.

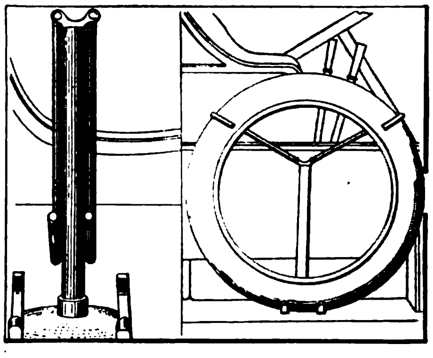

Fig. 5—G. P. M. demountable-rim carrier

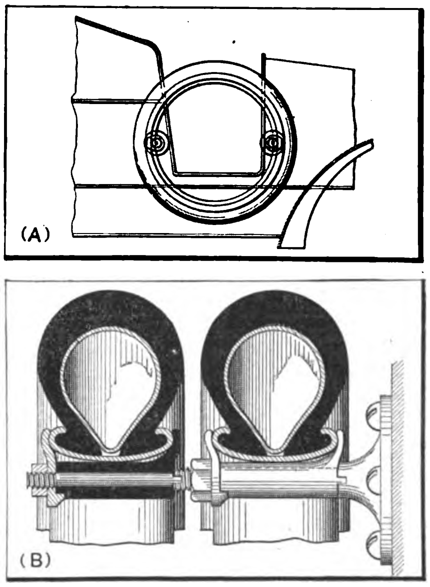
Following this principle to its logical conclusion, the best place, if both places above indicated were equally available for carrying the lubricant, would be under the bonnet, out of sight and yet accessible.

For carrying tools the most satisfactory method, when all classes of cars are considered, is in a tool box on the running board. A box formed under the front seat is from many viewpoints an equally desirable place; but in a touring car which employs gravity feed this position is precluded, as it is desirable not to curtail the dimensions of the gasoline tank in order that the distances that one can travel on a filling of gasoline should be as large as possible. The back seat space may be made available for carrying tools and supplies without inconvenience to the rear seat occupants by means of an outside, side or rear door. However, this method has the drawback that things are much more liable to get lost, owing to either theft or leaving the door insecurely fastened.

One of the best methods of carrying tools is in a tray (or trays) having depressions for each individual tool. An experienced driver or mechanic knows in advance pretty nearly what tools are required for a particular job. With the tray system no time is lost looking for them. Then, again, when the job is done, a glance will show whether any tool which may have been left by the roadside is missing, and the same glance will tell by the shape of the depression just what tool it is that is missing. The only thing that can be said against this method is that it wastes considerable room and is, perhaps, somewhat expensive. Another method is the provision of a roll leather kit, with places for each tool. This method has the advantage that all tools can be carried to the vicinity of the job in question, and that a much smaller space is occupied by the tools as a whole. However, much more time will be occupied in getting out and putting away the tools, which are much more likely to get lost than in the former method.

One point seems to have been given very little thought by the makers: the methods of carrying spark plugs. Many plug makers provide secure mailing cases. As long as a plug is kept in one of these receptacles it matters little how or where it is carried. These receptacles, however, are bound to get lost or misplaced. One good scheme is that a wooden or metal block, threaded for the reception of the plugs, be secured to some part of the machine, in the interior of the tool box, or even under the bonnet. For instance, there might be provided on each cylinder a clip, into which a spark plug could be screwed. This would then act at the same time as a holder, in case one wished to test the spare plug or to test the plug in the cylinder by the method of "parallel gaps."



Figs. 3A and 3B—Demountable-rim carrier, support being applied directly to rim

It is probable that the matter of tire-tool equipment is the one in which American manufacturers have been remiss. The sole tire repair equipment as regards tools until recently was a pump, sometimes of more or less doubtful utility; two plain, straight flat tire-irons, a jack, which was generally too tall to place under the axle when the tire was deflated, and a box which contained a small tube of cement, some minute rubber patches and valve parts. While one can, on a pinch, get along with plain tire irons, yet to handle a clincher tire with facility others are desirable. The number and variety of these are legion, and most of them are good when once the proper method of handling is understood; but some appeal to certain users.

No experienced motorist will think of taking a trip of any length without spare tubes, nor will he rely on a cemented patch, unless he is forced to by stern necessity. Spare tubes should form part of the equipment of all experienced motorists. Careful driving, care and inspection of a modern car will make one practically immune from roadside stops, other than those due to tire troubles, against which no amount of care can entirely guard. The inconvenience of these troubles should be reduced to a minimum. One of the first things to effect this is to make all appliances likely to be needed readily accessible.

For all classes of cars the most convenient place to carry the extra inner tubes is probably the tool box on the running board. If some of the tools and supplies less likely to be used are arranged for in other places than the running board box, then room can be made for spare tubes in the tool box without greatly increasing its size, if at all. In the case of a town car, used as such, even with gravity feed gasoline system, the amount of gasoline needed is so limited as to allow of ample storage space for all tire tools and spare tubes under the front seat. The tire trunk is also a good solution of the spare tube storage space problem.

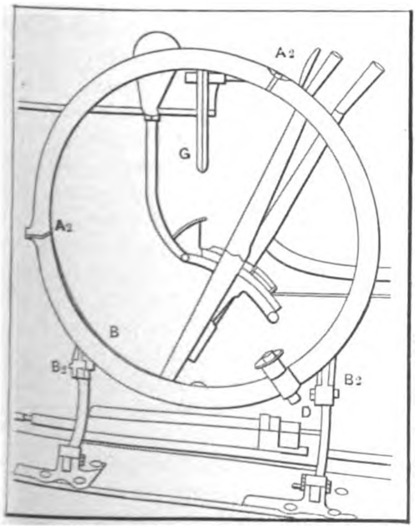


Fig. 4—Dunlop demountable-rim carrier. Pins A_2 and D on outer aluminum ring casting, support rim. Inner casting B is held to running-board by swing brackets B_2, B_2, and to body by shorter swing link G

The introduction of the demountable rim has reduced the number of tools needed on the road for tire troubles to two: the wrench, brace, or key, used in securing the rim to the wheel, and the jack. It is probable that an owner who has had demountable rims fitted to his car will, on getting his first puncture, meet with a good deal of disappointment as to the time required to effect the change. This is owing a good deal to the accounts he has heard of changes being made during races in between thirty and forty seconds.

In the case of a touring car, getting out and putting away tools, especially if they are kept in a locked tool box, will easily take a minute. There is generally one man, only, available for the work, and while he may have a pretty good general idea how to do the job, he has given very little thought as to the best sequence of operations; hence a further waste of time. It may, therefore, be laid down that with identically the same equipment a driver is doing well if a tire change is accomplished in anything like double the time taken by the change on a racing car.

On the Alco, driven by Grant in the last Vanderbilt Race, two tires were carried in the rear in a sort of frame or basket, each within a separate compartment of the frame (Fig. 1) and so arranged that no straps were needed, a tire when inflated fitting its compartment snugly. It is doubtful, however, if this method would be a good one for regular pleasure conditions.

A rather good method was employed on some of the Marmon cars; in this case one tire only being carried. A sort of trough being bent to the same radius as the tire served as a support, the upper part of the tire resting in a shallow Y-shaped piece, and being held securely therein by a single strap. (Fig. 2). This form of carrier has the advantages that it serves equally well to carry without movement an inflated or deflated tire, and requires little time for strapping and unstrapping.

Very little seems to have been done in this country toward the design of a carrier supporting the spares by the rim, although at least two patents have been granted on carriers which use this method. (Figs. 3A and 3B—McMurtry patent). The great advantage of this method lies in the fact that chafing of the tire is entirely eliminated. Figure 4 shows a device of this type marketed by the English Dunlop Company. This device will also serve as a holder while changing tubes, shoes, etc.

Two examples of what may be called automatic or semi-automatic demountable rim carriers are given. Figure 5 shows the G. P. M., in which two hooked arms are pulled down on to the tire by a spring concealed in an upright column.

Figure 6 shows the Rotax, another English device, in which the tire is retained in position solely by its weight. The action will be clear from the cut.

The Pyrometer, Its Development and Use

By WM. H. BRISTOL

Opens with early history of pyrometers of the various types; discusses the laboratory side of the situation; refers to the Le Chatelier pyrometer as an instrument of precision for calibrating purposes; points out the necessity of a more sturdy instrument for practical work; describes the Bristol type of instrument for the purpose.

IN scientific research in the laboratories of manufacturing plants, and in connection with every-day operations in a factory where heat is employed, as in the treatment of steels for parts of an automobile, pyrometers have come to be considered a necessity. In the heat treatment of alloy steels in particular the range of temperature permissible is very narrow, and it is impossible to judge the small ranges of temperature required by the eye. A sensitive and accurate pyrometer, by means of which the product may be duplicated with certainty from day to day, is of the utmost importance. At a large automobile plant which the writer recently visited, the head of the hardening department said he would be unable to do his work without a pyrometer, it being to him what the mariner's compass is to a sea captain.

A man with no experience was placed in charge of a large hardening room with pyrometers connected to the different furnaces, and given directions for using the pyrometers in the treating of steels for the important parts of automobiles. For over a year this inexperienced man has successfully turned out material which has passed through his department.

With pyrometers it is possible to determine by experiment the proper method and temperatures for the working of a particular product to obtain the best results, and afterwards it is a simple matter to duplicate the results.

The thermo-electric pyrometer is the one which is the most generally adopted and in use at the present time, and as the author has made a special study of the development of this particular type of pyrometer, special importance will be given to these pyrometers in this paper.

Before describing and taking up the characteristic features of the thermo-electric pyrometer, brief sketches of different types of pyrometers will be given.

The first practical pyrometer was devised in 1782 by Wedgwood, an English potter, for use in operating his kilns. He depended upon the contraction of clay at high temperatures for his measurements.

In the ceramic industry Seger cones are used, having various degrees of fusibility. There is a tendency of these cones to curl over when certain temperatures are reached, but, of course, they are valueless to show if the temperature has fallen back.

Fusion-point pyrometers have been used, making use of the known melting points of different metals and other substances.

Metallic expansion pyrometers have also been developed in which use is made of the actual expansion of the metals, or the differential expansion of two metals fastened together. In this class of instruments, however, the metals take permanent sets and are not reliable.

Heat conduction pyrometers have also been developed, in which a current of water of known temperature flows at a constant rate through a tube placed in a furnace. The increase of the temperature furnishes a means of measuring the temperature of the furnace.

Specific Heat Pyrometer. If a body of metal of a known weight is transferred from the furnace to be tested and plunged into a quantity of water of known weight and temperature, the increase of temperature of the water will depend upon the temperature in the furnace and is a means of measuring the temperature. This type of pyrometer with a copper ball has been used until recently by very large works.

The air or gas pyrometer depends for its operation upon the expansive force of air or gas when heated to the temperature to be measured. This means of temperature measurement is used as a standard at the present time.

The Optical Pyrometer. In one type of the optical pyrometer the temperature is determined by the photometric measurement of radiations from substances heated. Another type of optical pyrometer depends upon the polarization and refraction of light by means of Nicol prisms.

Reprint No. 11 from Bulletin of United States Bureau of Standards, Vol. 1, No. 2, is on "Optical Pyrometry," by C. W. Waidner and G. H. Burgess, of the Bureau of Standards. In this bulletin different optical pyrometers are described and discussed.

Radiation Pyrometers. Pyrometers of this type have been developed recently by Professor Fery, in which the radiated heat from the body is focused upon a small thermocouple by means of a concave mirror. This type of instrument is being introduced commercially and is especially valuable for the measurement of temperatures above 3000 deg. Fahr., where the platinum, platinum-rhodium thermo-electric couples cannot be used. The introduction of electric furnaces makes this type of instrument particularly valuable.

Electric Resistance Pyrometers. This type of pyrometer was first suggested by Sir Wm. Siemens in 1871. He used platinum wire for resistance wound on clay, but it was found that the silica attacked the platinum, making it brittle. In 1887 Professor Callendar worked out a practical form of the resistance pyrometer with platinum resistance wire mounted on mica, and he developed the plan of using the Wheatstone bridge with a compensating lead which has proven of great commercial value for temperature measurements. The Callendar instruments were of the zero type, and depended upon restoring the balance of a Wheatstone bridge by a handle adjusting resistance. Professor Callendar developed a recording instrument which operated by means of two stops to close the circuit of one or another relay, which in turn operated the carriage for the recording pen. The resistance type of pyrometer is accurate and practical for ranges to 1200 deg. Cent. For the measurement of small changes of temperature it is particularly well adapted. In a paper presented at the Scranton meeting of the American Society of Mechanical Engineers in June, 1905, Dr. Howard F. Barnes, of McGill University, described a pyrometer of the resistance type, in which one degree covered a length of 8 inches on the scale, making it possible to estimate to 1-1/1000 of 1 deg. Cent.. In the resistance pyrometer the limit of accuracy depends on the limit to which resistances can be measured. In the resistance pyrometer for measuring high temperatures only platinum can be used for the resistance element, and therefore the parts that are applied to the furnace are expensive. In this type of instrument there are possibilities of error, due to thermo-electric couples being formed at various junctions and to the heating of the resistance wire by the current used to operate the instrument. It is also important that sufficient immersion be made when the temperature is measured, which is not always convenient to obtain. The construction of the resistance coil necessarily occupies appreciable space and, together with the insulation, produces a time lag that must be allowed for. The resistance pyrometer has its particular field of usefulness.

Reprint No. 124 from Bulletin of United States Bureau of Standards, Vol. 6, No. 2, is devoted entirely to the study of platinum resistance thermometry at high temperatures. This bulletin is by C. W. Waidner and G. H. Burgess, of the Bureau of Standards. In addition to the full description of platinum resistance thermometers there is given a list covering several pages of references to articles on the subject.

The Thermo-Electric Pyrometer

This instrument depends for its operation upon the phenomenon that an electric current is produced when the opposite junctions of two dissimilar metals or alloys are of different temperatures. This law of nature was discovered by Seebeck in 1820. The two dissimilar metals or alloys which are thus joined have come to be known as thermo-electric couples. As stated by Le Chatelier in his book entitled "High-Temperature Measurements," Becquerel was the first to make use of the discovery of Seebeck in applying the thermo-electric couple for measuring high temperatures. He used a platinum-palladium couple. Pouillet, in 1836, carried on further researches with thermo-electric couples. Other scientific experimenters have studied and carried on investigations with thermo-electric couples, using a great variety of metals and alloys to discover a couple which would resist high temperatures, and could be depended upon for constancy for the measurement of such temperatures. It was not until Le Chatelier, after doing a great amount of work with the thermo-electric and optical pyrometers, introduced the thermo-electric couple of platinum, platinum-rhodium that good results were obtained. This couple, which has been most widely used for over twenty years, has come to be recognized as a standard for measurement of temperatures from 300 deg. Cent. to 1600 deg. Cent.

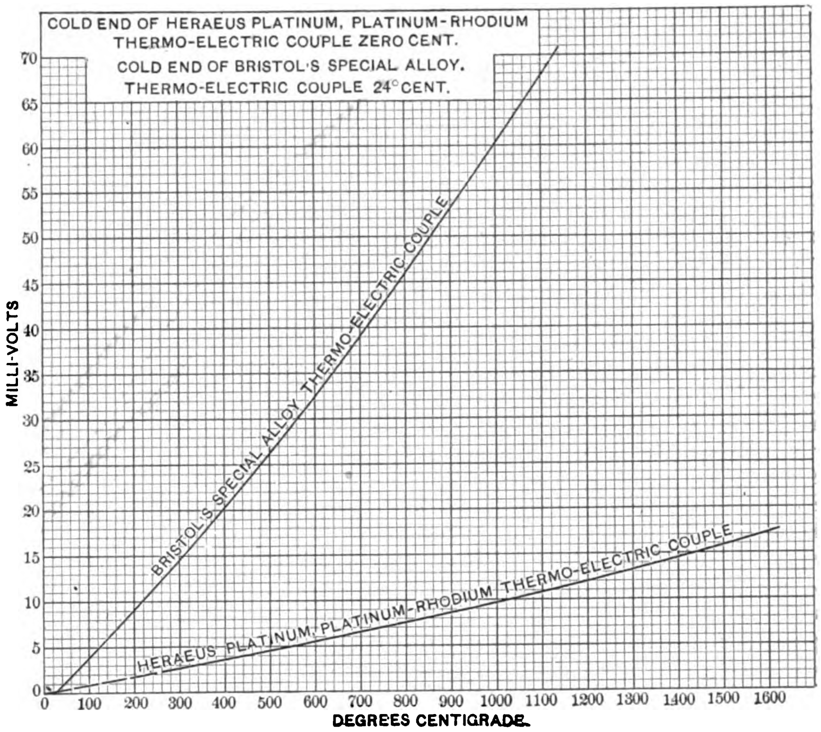

Fig. 1—Pyrometric records of Heraeus and Bristol thermo-electric couple pyrometers, from data given in tables 1 and 2

As thermocouples depend for their operation upon the difference of temperature between the hot and the cold ends, to have a standard basis for comparison, the electromotive force developed by the platinum-rhodium couple is based upon the supposition that the cold end of the couple is maintained at zero Centigrade. The following table No. 1 gives electromotive forces from a standard Heraeus platinum-rhodium couple for different ranges of temperature between 300 deg. Cent. and 1600 deg. Cent.:

TABLE NO. 1

Cold end of Couple at 24 deg. Centigrade	

The relation between the electromotive force and the temperatures is very clearly shown by the lower curve in diagram No. 1, where the ordinates represent millivolts, and the abscissas degrees Centigrade. It will be observed that this curve is not a straight line, and, therefore, it is not possible to make any absolute rule for the correction that will be necessary when the couple is used with the cold end of the junction at any other temperature than zero Centigrade (freezing water). In practice, where the platinum-rhodium couples are employed in industrial operations it is not generally customary to maintain the cold ends at a constant temperature, or zero Centigrade, and, therefore, corrections should be made for the variation in temperature at the cold end of the thermocouple from zero Centigrade. This correction for the platinum-rhodium couple is approximately plus half of the Centigrade temperature of the cold junction for a limited range, and increases to unity as the temperature of the cold end increases.

From the above figures and curve it will be observed that the platinum-rhodium couple produces only a very feeble current, and, therefore, in order to accurately measure the current of electricity produced by the small electromotive forces for the different temperatures over the range, it is necessary to have an extremely delicate and sensitive instrument. The high-resistance suspension type of instrument has been adopted generally, the high resistance being necessary to eliminate the effects of temperature influence upon the resistance of the elements forming the couple, and upon the leads and coils of the galvanometer itself. For laboratory research and for standardization purposes the Le Chatelier platinum, platinum-rhodium couple with a high resistance galvanometer is the most convenient and accurate apparatus for measuring high temperatures. The delicate suspension galvanometer with the platinum-rhodium thermocouple of the Le Chatelier type may, therefore, be considered better suited for laboratory use than for shop service. The platinum wires are very expensive, and they also require expensive insulating tubes. Where the platinum couples are employed in a commercial way, sufficient attention is not given to taking care of the temperatures at the cold ends of the couple, as they are naturally made as short as possible to save expense, and thus the cold end cannot be carried away from the influence of conduction and radiation from the furnace where the temperature is to be measured. It is, of course, possible to provide artificial means for keeping the cold end of the couple at a constant temperature, but this adds expense, and is very troublesome.

To meet the increasing demand for pyrometers for every-day shop use which would be reliable and comparatively inexpensive, taking into consideration both the initial cost and the cost of maintenance, the low resistance type of thermo-electric pyrometer was developed in 1906.

(To be continued.)

Slide, Rotary, and Piston vs. Poppet Valves

By EUGENE P. BATZELL.

This paper was presented at the summer meeting of the Society of Automobile Engineers and is a resumé of the valve situation illustrating the various types in use and proposed, discussing in detail their respective merits. It is pointed out that poppet types of valves are difficult to maintain in noiseless condition and it is the claim of this author that questions of noise are at the bottom of much activity in favor of the elimination of the poppet type of valve.

DESPITE the seeming activity along lines involving other than poppet types of valves the author of this paper has pointed out that but few slide, rotary, and piston types of valves have found favor in practice. He goes on to say: "Still fewer have been subjected to tests. It is easily understood that the published test results of different silent valve motors all appear to be favorable; nevertheless, without gaining the favor of engineering circles and of the general public. The best proof of this is that only few of such valve systems are being built by others than those through whom they originated; and their comparative success is accountable largely to vigorous advertising campaigns. Probably some time will elapse before the silent valve systems will be used extensively, and compete successfully with poppet valves, because the latter are highly developed and reliable.

"On account of lack of dates and information upon the silent valve systems, it would be hard and of little value to discuss the practical lines of their construction. One would be compelled to guess, because the final word will be spoken after the motors have been in public use for a long time. There is, however, a possibility of investigating the subject theoretically, particularly as to motor power. Theoretically deduced results will have to undergo many corrections in practice.

"The discussion will be taken up here mostly as an investigation of valve-opening diagrams, together with their respective intake gas velocities. Let everything be referred to four-cycle single-cylinder motors of five-inch bore and six-inch stroke running at 1000 r.p.m., corresponding to a 1000 feet per minute piston speed. The cam-operated poppet valves only will be discussed, not touching the possibility of their being operated indirectly by some means.

"The rate and duration of opening of a poppet valve depend on the shape and size of the cam, and the type and size of the cam-follower. The most extensively used forms of cam-followers are the roller, the 'V'-shaped, and the flat or mushroom valve lifter foot. The valve-opening diagrams with the roller and the 'V'-shaped valve lifters depend upon the radii of the contact surfaces. Identical diagrams are obtained regardless of whether the cam-base circle or the follower-roller or spindle are made of a certain size, providing the relation between them remains the same. Therefore, only the flat and roller lifters will be considered.

"As to the cams themselves, they can be made in very different shapes. In Fig. 1 are represented three, which will be discussed here, 1 and 2 being designed for use with a roller-lifter and 3 for the flat. They are all inlet cams with same lift (five-sixteenths inch), and are shaped for the same duration of valve opening, namely, 210 degrees of crankshaft movement. The inlet could, for instance, start to open 5 degrees after the upper dead center, and close 35 degrees after the lower dead center, which is fairly good timing for high and medium speed. With roller-lifter cams there is a one-sixty-fourth-inch clearance between the valve stem and the lifter. The cam for the flat lifter is easier to shape with a greater clearance, which is made one-thirty-second inch on the drawing.

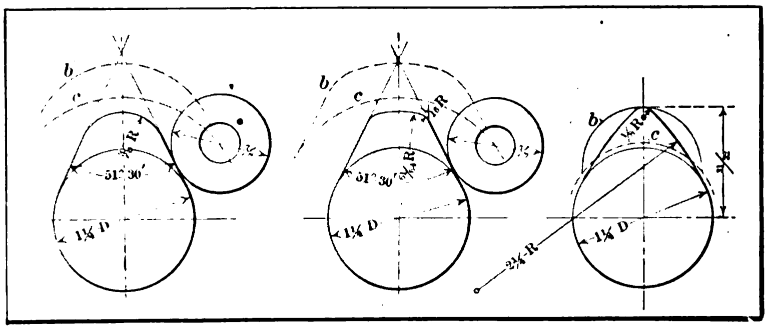

Fig. 1—Inlet cams, with 5-16-inch lift, shaped for 210 degrees opening; 1 and 2 for use with roller-lifter; 3 for flat

"The cam base circles are all 1 1-4 inches in diameter, and the roller is 7-8 inch in diameter. The flat contact surface of the valve lifter is one inch in diameter, and the cam is rounded in such a manner that contact with the edge of the lifter is avoided.

"The top portion of the cam is a single circle tangential to its straight flanks, which latter are determined by the position of the roller and the valve lifter clearance in the usual way; that is, the lines touching the roller and the cam-base circle at the moments when the inlet begins to open and close. The flanks of the cams are determined in the same manner, but the extremity of the cam is formed by an arc concentric with the base circle, and extended until it intersects the flanks. These intersections are rounded into a small radius. On the drawings, Fig. 1, the dotted lines 'b' represent the amount of valve lift. For each angular position of the cam the lift is equal to the distance between lines b and c taken in the direction of the center line of the valve-lifter. For cams 1 and 2 line c is a circle, passing through the center of the roller at the moment of valve opening, and for cam 3 it is the clearance circle.

"The valve lifts obtained in such a manner for different angles between the cam center and the lifter can be plotted against the angles of crank position, thus giving valve-opening diagrams. Such diagrams for the cams of Fig. 1 are reproduced in Fig. 2, and are indicated according to the cam numbers by 1, 2 and 3. They all give the following timing: Inlet opens at 5 degrees after the upper dead center and closes 35 degrees after the lower dead center. However, the area of valve opening at any particular crank position is a more important thing to know than the valve lift. Assuming that the gases flow through the valve opening parallel to the valve seat:

Let,

h = lift of valve in inches;

h_1 = distance between valve seat and face of valve in inches;

d = diameter of orifice below the valve seat in inches;

d_1 = outside diameter of conical valve in inches;

When,

$$S = \pi \times d_1 \times h_1 = \pi\,(d + h_1 \sin^{a})\,h_1$$

or substituting $h_1 = h \cos^{a}$

$$S = \pi\,(d + h \sin^{a} \cos^{a})\,h \cos^{a} \qquad (1)$$

"When the valve seat is flat the area S is proportional to the valve lift h, as then the second part in the parentheses disappears. Flat valve seats are seldom used, however, because they are hard to keep tight; they retard rather than promote the gas flow, making the gas change its direction suddenly, and besides they also become beveled in time. For bevel-seated valves the port area S is a function of the second degree, according to equation (1). However, this area may be considered directly proportional to the valve lift h in this case also, because the squared factor in equation (1) is relatively small and may be neglected. The error thus made is the slighter the smaller the horizontal angle of the valve seat. Assuming, then, that the valve lift and port area are directly proportional, we may also consider curves 1, 2 and 3 of Fig. 2 as representing the variation of this port area with the crank position, and it is only necessary to construct a diagram of the proper scale to get the port opening areas in actual figures. We will suppose that the motors in question have valves of 2 7-16 inches clear diameter, and that the valve-seat has a 30-degree horizontal angle α. As the lift was made 5-16 inch, the maximum valve port area is:

$S_{max} = \pi (2.4375 + .1355) \times .271 = 2.2$ square inches.

"If we make the valve lift of 5-16 inch in Fig. 2 correspond to 2.2 square inches, the scale for the port area curves becomes known, and it is then possible to draw from these diagrams a number of conclusions as to the motor characteristics with the different poppet-valve lifting mechanism.

"As may be seen from Fig. 2, the area enclosed by the curve 3 is slightly larger than that enclosed by curve 2, and these areas are both larger than the area enclosed by curve 1."

The author here introduced an equation involving the momentary valve port area in function of the crank position given by time, went on to state a method of arriving at gas velocity, and utilized the customary equation for piston speed, pointing out, however, that the same is not exact, and that the piston speeds may be found in the curve C, Fig. 2, assuming that the motor is traveling at 1,000 revolutions per minute. The paper deals next with the questions of motor power with different cams.

"Comparing these three curves in Fig. 2, we notice a maximum difference of about 10 per cent. between v_1 and v_2. Moreover, this difference occurs when the inlet openings are near their maximum, and when the gas velocity is much lower than at the beginning of the opening. Therefore, in respect to motor power cam 2 will show no great advantage over cam 1. (Fig. 1.) With slow-running motors, the difference between these cams may be absolutely imperceptible.

"With these cams under the assumed conditions, the inlet gases are strongly choked during the earlier part of the valve opening, and consequently there is considerable vacuum inside the cylinder during this period. This vacuum, besides causing direct loss of motor power, also sucks oil past the piston, which tends to cause carbonization. A point in favor of high intake velocity is a more complete vaporizing and mixing of the gas particles with the air when entering the cylinder. But normal gas velocities should be sufficient for that, so that any increase would be a pure loss.

"The theoretical gas velocity drops much more quickly with cam 3 than with cams 1 and 2, and consequently the intake gases are much less choked with this cam during the early part of the inlet. The difference in velocities with cam 3 and the roller cams, respectively, amounts to 20-30 per cent. during a crank motion of 45 degrees, and, furthermore, the choking effect is proportional to the second power of the gas velocity at least. The quantity of fresh charge admitted to the cylinder during the first half turn of the crank will be considerably greater with valve-lifting mechanism 3, and this will reduce the vacuum inside the cylinder, together with its bad results. This mechanism is decidedly advantageous, except that it requires very strong valve springs, because the first part of the curve of cam lift is very steep.

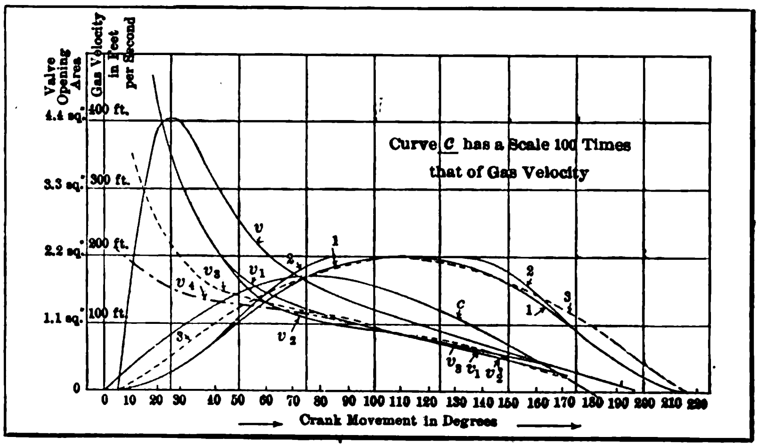

Fig. 2—Valve-opening diagrams of cams shown in Fig. 1

The stronger the valve springs are the more the valve seat and valve mechanism are subjected to wear, and constructions 2 and 3 are particularly disadvantageous because of the great sliding motion of the cam against the lifter. Of course, cams for roller lifters can be shaped to give the same quick opening as cam 3, but the objections to quick opening are then greater.

"With valves of the same weight and the same lift acceleration, the roller-lifter, being heavier than the flat one, requires stronger valve-closing springs. There is but little wear on the faces of cams and rollers due to the roller action, providing they are properly hardened and the springs are strong enough to keep them in contact. Therefore, the wear of them cannot be given here as an objection to strong springs, but the valves coming under action of the stronger springs, and with a quicker motion against their seats, cause more noise and become leaky more often, which is due to increased hammering into the seats of carbon particles.

"In curves v_1, v_2 and v_3 of Fig. 2 it will be noticed that the gas velocity also gradually drops during the period when the valve openings decrease, because of a more rapid decrease in the piston speed. From a velocity of 170 feet per second at the moment of greatest valve opening, the gas velocity drops to about 50 feet per second during the following 60 degrees of crank travel. At the lower dead center the inlet valves still have openings 0.7 square inch (cams 1 and 2) and 1 square inch (cam 3), respectively. The last 10 degrees of crank movement before the dead center need not materially influence the change of gas velocity, and during the following crank movement it cannot be greater than 50 feet per second, as it was at 170 degrees crank position.

(To be continued.)

Coming Events in the Automobiling World

Dec. 1............Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

"APACHES," among America's red men, represented the most unscrupulous and altogether bad Indians of the many tribes which infested the American continent, probably from the days of the mound-builders down to the time when the pressure of the white man produced extermination of all but a few degenerates who put in their time drinking fire-water and gambling.

* * *

QUOTING the New York *Herald* of August 2, this respected newspaper reminds us of the fact that the "Apaches," after having run the gamut in Arizona, took up their abode in Paris, where it was hoped they would remain under the enlightened guidance of the French. As the *Herald* states, "American financiers come in for virulent criticism in the reviews of the Bourse, which Paris newspapers publish at the end of the week. It has become a fashion here of late years to call all malefactors 'Apaches.' You will, therefore, understand the significance of the fact that, in commenting on the battle royal which big interests have been waging in Wall Street at the public's expense, French critics manifest a tendency to dub the leading spirits in it 'Financial Apaches.'"

* * *

ARE "Financial Apaches" trying to take the scalp of the automobile business?

AT the Summer meeting of the Society of Automobile Engineers just concluded, many points of interest were raised and discussed, and a close observer will have reached the conclusion that the attention of the body to some phases of the problem is timely.

* * *

GOOD steel is admitted to be a necessity, but the struggle for quality must await the coming of the time when automobile engineers may be permitted to know how to ask for what they want. For many years steel mills not only fabricated their wares, but they had time to expend in fabricating the literature of the day, to the confusion of their patrons, if not to the exclusion of quality product.

* * *

IF makers of steel were to succeed in packing the conventions, overawing engineers by their presence and a flood of questionable information, they would succeed in perpetuating the literature that has been fastened upon the industry, fostered by those whose interest lies in finding a willing purchaser, made the more so by being drugged to insensibility by statements that may be twisted and distorted until they mean anything that the victim's master dictates.

* * *

PLAINLY speaking, the good that any society can do depends upon the intelligence displayed by its management. The body politic is taught to abide by the decision of its accepted leaders, and to believe that they are acting in the best interests of all concerned. In the case of the Society of Automobile Engineers, should the leaders be swayed by a clique of steel men the body politic would find itself steeped in the dye of poor material, and the makers of foreign automobiles would be free to bid for the better class of trade.

* * *

IT is frequently claimed that foreign automobiles are superior because the material used in them is better than that obtained elsewhere. American makers of automobiles stoutly contend to the contrary, and it is one of the high aims of automobile engineers to justify this contention. In glancing over a daily paper of recent vintage, one of the items read substantially as follows: "The company just placed the largest order for cold-rolled steel that was ever given by any automobile company." If this statement was true, it is highly improbable that this company had any room in its product for anything but cold-rolled steel.

* * *

SPECIFICATIONS are about to be formulated under the auspices of the Society of Automobile Engineers, and a committee on standards is to be given charge of the work. That this committee should be made up of the agents of steel mills is not to be expected, but that the agents of steel mills would like to control the committee is a natural inference.

* * *

AGENTS of steel mills may be divided into two classes: the first admits it, but the second denies the soft impeachment.

Detroit Extends Welcome to the Largest S.A.E. Gathering

(*Continued from page* 178)

Gears Quiet by Grinding." Every automobile engineer appreciates the importance of this question; it is fully understood that gears have to be hard to serve well, and it is remembered that warping is a normal expectation in the hardening process. The gear grinder described by Mr. Ward takes the gears after they are hardened and refashions the teeth so that they conform to the involute with a 14 1-2 degree face angle. Mr. Ward, in response to query, stated that he had a preference for 6 diametral pitch gears and that an allowance of ten thousandths of an inch should be made for grinding, thus demanding the use of gashing cutters suitably sized to afford this allowance. Perhaps one of the most important details brought out in the discussion is represented in the fact that the depth of grinding will not be the same at all points in the diameter, so that the thickness of the case grown in the cementing process must always be sufficient to take care of the eccentricity. There seems to be no way of avoiding this difficulty and it stands to reason that unless the depth of the case is greater than under ordinary conditions there is an excellent chance of realizing "thin ice" at some point in the diameter, due to the grinding process. Quite a number of the members present failed to agree with Mr. Ward when he said that the gear grinders referred to were not to be sold outright by the makers, but that they preferred to do the grinding work for builders of automobiles, claiming that the cost is but slightly increased, all things considered, and that deliveries will undoubtedly be prompt. One member, however, made a rough calculation and was curious to know what might be expected if a company building 30,000 automobiles per annum, with upward of 300,000 gears to be hardened and ground, was to dump them at the door of the gear grinding establishment and ask for a prompt delivery. This one member may not have taken into account the fact that there are a large number of companies in this country, and that more than one of them would be in a postion to order 300,000 gears per annum.

The problem of standardization was given a boost in the right direction by D. F. Graham in his paper entitled "The Variation of Current Practice in Anti-friction Bearings." Mr. Graham's effort has the earmarks of a painstaking research, and in tabular form affords a wide variety of definite information bearing upon present practice. To what extent this effort will further the process of standardization remains to be seen. It is understood that there will be a committee appointed to deal with the process involved, and it is recognized that the committee will scarcely be able to deliberate at once upon all the subjects.

Lawrence W. Whitcomb presented a most comprehensive paper bearing upon the economical side of shop unkeep, having for its basis the elimination of power losses through the use of "cork inserts" in pulleys for the purpose of reducing slippage. It is well understood that there is a considerable loss of power during its transmission by belts running over pulleys and for many years millwrights struggled with the problem unsuccessfully. Cork inserts seem to be efficacious, due to the high coefficient of friction of cork, and to the peculiar fact that this coefficient is not materially reduced by lubricating oil. The paper affords a wide range of exact information and carried conviction sufficiently to abort discussion.

The paper by H. H. Brown, entitled "The Carrying of Tools, Spare Tires and Supplies," was the only one which recognized the necessities of the supporters of the industry in the form of users of automobiles, and while it deals tersely with some nice phases of the situation, it is nevertheless an inadequate tribute to be paid to the American citizens who have made the automobile industry possible. That President Coffin ultimately expects to lead the way to the direct benefits due to purchasers of automobiles, before the campaign is terminated, is quite well appreciated by those who have given the matter more than passing attention. President Coffin, in his opening address, discussed the lines along which the organization may be made of the greatest value to its members individually, and to the motor car industry. He made it clear to an attentive audience that standardization must begin at the bottom and work up. Every piece that enters into a car must be made of standardized material from designs by standard formulæ, and so processed that it will have the benefit of standard methods of heat treatment and other devices in finishing.

As a direct result of efforts at standardization, L. R. Smith, of the A. O. Smith Company, presented a large number of examples of side frames, cross bars, and other parts as used regularly in automobile work, giving chemical analysis and physical properties of the materials used, offering suggestions as to the methods to employ in designing, and pointing out how the best results will be obtained at the lowest cost of manufacture without in any way interfering with the original ideas of the designer who wishes to impress the imprint of his originality onto the cars of his design. Mr. Smith's splendid work was conspicuously supported by efforts on the part of the makers of steel tubing, who pointed out in a substantial way how it is possible to save cost, and arrive at a fitting conclusion by a no more difficult process than the mere selection of the sizes of tubing that are regularly made, rather than to create new sizes, which is frequently done in the drawing office in the absence of a table of standards to go by.

The whole situation, as one of the results of this meeting of the Society, will end in the appointing of a committee on standards, the same to be composed of 10 capable members, and to be subdivided sufficiently to bring about rapid conclusions, with the expectation that within a relatively short period of time the materials best to employ in automobile work will be given the mark of approval of the committee, and the standards so made, after being accepted by the Society as a whole, will be available to the makers of automobiles. It is undoubtedly true that the supporters of the industry, while they will find this process less spectacular than some other undertakings, will nevertheless observe that it will prove to be of the greatest benefit, ending in a lower cost of maintenance of the cars, if indeed the first cost may not be favorably affected as well.

Perhaps the most interesting paper from the engineer's point of view was that by Professor Bristol on pyrometers. The discussion of this paper will be given in full at the end of the same when it appears in THE AUTOMOBILE, but to indicate something of the value of the paper a portion of the discussion will be quoted here: "One thing he has not brought out is that in using a pyrometer there must be a great deal of common sense put into the use of it. For example, we have seen some pyrometers so installed that the heat junction, that is, the top of the pyrometer, was up by the brickwork, and the people could not understand when the furnace was red enough to anneal steel it did not show more than 800 or 900 deg. F. or something of that kind, and the reverse; they have put it in the hottest part of the furnace, perhaps over the bridge wall, where the flames pass over it continually, and the thermometer cannot by any possibility give the true temperature of work that is on the hearth of the furnace; so that is the reason we say that a whole lot of common sense must be used, and we think one of these arrangements as indicated is a good one."

Mr. Alden raised another question that proved to be of interest: "Will the Bristol pyrometer show more than one of the two or three critical points?" Mr. Bristol answered: "It will only show the first point." Just how nicely the first point was brought out by the Bristol instrument was a subject for demonstration, and many of the members expressed great satisfaction at what they observed.

Eighteen Perfect Scores in Cleveland Reliability

CLEVELAND, Aug. 1—Eighteen automobiles out of a total of 30 which made the three-day reliability tour under the auspices of the Cleveland News and the Cleveland Automobile Club, finished the run Wednesday night with a perfect score.

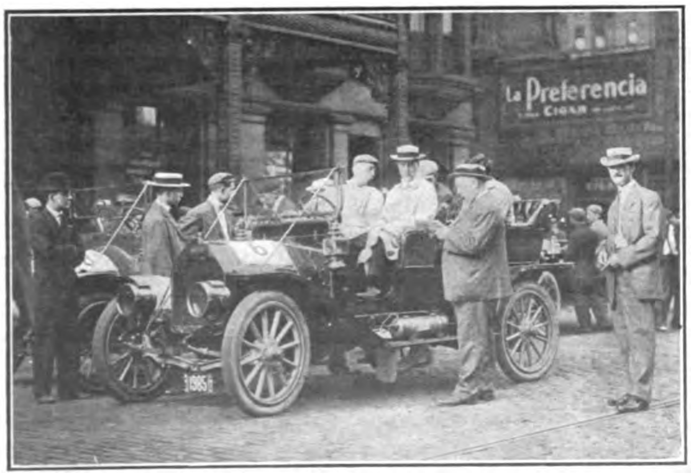
A drenching rain caught the party when it was a few miles out of the city, but had no effect on its enthusiasm. The motorists, traveled-stained and weary, formed into line, and with an escorting party of 50 automobile enthusiasts and a band at their head, paraded to the Hollenden hotel. On Friday night the party again met at the Hollenden to receive the announcement of scores and awards.

Besides the trophy cups awarded by the *News*, a trophy in the 1A class for cars selling under $800 was awarded to the Hupmobile driven by John Rauch. To H. C. Knudsen, who maintained a perfect score with his Overland, was awarded a Goodyear air bottle. John Stambaugh, in a Chalmers "30," was awarded a road map. The penalties incurred by the other contestants were, with only one or two exceptions, due to minor difficulties.

The first day's run ended in Columbus, O. The country was rich in natural beauty, but parched for want of rain, making the dust heavy and the going hard. The big Peerless with its $3,000 Gabriel organ, the Thomas flyer, the Oldsmobile Mudlark, the Chalmers and the 2-ton Garford truck attracted attention along the whole route.

The start on the second day was made at 6:30 in the morning. The route was from Columbus, via Lima, Findlay, Bowling Green to Toledo. The roads were good and there were few hills. Tire trouble was the severest affliction of the day's run. A number of cars were delayed on account of such trouble for much of which the excessive heat could be blamed. Residents along the route tossed apples and other fruits to the motorists as they hastened by.

A heavy thunderstorm during the night at Toledo cooled the air, laid the dust and made the last day's run the most comfortable of the three. As the route led nearer home the size of the welcoming parties in the various towns became larger and larger. At Norwalk where luncheon was had the mayor and other city officials were on hand to greet the party. The street in front of the hotel was blocked for nearly an hour while the crowd eagerly examined the machines. Between Norwalk and Elyria the cars were given their final test for sturdiness. The rain of the night before had filled the holes and ruts with mud and water which made it impossible to gauge the road. The big Studebaker "40," the pathfinder, blew a tire and the confetti was transferred to the following car, a White gasoline car driven by Willie Stutsen, A. A. A. representative.



The E-M-F was among the clean-score cars

The contestants pulled into Cleveland about 6 o'clock. The summary:

No.	Car	Driver	Score
1	Oldsmobile	J. C. Winters	1000
3	Studebaker "40"	Ira Fouche	1000
4	Palmer-Singer	Hugh Miller	1000
6	E. M. F.	Frank Grace	1000
7	Henry "35"	J. B. Sperry	1000
8	Regal	J. C. Hipp	1000
10	Gabriel	A. L. Soper	1000
11	Firestone-Columbus	H. McIntosh	1000
17	Cutting "40"	J. C. Koepke	1000
18	Maxwell	Frank Santry	1000
20	Columbia	C. G. Bleasdale	1000
22	Gaeth	O. Lindner	1000
25	Owen	F. Munroe	1000
27	Garford Truck	Ralph Kinney	1000
33	Oakland "24"	Fred Krum	1000
35	Overland	H. C. Knudsen	1000
36	Chalmers "30"	J. Stambaugh II	1000
39	Hudson	William McCalla	1000
34	Stoddard-Dayton	H. S. Moore	997
16	Hupmobile	John Rauch	990
12	Atlas	Harry Kortz	992
31	Hines Car	F. J. Moore	983
15	Pierce Racine	C. N. White	978
24	Krit	H. Gabriel	976
32	Norwalk "35"	H. B. Olds	967
30	Packard	F. J. Lentz	939
19	Brush	D. E. McCoy	930
28	De Tamble	W. W. Orndorfer	841
9	Hines Car	O. Alexander	805
26	National	D. E. Foote	

Owen, No. 25, also finished without a demerit

Franklin Wins "Little" Glidden Trophy

MINNEAPOLIS, MINN., July 30—Scores of the second annual tour of the Minnesota State Automobile Association were announced late to-day by Dr. C. E. Dutton, the referee. The high score was made by the Franklin, a St. Paul car, which carries with it the *Dispatch* trophy for the Automobile Club of St. Paul. The winner belongs to W. H. Kent.

The Werner prize was also taken by the Franklin. The Gregg trophy for small cars goes to either the Ford or the Reo. according to the maximum price set for the division line of small cars. The two winning drivers get gold medals, and Renville county is awarded the Louis W. Hill good roads prize. Summary:

No.	Name	Driver	Score
1	Pierce	Succow. Phillips	952
3	Hup	E. B. Stimson	896
4	Roe	G. A. Lewis	989
5	Staver-Chicago	Troy Duis	450
6	Halladay	O. A. Palmund	957
7	Cadillac	Rud Stensvad	957½
8	Auburn	W. J. Ranger	851
9	Regal	Arthur La Roche	704
10	Cole "30"	F. J. Seifert	884
11	Cole "30"	W. A. Alden	947
12	Ford	A. A. Hanson	979
13	Franklin	A. H. Clark	997
14	Hudson	O. E. Martin	936
15	Halladay	C. W. Shanno	899
16	Glide	B. E. Sylvester	268
17	Chalmers	J. S. Gilbert	943
18	Carter Car	R. H. Ivey	897

Atlanta's Local Speedway Meet a Big Success

ATLANTA, July 30—Despite postponement of a week, the meeting held to-day on the Speedway proved a success from every point of view. The program consisted of eleven races, six of which were according to piston displacement classes; three were free-for-all; one a pursuit race and the other a match.

The Flanders, Firestone-Columbus, National and Pope-Hartford entries won a majority of the events. The Fiat and Simplex divided the two free-for-all dash races, but the Firestone-Columbus won the open handicap.

The prettiest finish of the day was in the eighth race at 8 miles, when the E-M-F. won from the Firestone-Columbus by inches after being defeated by the same car in a preceding race.

The Fiat 60 belonging to Asa Candler, Jr., had a narrow escape from destruction when the steering arm broke and the front wheel buckled while making about 70 miles an hour in the second free-for-all. The summary:

Two mile time trials—

Car	H.P.	Entrant	Driver	Time
Fiat	60	Asa Candler, Jr.	W. J. Stoddard	1:34 3-5
Simplex	50	E. H. Inman	R. Church	1:37 3-5
Buick	30	W. E. Wimpy	E. W. Smith	1:55 4-5
Cadillac	30	A. Lemon	A. Lemon	2:07 3-5

Columbia, No. 20, one of the Cleveland "immaculates"

For 160 cubic inches and under, six miles—

Flanders	20	G. W. Hanson	H. A. Witt	6:38 3-5
Benz	18	G. W. Hanson	H. Cohen	
Hupmobile	20	E. D. Crane	H. H. Hall	

Match race, ten miles—

National	40	W. J. Stoddard	W. J. Stoddard	8:39
Renault	35	Asa Candler, Jr.	J. Woodside	

For 231 to 300 cubic inches displacement, twelve miles—

Pope-Hartford	25	F. Steinhauer	R. Church	11:53 4-5
Maxwell	30	Max.-Bris. S. Co.	J. Roach	
Maxwell	30	Max.-Bris. S. Co.	M. LaHatte	

160 cubic inches and under, ten miles—

Flanders	20	G. W. Hanson	H. A. Witt	9:20
Hupmobile	20	E. D. Crane	H. H. Hall	
Fiat	12	J. M. Nye	J. Taylor	

161 to 230 cubic inches, ten miles—

Firestone	30	E. D. Crane	McKinstry	8:35
E-M-F	30	R. W. Hanson	Cohen	
Maxwell	22	Max-Bris S. Co.	Rambo	

Free-for-all, ten miles—

Fiat	60	Asa Candler, Jr.	W. J. Stoddard	8:03 3-5
Simplex	50	E. H Inman	R. Church	
Renault	35	Asa Candler, Jr.	J. Woodside	

Australian pursuit race—

Renault won from Buick and S. P. O., Time 11:11.

161-230 class, eight miles—

E-M-F	30	R. W. Hanson	Cohen	7:34 3-5
Firestone-Columbus	30	E. D. Crane	McKinstry	
Oakland	30	J. L. Wright	Moss	

Free-for-all, ten miles—

Simplex	50	E. H. Inman	R. Church	8:16 3-5
Renault	35	Asa Candler, Jr.	J. Woodside	
S. P. O.	38	W. Candler	Toole	

231-300 cubic inches class, twelve miles—

Pope-Hartford	25	F. Steinhauer	R. Church	12:33 1-5
Parry	32	R. C. Howard	B. T. Phillips	

301-450 cubic inches class, twelve miles—

Car	H.P.	Entrant	Driver	Time
S. P. O.	38	W. Candler	Toole	12:38 2-5

Free-for-all, ten miles, handicap—

Firestone-Columbus	30	E. D. Crane	McKinstry	11.
Maxwell	22	Max.-Bris. S. Co.	Rambo	
Renault	35	Asa Candler, Jr.	Woodside	

Bad Roads Cost Farmers $225,000,000 in 1909

NIAGARA FALLS, July 30—The Third Annual Good Roads Congress adjourned to-day after three days of deliberation which were filled with consideration of projects that are of the utmost importance to the citizens of the United States and other American countries. The convention was not as well attended as had been hoped, but nevertheless it drew out a representative gathering of men high in business, finance and professional life. One of the most striking of the addresses was that of B. F. Yoakum, chairman of the Board of Directors of the 'Frisco System.

The gist of his speech was contained in the following remarkable statement:

> "On the basis of the government's estimate of the present excess cost of fifteen cents a ton for hauling in this country as compared with European countries, improved roads would have meant to the farmers on last year's crop an additional $225,000,000, thus increasing their $8,750,000,000 crop to $10,000,000,000.
>
> "Every detailed analysis of the government's business methods proves them to be wasteful. One of the ablest United States Senators recently announced that the government could be run for $300,000,000 annually less than it is now costing.
>
> "I can say as emphatically that $300,000,000 annually will give to this country 100,000 miles of improved public highways a year.
>
> "If you take up your work of better roads, to be paid for through a reduction of governmental waste, your work will be effective and for the general good of all."

The second day of the conference was devoted in large part to the needs of the South and Southwest. J. Hampton Rich and John Crafts of Alabama were the chief speakers.

The final day was given up in part to the consideration of a plan to build a great boulevard from New York to Niagara Falls. The other important work of the session was the action taken to secure federal co-operation in the matter of building roads.

The chief speakers of the convention aside from those named above were: Arthur C. Jackson, president of the association; Mayor Douglass of Buffalo; Congressman William F. Sulzer; Charles B. Matthews; the Mayors of St. Catherine and Guelph, J. A. Pennypacker, Jr., George A. Colley; former U. S. Senator Dodge of Ohio; A. G. Spalding and James L. Cowles.

The next important good roads meeting will be held at Oklahoma City, October 4 to 6.

Palmer--Singer, No. 4, was also unpenalized in Cleveland run

News Happenings of the Week in Detroit

DETROIT, MICH., July 31—The awarding of the Glidden trophy is not the only thing to cause the Chalmers Motor Company satisfaction, however. At a meeting of the company, last Tuesday, a cash dividend of 30 per cent. on the $300,000 capital stock of that concern, and a 900 per cent. stock declaration was made as a result of last year's operations. The stock dividend is represented by an increase in value of shares from $10 to $100, and the boosting of the capitalization from $300,000 to $3,000,000.

None of this increase is to go on the market, it being distributed pro rata among the present stockholders. Two years ago the Chalmers plant was comparatively insignificant. Since then it has been developed into an institution of the first magnitude, more than $1,500,000 have been invested in new buildings and machinery which turns out practically the entire car.

Considerable discussion has been indulged in locally because after purchasing a large tract of land in Detroit, the General Motors Company failed to begin operations on the immense plant it was promised would be located here. On the authority of John H. Johnson, president of the Peninsular Savings Bank, and closely identified with General Motors affairs, active building operations will begin as soon as track arrangements and some other details have been completed. Mr. Johnson also stamps as unfounded the rumor persistently circulated in local automobile circles that the Buick plant would be removed from Flint to this city.

The Aetna Investment Company, organized some time ago for the purpose of building a five-passenger touring car, has progressed to a point where it feels justified in increasing its capital stock from $5,000 to $20,000, this action having just been taken.

To date the State treasury has been enriched more than $51,000 by the sale of automobile and motorcycle licenses, something over 16,000 of the former and 867 of the latter having been issued. In addition orders have been placed for 23,000 tags to be delivered before Jan. 1 next.

The good roads sentiment worked up in Detroit and which promised to bear immediate fruit, must be nursed for a time yet because of legal obstacles in the way of securing an immediate submission of the question of a $2,000,000 bond issue for the purpose. The Board of Commerce had planned on having the question of bonding decided at once, but the law limits the county supervisors to two special meetings a year. These have been held, and the bond proposition will have to wait until the regular election in November, at which time it will be submitted to the voters.

Carload of Franklin branch managers and salesmen gathered at the Syracuse factory for the annual conference

The Grabowsky Power Wagon Company is preparing to move into the immense reinforced concrete plant it built at Mt. Elliott avenue and the Michigan Central Belt Line Railroad.

The Warren Motor Car Company has the first unit in its new plant well under construction; the Regal Motor Car Company will soon be able to occupy the great factory it is building on Piquette and Harper avenues, and the Metzger Motor Company is ready to break ground for its truck plant in the northern part of the city.

From Alpena comes the announcement that "Alpena Flyers," being manufactured there by the Alpena Motor Car Company, will make their appearance some time during August.

The Aero Club of Michigan has just had built for its use Michigan No. 1, a balloon of 45,000 cubic feet capacity.

The Cadillac Company plans to put out 12,000 cars for 1911. It has received from agents advance payments on 8,000 of these and the remaining 4,000 are also spoken for, although no advance payments have been made on them. Earlier in the year the Cadillac had some very pretentious building operations under contemplation. While all of the additions and new structures projected will be erected ultimately, only one of them will be built this year. This, with the old street-car barns recently acquired, will give the company all the additional facilities required for the immediate future, and will be in conformity with the conservative policy that has been followed by the Cadillac Company from the outset.

Frank Briscoe, chairman of the executive committee in charge of the Detroit division of the United States Motor Company, and president of the Brush Runabout Company, pointed to the extensive building operations the United States Motor Company now has under way in Detroit, as showing its confidence in the future of the industry as far as its own operations are concerned.

Overland "Wind Wagon," a cross between automobile and aeroplane, which covered five miles in 5:20

"The Brush Runabout Company is just completing its 1910 output," he said. "We are preparing to turn out at least 15,000 cars next season, and by Jan. 1 we may decide to increase the number to 20,000. The past season's business brought a satisfactory profit, which, we expect, will be trebled next season.

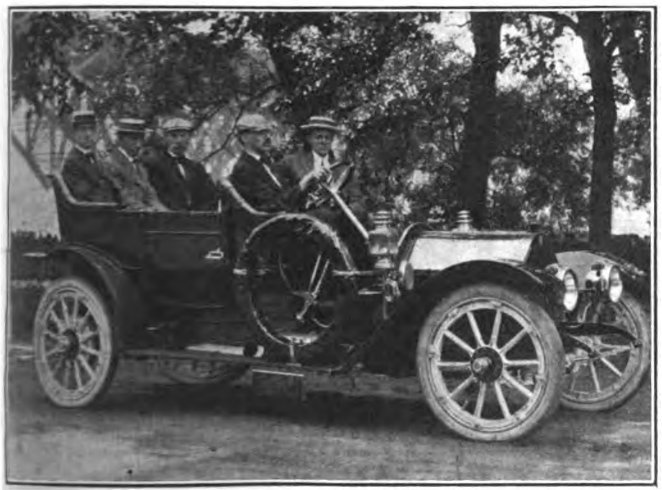
"The Briscoe Manufacturing Company has cut out its night work, but is running practically as strong a day shift as ever. Its sales of parts, exclusive of the Brush Runabout business, have amounted to $1,300,000 for the past year, and we expect they will be about $2,000,000 for the coming year. We have plenty of orders in hand and have had hold-ups but no cancellations.

"None of the constituent companies of the United States Motor

Company has had difficulty in disposing of its product, and each anticipates an increased production of cars the coming season.

"As to the general situation, I doubt if there is a concern, provided it is properly organized and managed, that is not as strong financially as any company of the same capitalization in any other line. There is, however, a general feeling of conservatism through the trade, and some of the wild plans for increase have been abandoned or modified."

Work on the Detroit factory of the Alden Sampson Company is progressing rapidly. The foundations are laid, the footings are in, and the entire building, measuring 150 x 1050 feet, will be completed by Sept. 15. The contract for the administration building was let during the past week. This will be 55 x 75 feet, two stories high, with outer walls of white pressed brick. General Manager Morris Grabowsky plans to start moving [redacted] main building as soon as the first 400 feet are com- hich will be about Aug. 10.



[redacted] Bergdoll "30" turned out of the factory—Vice-president nson at wheel, Technical Manager Willie Haupt beside him

[redacted] Motor Machinery Company has purchased a fac- 196 x 200 feet, on Franklin street, between Joseph venue and Chene street, and will build at once. The for the land was $14,000.

[redacted] nufacturers of the Houpt-Rockwell high-power cars ing to invade the Michigan field, and have engaged F. Bates & Co. as their Michigan distributors. It is to establish a garage and salesroom in Detroit, and a will be carried.

The Steely Auto Engine Company filed articles of incorporation with the Secretary of State last week. The company is capitalized at $150,000, and the principal stockholders are Michael G. Delowey and Charles M. Steely.

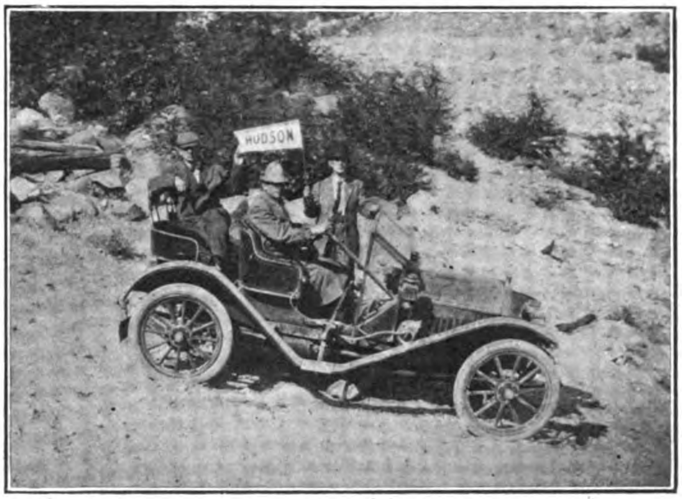
Owing to largely increased business in this territory the Ohio Seamless Tube Company, of Shelby, O., manufacturers of cold-drawn seamless tubing, have opened a selling office in this city at 913 Ford Building, with Lloyd Brown in charge.

General Manager Fred W. Haines and Sales Manager George Wilcox, of the Regal Motor Car Company, have returned from a tour of the Regal branches in the West. They report that they found conditions in that section most satisfactory.

"Bobbie" Davis, manager for the Maxwell-Briscoe-McLeod Company, is taking a well-earned rest. Between selling cars and looking after the details of the recent auto parade, Mr. Davis was just about "all in" at the close of the Elks' reunion. He has gone to Buffalo with his wife and daughter.

J. M. Deuenas, a Chalmers dealer in Havana, is in the city arranging for his allotment of 1911 cars. Automobiles are growing constantly in favor in Cuba, he says. He reports an excellent trade in Chalmers cars for the past season.

"Automobile Day" at the Michigan State Fair, Sept. 24, will be enlivened by some interesting speed contests.



Hudson car which recently made 141-mile non-stop run to Mount Tacoma

That the Elks' reunion is bringing results as far as local car dealers are concerned is already apparent. Dr. C. S. Kramer, past exalted ruler of the Pueblo, Col., lodge of Elks, who was a delegate to the convention, is driving home in a Cole "30," purchased from the local agency.

Stoddard-Dayton Wins Salt Lake Free-for-All

SALT LAKE CITY, UTAH, Aug. 1—The *Evening Telegram's* third annual hill-climbing contest held Saturday afternoon was by far the most successful event of its kind ever held in this section of the country. There were forty-two entries. The course was up what is known as Brigham street and was one mile in length, with a good grade all the way and with a sharp turn at the last quarter. There was one dispute. Samuel Newhouse, who gave the $1,000 trophy in the free-for-all, protested against the award of the cup to the Sharman Automobile Co., which entered both the Apperson and the Stoddard-Dayton. Newhouse contends that Driver Frank Seifert held back the Apperson in order that the Stoddard might win. A Thomas made an exhibition run up the hill in :56 2-5. The summary:

$800 class—Won by Hupmobile in 2:26 4-5.

$1,200 class—Won by Ford; time, 1:48 2-5. Buick 10, second; time, 1:51.

$1,800 class—Won by Stoddard-Dayton; time, 1:45 2-5. E-M-F second; Overland, third; Buick, fourth; Cadillac, fifth.

$3,000 class—Won by Stoddard-Dayton; time, 1:11 2-5. Buick, second; Winton, third; Premier, fourth; Buick, fifth.

$4,000 class—Won by Apperson; time, 1:05. Stoddard-Dayton, second; Thomas 40, third; Palmer-Singer, fourth; Buick, fifth; Premier, sixth.

$2,000 class—Buick and Velie tied for first; time, 1:25. Stoddard-Dayton, third; Buick, fourth; Overland, fifth.

Free-for-all—Won by Stoddard-Dayton; time, 1:08 3-5. Palmer-Singer, second; time, 1:11 2-5. Apperson, third; time, 1:12 2-5. Premier, fourth; Buick, fifth; Thomas Flyer, sixth; Packard, seventh; Velie, eighth; American, ninth; Studebaker, tenth.

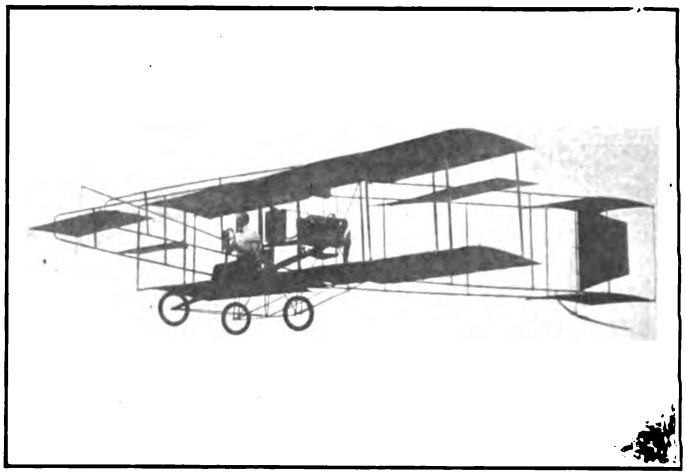
Aeroplane Propulsion Copied on a Land Car

The Overland "Wind Wagon," with Carl Baumhofer and Cleve Jeffries as pilots, which is now touring the Southwest giving a series of exhibitions, is an automobile driven entirely by an eight-foot wooden propeller in the rear. The machine created quite a sensation at the recent Indianapolis Speedway meet, where it negotiated five miles in five minutes and 20 seconds.

The Bergdoll "30" Makes Its Initial Bow

The new Bergdoll "30," product of the Louis J. Bergdoll Motor Company of Philadelphia, is about to make its advent. In fact, a few of the cars have been finished and many are in the final stages of manufacture. The factory was instituted less than a year ago at Thirty-first and Dauphin streets, and more recently the plant has been augmented by the acquisition of a building at Sixteenth and Callowhill streets, thus giving a floor space of 200,000 square feet. The officers of the company are: Louis J. Bergdoll, president; E. C. Johnson, vice-president; P. S. Malickson, secretary, and Charles A. Bergdoll, treasurer.

"Bleacherites" watching the races at Hempstead Plains



Captain Baldwin trying out his bi-plane

Aviation News of the Week

AVIATION from the viewpoint of the Summer visitor is one of the chief attractions of many of the resorts located near the metropolis. In a dozen different places, the air machines are busy every favorable day and the flights attract an immense amount of attention from the public.

Garden City, Narragansett Pier, Asbury Park, Atlantic City and a number of other places are the scenes of daily flights by professionals or amateurs. The newest thing in aircraft shown at these resorts is the French dirigible "Zodiac IV."

This ship, which is the smallest of the French dirigibles built so far, is owned by Stuart Davis of Scarborough, who has been studying aviation in France for the past six years. The vessel will be used as a pleasure craft and its official trial trip is scheduled for August 10. The gas bag is 109 feet long and the ship will carry four passengers.

Charles K. Hamilton, one of the earliest entrants for the $30,000 prize for flight between St. Louis and New York, has outlined his plans for the trial. He says he will start from St. Louis and prefers to make his official attempt for the big prize during the Indian Summer. A special bi-plane is in course of construction for Mr. Hamilton, which will include the most thoroughly tested features of that type of aircraft and will be equipped with wires having a tensile strength of 2300 pounds.

In speaking of the trip, Hamilton said: "I shall try to accomplish the flight as quickly as possible. There is no reason why an aeroplane should not fly ten hours a day and there is really nothing to prevent night flights. While I shall have to have gasoline and oil stations at a number of places. I shall carry an extra propeller and tools on board so as to be able to make repairs if forced to alight in out-of-the-way places, as I was in my return trip from Philadelphia."

The military significance of the recent aeroplane tests in the United States have found a resounding echo in foreign countries. While no public tests have been made, as far as is known, the results of the feat of Curtiss in America have caused an immense amount of conjecture and speculation. A leading official of the French Ministry of Marine in discussing the situation said: "Of course all that has been done in America could be duplicated here and the actual accomplishment in the United States is not in the least surprising to us. We have long accepted that fact as self-evident. The real question involved is as to whether the aeroplane could drop the bombs with the same accuracy under war conditions.

"Doubtless, should war break out to-morrow, the aeroplane would find use in the army and navy in an experimental way. This use would be vastly expanded by the development of reliability under adverse conditions."

Twenty French army officers have obtained licenses to pilot aeroplanes.

In speaking of the American war tests, Santos-Dumont said: "Any one who has flown knows it is very easy to drop an object from an aeroplane so as to hit a selected spot. Absolute accuracy depends only on practice."

Santos-Dumont hopes that the advent of the aeroplane in the field of war will make that practice so horrible that mankind will turn from bloody conflict to universal peace.

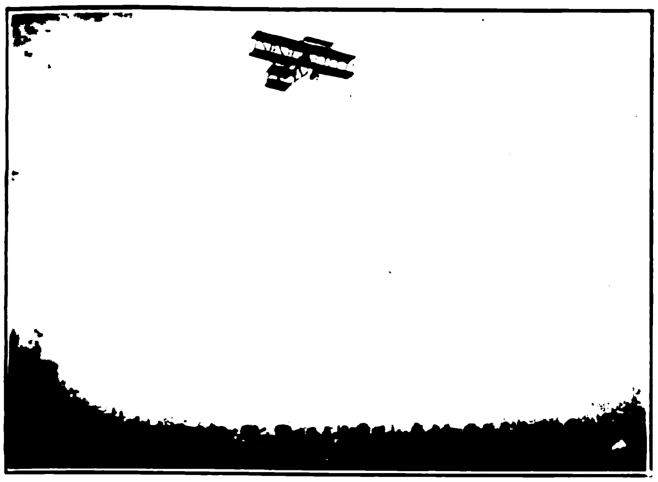
Count Jacques De Lesseps has returned to France. Before sailing he expressed the wish that he might be able to enter the international aviation meet on Long Island in October.

The Harvard Aeronautical Society has purchased a tri-plane from a British manufacturer and the machine will be used in the series of military tests on Soldiers' Field in September. The plans for these tests include a trial of accuracy in dropping bombs within the outline of a battleship. A prize of $5,000 has been offered.

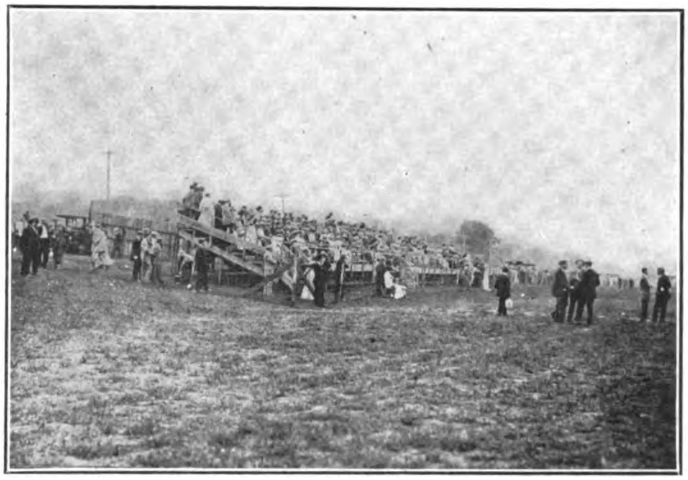
Mrs. Russell Sage, widow of the former Wall street multi-millionaire, witnessed the flights at Garden City, L. I., last week and after seeing a number of exhibitions exclaimed that she had caught the fever and stood ready to back any woman inventor of aircraft to demonstrate the feasibility of her ideas.

Alan R. Hawley, former vice-president of the Aero Club of America, has suggested a new use of the aeroplane. Mr. Hawley says that there is nothing to prevent aircraft from lending ma-

J. A. Drexel, of Philadelphia, ready for a start at Bournemouth



Harmon's bi-plane doing 50 miles an hour



The grand stand at Hempstead Plains is always well filled

terial aid to stranded ships by carrying lines to them from shore. He and several others interested in aeronautics are now arranging for the construction of a number of aero landings along the New England coast.

Clifford B. Harmon, the amateur flyer, has declined to make any further flights at Garden City if admission fees are charged. Big crowds have been attending the trials and Mr. Harmon's action was taken after he said he was certain that the gate receipts had been sufficient to defray the expense of the management in fitting the field for aviation.

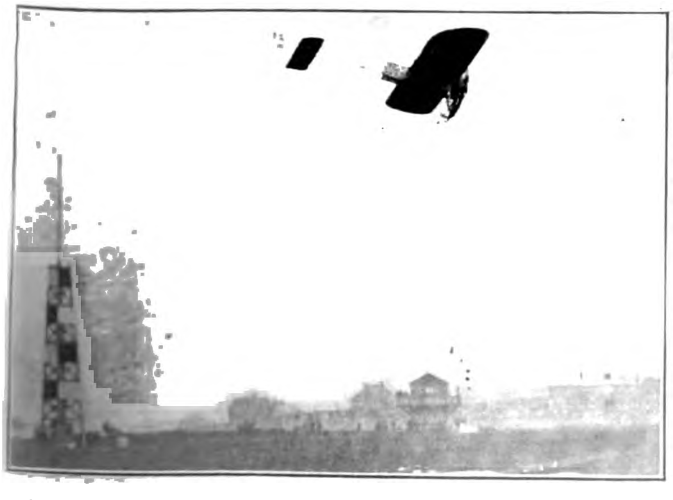
The attempt at crossing the Atlantic ocean in a dirigible is taking something like definite form. The airship, "Amerika" is due to arrive Wednesday on the steamer Oceanic from Paris and will be set up at Atlantic City at once. Melvin Vaniman, aviator and mechanical engineer, is already here and says that on or about August 20 the start will be made. He says he expects to land in England in four or five days. Walter Wellman and five others are slated to man the "Amerika" on the voyage.

In the recent aero tournament at Bournemouth, England, Morane, pilot of a Blériot racer, won the first prize of $4,000 by a flight encircling the Needles. Armstrong Drexel, of Philadelphia, was second, also in a Blériot, and was awarded $2,000 and Grahame White, third, in a Farman bi-plane, receiving $500.

This competition, while in no sense a racing spectacle, proved exciting enough to receive much enthusiastic attention. But the event that was on the program as the star number was never called.

It was a proposed race between motor boat and aeroplane and the leading entrants in both divisions suffered mishaps before the event, that caused the officials of the meeting to call it off.

The arrangements for the race were made as the result of a challenge from the Motor Yacht Club to the Royal Aero Club for a suitable trophy. On the part of the yacht club, the Duke of Westminster entered a specially constructed hydroplane, equipped with a 400-horsepower engine and the Royal Aero Club selected the Hon. Charles Stuart Rolls to represent it.



Morane, the Blériot pilot, making a landing at Bournemouth

About a week before the date set for the race, the Duke of Westminster, while taking a practice spin, put his helm hard over while the hydroplane is said to have been making nearly fifty miles an hour and the boat capsized. The duke escaped drowning by virtue of prompt rescue measures of the life-saving crew stationed nearby.

A few days later, Mr. Rolls suffered his fatal mishap in front of the Bournemouth grandstand and the contest was scratched.

The conditions under which the circle of the Needles was made were picturesque.

From the flying ground competitors had to ascend and make over water toward the Needles, a line of tall sharp rocks standing on the Eastern extremity of the Isle of Wight. Circling the lighthouse there, they had to return and alight before the grandstand. The distance over the water was just over nine miles in a straight line, making the trip just over 18 miles long, and with a turn round the aerodrome and the descent, 21 miles.

Morane rose in the air one evening about six o'clock, and, having encircled the aerodrome, shot out over the sea and within six minutes was lost to sight at an altitude of over 1,000 feet. Armstrong Drexel, also on a Bleriot machine but with a 25-horsepower Anzani instead of the 50-horsepower Gnome engine which Morane employed, followed. He also flew high and vanished into the haze over the sea. Across the belt of water stretched a line of steam yachts and racing motor boats, ready to render assistance if necessary.

Just as Drexel disappeared from sight Morane came into view high in the air. Almost as soon as his mono-plane took distinct form, he shut off the engine and came to earth with a glide from an altitude of nearly 2,000 feet. He had flown very fast, and had taken only just over 25 minutes, his average speed working out at 50 miles an hour. Though Drexel had passed him as he was returning Morane had seen nothing of him. Within a quarter of an hour the American reappeared and landed in front of the stands. His speed had been only 35 1-2 miles an hour, the time he occupied being 35 1-2 minutes. Grahame White made the circle in 46 minutes.

Twenty-five Enter Munsey Historic Tour

WASHINGTON, D. C., July 31—Five more cars were entered this week in the Munsey Historic Tour, bringing the entry list up to twenty-five. The additions were two Maxwells, entered by the United States Motor Company, a Staver-Chicago, by the Staver Carriage Company, a Stoddard-Dayton, by Leo H. Shaab, the Baltimore agent, and a Crawford by Walter Scott, of Baltimore. The entries will close at midnight, August 5, at which time it is expected more than 30 cars will be enrolled.

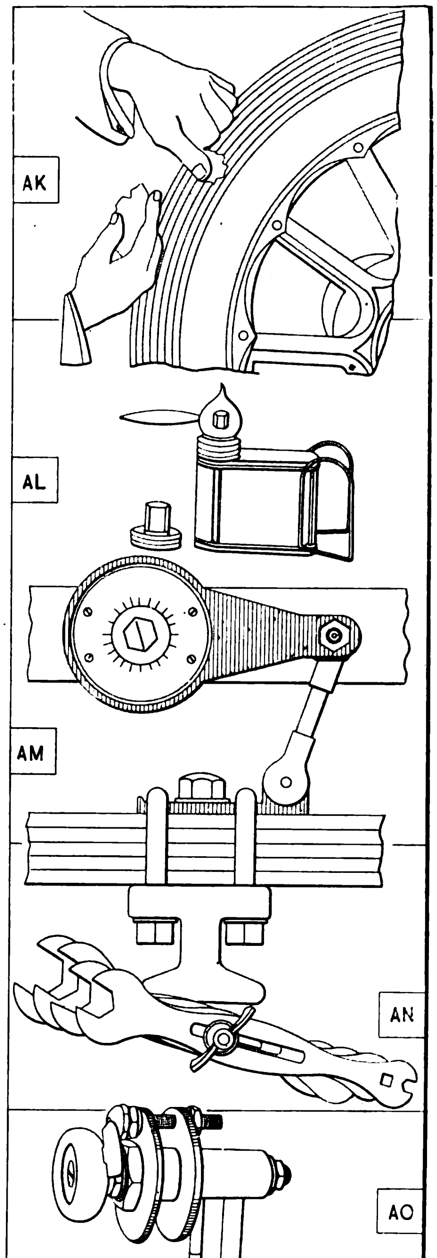
Seen in the Show Window

ON the principle that "a stitch in time saves nine," every autoist should see to it that his repair kit contains a can of Knead-it (AK), which is made by the M. & M. Manufacturing Company of Akron, O. The main merit claimed for this article is that by applying a little to a slight cut or sand blister as soon as it is discovered, the autoist prevents its growth to the point where a blow-out results. The material in kneaded between the fingers and stuffed into the cut, where it sets quickly, and seals so securely and permanently that it becomes really a part of the tire.

THE terrors of a leaky pipe or joint on the road would seem to have been minimized by the recent appearance on the market of a handy little soldering outfit, the Tinol Torch (AL), which is handled by Hess & Son, 1215 Filbert Street, Philadelphia. This is an extremely neat and compact self-acting blow-torch, burning methylated spirit and giving a hot, well-defined flame about four inches in length and sufficient for all soft soldering purposes. The solder itself, a finely granulated alloy of tin and lead, mixed with an oily flux, is in paste form. It is spread thinly on the surface of the metal to be soldered and then heated. The compound melts, the flux evaporates and the solder hardens and adheres closely to the metal.

THE principal point of merit in the Martin Shock Absorber (AM), manufactured by the company of the same name at 926 Central Avenue, Los Angeles, Cal., is that it acts only on the rebound of the springs. The spider is bolted to the car frame and carries with it all parts of the absorber except the ring and the arm which is integral therewith. This arm is linked to the axle by a connecting rod provided with ball-and-socket joint. The downward movement of the car body revolves the ring to the right. Revolution of the ring in the opposite direction through the rising of the car body causes the toggle bars to straighten, thus expanding the brake shoes against the ring. The absorber is packed in hard oil and needs no additional lubrication.

UTILIZATION of space in the tool kit, under the conditions of body designing which are fast taking shape, is a factor well worth considering. A means to this end is the Ronson Wrench (AN), made by the Ronson Specialty Company, 7-15 Mulberry Street, Newark, N. J. Weighing but half a pound, and but six inches long when closed, and half an inch thick, this handy combination tool—it gives nine wrenches in one—can be carried in a side pocket if need be. Once set, the turning of an individual wrench is impossible. It can be also taken apart, and each wrench used separately.



(AK)—"Knead-it" Tire Seal
(AL)—Tinol Soldering Torch
(AM)—Martin Shock Absorber
(AN)—Ronson Combination Wrench
(AO)—Presto Auto Lighter
(AP)—Skinner Automatic Pump

PHYSICIANS and car owners whose business necessitates much night driving will appreciate the advantages of such a handy little dashboard accessory as the Presto Auto Lighter (AO), marketed by the Motor Car Sales Company, Motor Mart, Boston, Mass. Without leaving his seat the driver, by one turn of a switch, creates the spark and at the same time turns on the acetylene gas. In the matter of economy the lighter is especially noteworthy. The average driver at night allows his headlights to remain burning, no matter how long the stop, rather than bother about turning off the gas and relighting his lamps when ready to go on his way. With his car equipped with this lighter he will turn off his lights at each stop, no matter how short, the saving effected being considerable in the aggregate.

LET the engine do the work—that is the slogan of the ease-loving autoist. And in the matter of inflating tires this is an easy proposition with the aid of the Skinner Automatic Tire Pump (AP), made by Skinner & Skinner Company, 1716 Michigan Avenue, Chicago, Ill. All that it is necessary to do is to remove one spark plug, screw the connection into the spark plug hole, run the engine two or three minutes on low throttle, and the tire is hard and round. The pump can be attached to any size of motor, and it is not necessary to race the engine to obtain a high pressure.

THE Racine Auto Tire Company, of Racine, are putting out what they call the Racine "Horseshoe" Tires, and claim to be the only manufacturers making a leather tire with a perfectly intact all-leather exterior. These tires are composed of four thicknesses of chrome-tanned leather vulcanized together and to a specially constructed carcass having a rubber bead of standard size. The manufacturers maintain that tests have proven that it requires about 1,000 pounds pressure to puncture one thickness of chrome-tanned leather. In the making of these tires four thicknesses of leather are used, each inseparably joined to another and the four layers vulcanized to the inner carcass.

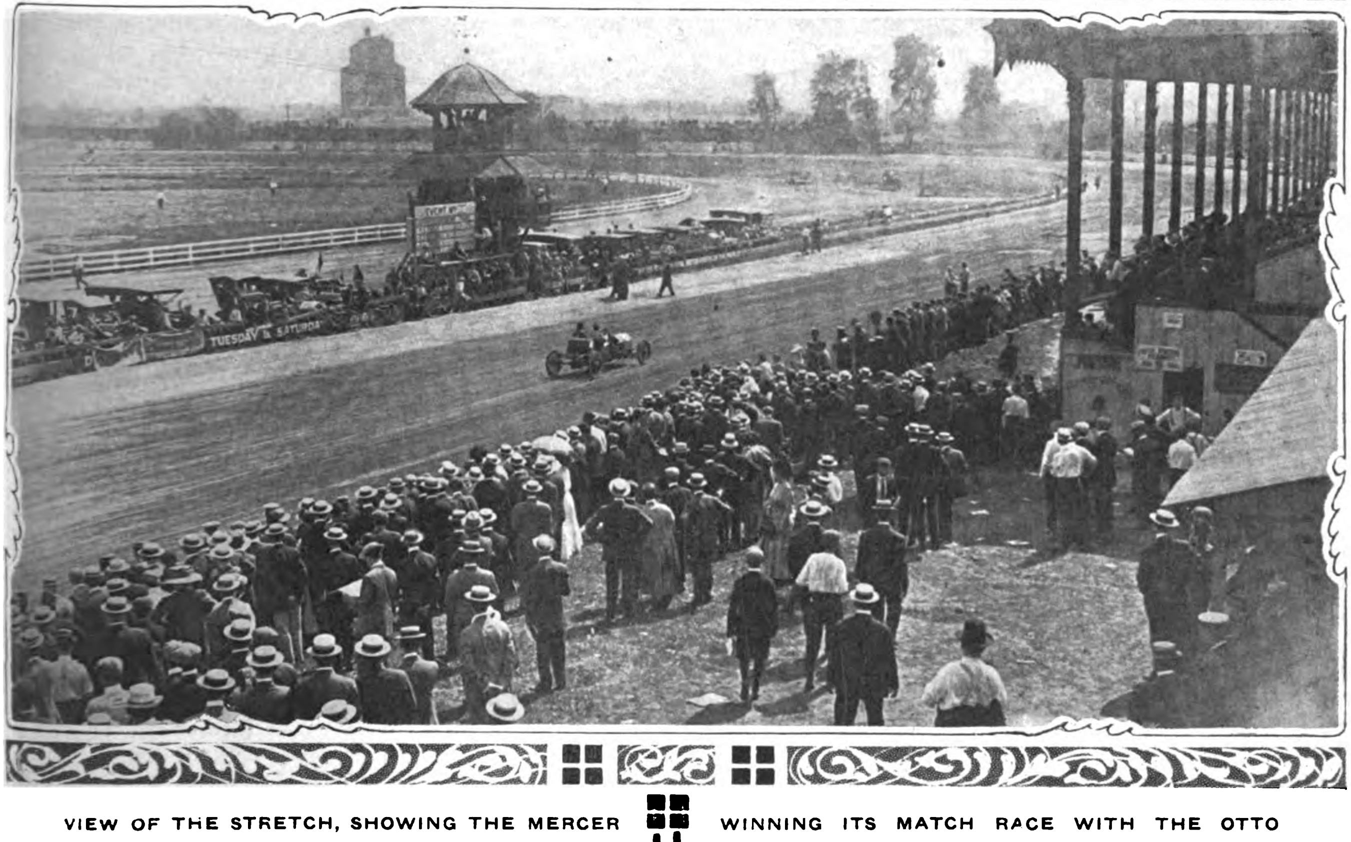
VOL. XXIII NEW YORK—THURSDAY, AUGUST 11, 1910—CHICAGO No. 6

THE AUTOMOBILE

Q. C. M. C. Midsummer Meet

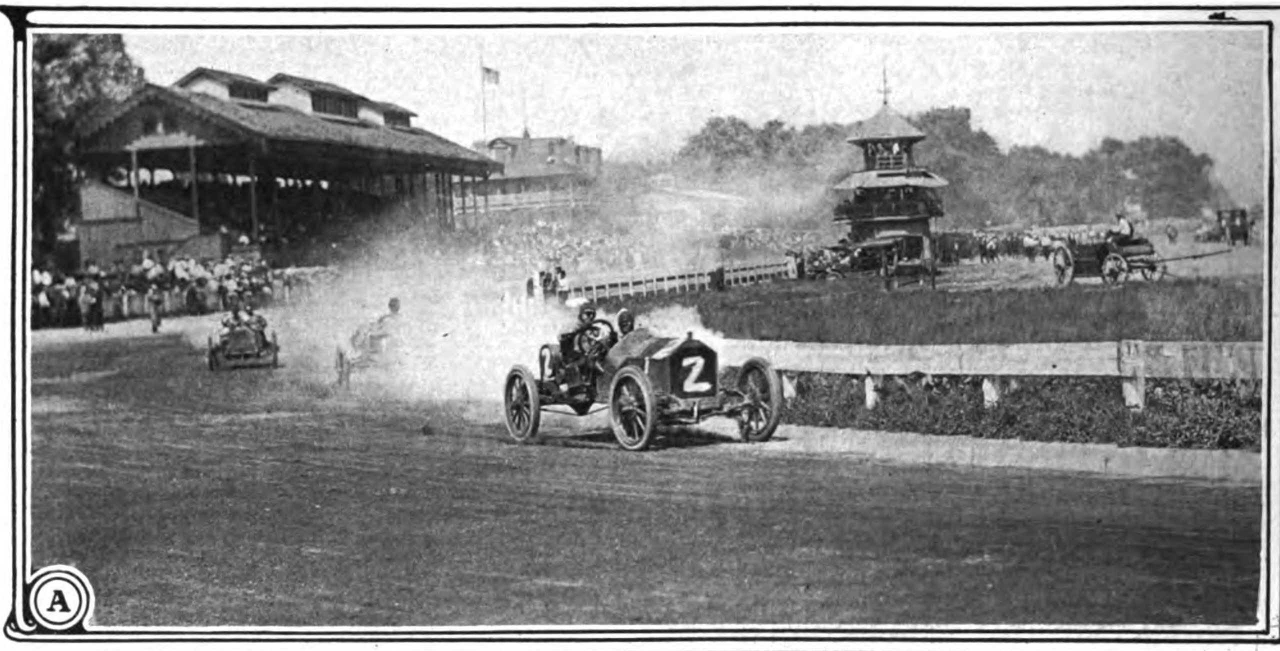
CRACK PHILADELPHIA ORGANIZATION PROMOTES THE MOST SUCCESSFUL AFFAIR IN ITS HISTORY BEFORE A RECORD-BREAKING CROWD.

PHILADELPHIA, Aug. 8—That this city is not yet prepared to abandon automobile track racing was demonstrated on Saturday afternoon, when, at the midsummer meet of the Quaker City Motor Club, the crowd of upwards of 10,000 not only packed the stands, hotel porches and paddock at Point Breeze track, but a contingent of thousands more broke down the fence along the back-stretch and swarmed into the inclosure despite the efforts of a large force of policemen.

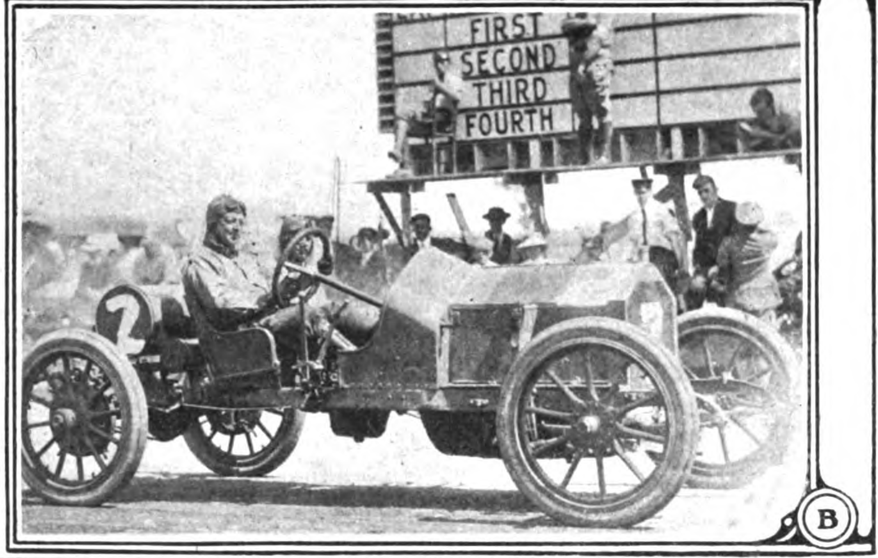


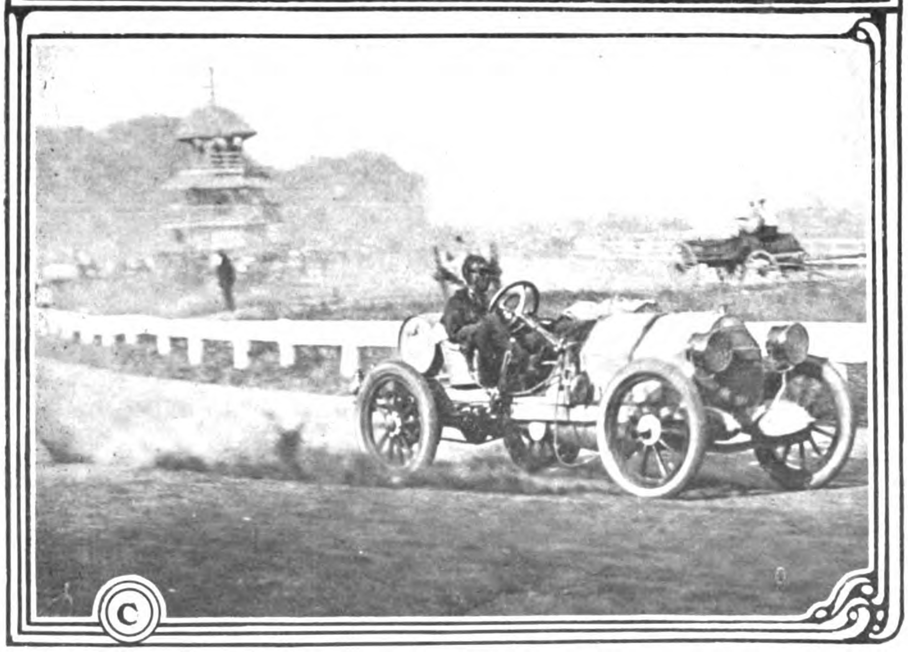
VIEW OF THE STRETCH, SHOWING THE MERCER WINNING ITS MATCH RACE WITH THE OTTO

The six-hour race was the big event of the day. Seven cars started: Knox, B. Oldfield; Kline-Kar, W. D. Morton; Darracq, B. Kerscher; Ford, F. Kulick; Pullman, H. Ringler; Selden, C. Young, and Chalmers "40," C. Howard. Getting off to a good start the drivers settled down for the long grind. Kerscher, in the Darracq, jumped to the front, but was forced to relinquish the lead shortly to the Knox, which forged ahead and at the end of the first hour had twice lapped the Darracq. the runner-up. The Pullman had hard luck throughout the contest, having to leave the track several times, starting with the very first lap, when it threw a rear tire. At the end of the second hour the Knox was seven miles ahead of the Kline-Kar, which had usurped the Darracq's place as contender, engine trouble shortly after causing the latter to withdraw. At the end of the fourth hour the Knox had a lead of 12 miles and it was only a question as to how many miles the car would make. In the fifth hour a very pretty race developed between the Kline-Kar and the Ford for second place. So fiercely was it fought out that at the end of the hour each car had covered 209 miles. Minor troubles developing, however, caused the Ford to lose ground in the last hour. At the end of the race the Knox had completed 261 miles, Kline-Kar, second, 245; Ford, third, 226; the Chalmers "40", fourth, 218, and the Selden, fifth, 167.



A—Ringler's Pullman leading in the 450-and-under event





B—Pullman-Ringler combination—two-time winner

C—The Kline-Kar which finished second in six-hour race

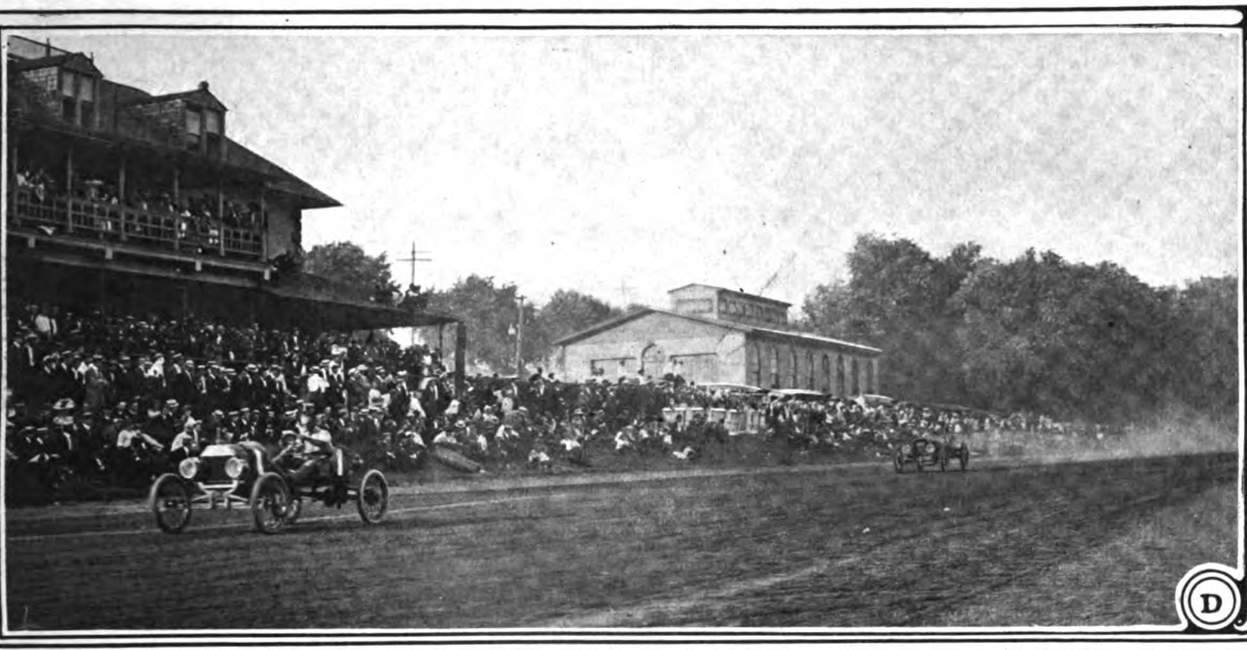
The real feature of the meet was the performance of Harvey Ringler, an amateur driving a Pullman. He not only won the 161-300 cubic inch and the 450-and-under event for Class C cars, but his time in the latter was the best for the distance made during the meet—11:30 flat. The Pullman also started in the 750-and-under event, in which it came in third, and in the six-hour race, from which it was withdrawn owing to cylinder trouble.

The time trials were only partially successful, for while the Knox clipped 1 2-5 seconds off the previous best mile track record after two trials, the Darracq's attempt to lower the five-mile figures—5:13—was unsuccessful by a margin of 8 1-5 seconds.

The first race run off was a match race for blood between a Mercer driven by J. Sherwood and G. H. Jones' Otto. The latter had the misfortune to throw a tire on the very first lap and before he could get going again his opponent had opened up a seven-lap lead, finally crossing the tape by that margin in 12:28 2-5.

Everybody picked the Ford-Kulick combination to win the 161-300 cubic inch 10-mile event, but the Pullman, driven by Harvey Ringler, the clever amateur, assumed the lead about the third mile, adding to its advantage with every lap to the finish, flashing under the wire in 11:33 2-5, with the Ford 300 yards behind the Otto, which captured the place.

In the 450-and-under Class C event at ten miles, C. C. Fairman's Kline-Kar being an added starter, the Pullman repeated, this time beating the Ford by a full half mile in the best ten-mile time of the day—11:30. The Kline-Kar and



D—Crowd encroaching on track in six-hour race—Ford leading Pullman

the Otto were lapped by the leaders on the seventh mile and dropped out.

In the 750-and-under race, in which the Pullman, Kline-Kar, Darracq and Knox were the starters, the latter went to the front at the gun and was never headed, winning by the small margin of one-fourth of a second from the Darracq, which led the Pullman by nearly a mile, the Kline-Kar dropping out at the sixth mile with tire trouble.

The timing and scoring arrangements were the best ever seen here, Paul B. Huyette, official timer, having inaugurated a new system which worked perfectly. In the six-hour race the laps were scored with the aid of a battery of seven odometers—one for each entrant—and at each mile the time was set forth on a score-board in black figures on white cards. The summaries:

MATCH RACE, 10 MILES

No. Car	Driver	Time
1—Mercer	J. Sherwood	12:28 2-5
2—Otto	G. H. Jones	Did not fin.

10 MILES, 161 TO 300 CU. IN.

1—Pullman	Harvey Ringler	11:33 2-5
2—Otto	G. H. Jones	12:12
3—Ford	Frank Kulick	12:14 4-5

10 MILES, 451 CU. IN. AND UNDER

1—Pullman	Harvey Ringler	11:30
2—Ford	Frank Kulick	12:10
3—Kline-Kar	C. C. Fairman	Did not fin.
4—Otto	G. H. Jones	Did not fin.

10 MILES, 750 CU. IN AND UNDER

1—Knox	Oldfield ..	11:34 4-5
2—Darracq	Ben Kerscher	11:35

Some 1911 Automobiles

VETERAN autoists, especially those who make it a practice to have a new automobile every year, find themselves somewhat at a loss this season, due to the fact that they are not offered a wide opportunity to ascertain with any degree of certainty just what the 1911 cars will be like. This is as it should be, and the probabilities are that it is only a matter of two or three years at the most when the "annuals" will disappear so that when a good automobile is selected by a purchaser it will remain good until it is worn out in the regular way. The idea that an automobile, like a costume from Worth, should cease to be of value because the season changes, is perfectly absurd, and it is believed that the new designs of bodies, some of which are presented here for the first time, are sufficiently standardized and so well along stable lines that an autoist will scarcely have to buy a new car next year simply because it may be next year, or because a change in body work was found to be necessary on the ground of imperfections in the earlier effort. Past practice, with its rapid-fire variations, frequently hid serious defects under a

DISCUSSING SUCH MAKES AS PEERLESS, PACKARD, CHALMERS, INTER-STATE, AND FRANKLIN, FROM THE BODY AND POWER PLANT POINT OF VIEW, DEPICTING THE TREND

guise of a change in style, for the sake of style, conveniently forgetting that there was a grave necessity at the bottom of it all.

It is believed that the supporters of the industry have always laid too much stress upon questions of appearance, and failed in many cases to grasp the significance of quality from the point of view of the mechanism. As an illustration of what not to do when it comes to buying automobiles, a $3,000 body is scarcely a fitting crown for a $1,300 chassis. This may be an apparently far-fetched presentation of an absurd situation, but such things have happened in the past. In looking over the bodies of the several makes as here presented, it will be observed that they are in better taste than formerly. The cost of the body work is commensurate with the chassis, and a better adjustment of the relating costs will be found. This may not seem to be a sufficiently important point to draw out a protracted discussion, but as the history of the automobile is written, it represents far more than surface indications would seem to show. The evolution of the automobile represents a long struggle with the mechanical phase of the situa-

tion, and a slow but sure series of modifications of body work, they being the result of mechanical changes. Originally, bodies were mere adaptations of those in common use on horse-drawn vehicles, employed, perhaps, because of the designers' lack of experience. In time the body situation modified, and for 1911 we have the enclosed types of bodies, some along torpedo lines, others conforming to gunboat styles, but all suggesting the presence of a machine, rather than a relation to the old "rig."

If it may be taken for granted that the enclosed form of body simplifying the torpedo or the gunboat idea is taking root, and indicating that it is a permanent institution, the fact remains that limousine types are being perfected and amplified. The illustrations given with this article of enclosed types of bodies represent the best interpretation of the creative genius of the pure artist, coupled with the strength which comes by taking advantage of the designing ability of a trained engineer, advanced a step through the handiwork of the artisan, and brought to finality by depth and scope of finish, calling into play appropriateness in the selection of groundwork and color, beyond the dream of the carriage maker at his best, and in the fullest conformity with the exigencies of automobile service.

Mechanical Refinements in the Finer Sense Only

Taking the Peerless 1911 power plant with a view to comparing 1910 with 1911, the new line as announced includes three dis-

tinct models as follows: Model 31 with a 30-horsepower, four-cylinder motor, having a 5-inch bore and 5-inch stroke; Model 32 with a 50-horsepower, six-cylinder motor, with a bore of 5 inches and stroke of 5 1-2 inches, and Model 29 with a 20-horsepower, four-cylinder motor, with a bore of 4 inches and stroke of 4 5-8 inches. As an indication of the flexibility of the plan considered by the Peerless Motor Car Company, of Cleveland, Ohio, ten distinct types of bodies are regularly available for the three types of chassis. It has been the claim of this company all along that it aimed at standardization and avoided to the greatest possible extent the introduction of glaring innovations, so that it will come as no surprise when it is said that beyond making such refinements as a year's experience might properly suggest, the 1911 product is substantially the same as for 1910.

Taking up the refinements of the year, the most important one, perhaps, comes in the form of an air compressor pump for inflating tires. This pump is a prototype of a four-cylinder automobile motor, and is secured to the front end of the gearset under the front deck-boards. It is driven by an extension of the lay shaft of the gearset. In order that the pump may be thrown into gear at will, a suitable clutch is interposed. Air is conducted from the pump through brass tubing, terminating in a coil of hose of sufficient length to facilitate the work, and the clutch for the air pump is operated by means of a rod and lever which extends through the side member of the frame at a convenient

The Clark Power Wagon

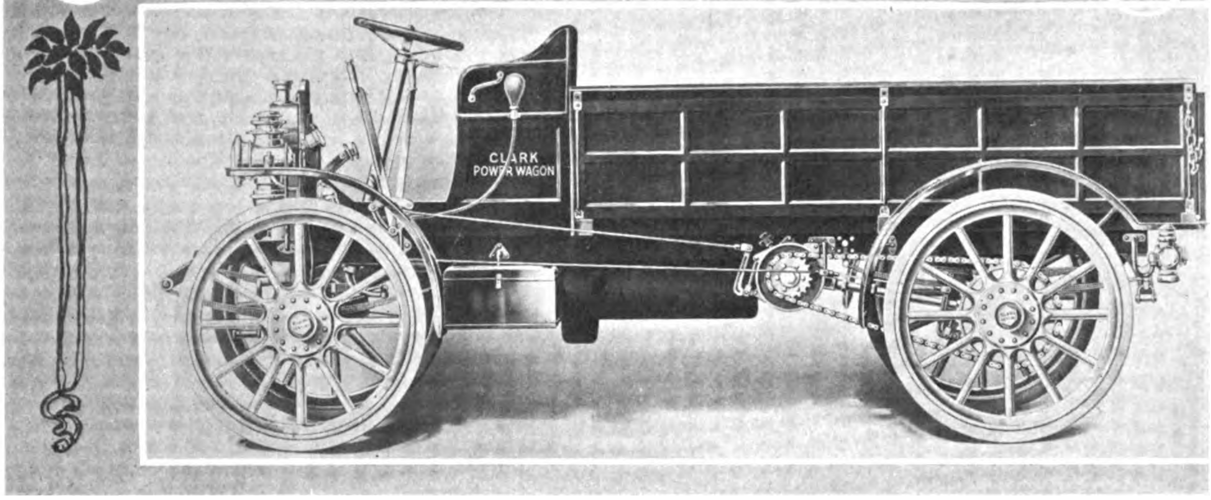

Fig. 1—The Clark Power Wagon, fully equipped and ready for service

LEADERS in the automobile field are rapidly reaching the conclusion that power wagons will ultimately become the mainstay of the industry, it being the case that "long hauls" are now made advantageously in this way and heavy inroads are being made in the "short haul" work. During the pioneer days of the commercial car the plan was more or less hampered by considerations which had nothing to do with the enterprise. The plants devoted to the manufacture of automobiles were so thoroughly engaged in the production of pleasure vehicles that there were no facilities left to be utilized in other work. In addition to lack of facilities the industry was confronted by a famine of technically trained men, and even the artisans were in numbers insufficient to supply the demand. Many attempts under the conditions in the direction of commercial car production were rendered futile, and the public at large reached the false conclusion that however good the automobile proved to be in pleasure pursuits, it was lacking in stamina.

It is no longer necessary to put any effort into persuading merchants that they must use the automobile for long hauls, and all that remains is to afford them the time in which to readjust conditions (one of which is to get rid of a circuit of horses), when short haul work will be taken care of through the medium of power wagons especially designed to successfully cope with the problems involved. It is recognized that the light delivery wagon, as it will have to meet competition, must be thoroughly good in every way, and its flexibility must be greater than that possible under ordinary conditions; moreover, the cost of maintenance will have to be kept down below that which seems to be true with improvised delivery wagons.

Encouragement is not hard to find if it is sought after in the quarters where it seems to reside in plenty; it is not in the path of wisdom to overlook the fact that with animal transportation the service is well organized and conditions of economy obtain at every point. Considering the service to be expected from power wagons, the conditions are not so fortunate. As a rule, the men who are devoted to the care and maintenance of animal-drawn vehicles are impressed into the other service when it is instituted, and in addition to a certain antipathy, due to their love for horses, there is the other side of the question involving not only lack of mechanical skill, but the probability of incapacity for acquiring a reasonable measure of the same.

The Clark Power Wagon Company, with a well-equipped manufacturing plant at Lansing, Mich., having spent many years in the manufacture of wagons in general, made it a point not to transfer its allegiance to power wagons until the time was ripe. It is a well-established fact, if not a principle, that an invention ahead of its time, however good it may be, sinks to the level of a common nuisance, and it was foreseen by the company that it could better afford to continue its regular line of work, supplying its clientèle as dictation required, studying the automobile situation in the meantime, hoping thereby to arrive at a wise and fitting conclusion, and after going over the mätter at the greatest possible length two harmonious ideas took form: one was that the company had conducted a sufficient investigation to permit it to build a good power wagon, and the other takes into account the positive demand for wagons of this character.

It will be understood that the body work in the majority of cases must be contrived in view of the service to be rendered. Under the circumstances, the company devotes a part of its energies to the building of special bodies and is equipped to turn them out with great promptness after a fitting conclusion is reached in which the customer is consulted and is advised in the various ways. Fig. 1 depicts a standard form of the power wagon, a body which is much in vogue and may be had with or without a top. With the understanding that there is no limit to the types of bodies to be had for the asking, this phase of the situation will be subordinated to the mechanical side of the subject, which is of far more importance. Fig. 2 is a plan of the chassis showing a 2-cylinder motor of the opposed type located athwartships at a point on the chassis which brings the motor directly under the driver's seat. The radiator is located in front on the center line of the front axle, and independent water connections are made to the respective cylinders of the motor. The flywheel F1 is at the back of the motor, houses a cone clutch, and power is transmitted from the same through universal joints U1 to the transmission gear G1, thence to the jackshaft J1 with a bevel drive and differential gear enclosed. The jackshaft unit is self-contained, and is bolted up to the chassis frame, bringing the sprocket pinions S1 and S2 at a point well in front of the rear axle, but in line with the sprocket drums D1 and D2, which are bolted to the rear wheels, details being given elsewhere. The exhaust from the two cylinders of the motor passes back to the cross connections E1 and E2 to the muffler M1, bringing the same to the rear of the chassis frame and assuring that the exhaust will be cool, smokeless and noiseless, and affording the advantage of straight pipe connections without interfering with the play of the rear axle. The steering linkage L1 comes to the rear of the front axle, is protected thereby, and the link to the steering post is straight and long enough to avoid cranky steering action.

Main Points in the Power Plant Construction

The plan of the motor as shown in Fig. 3 presents the cylinder S1 with the water connection removed, showing the valve springs S2 and S3 and the tappet adjustments T1 and T2 with long guides G1 and G2 for the valve lifts V1 and V2, engaging the cams C1 and C2, which are integral with the camshaft which floats in bearings B1 and B2, taking power from a pinion on the crankshaft to the gear G3. The other cylinder S4 is shown in section, including the piston P1. There are four packing rings to maintain tight compression, one of them being below the gudgeon pin G4. The connecting rod C3 is of the I-section and has a long bearing on the gudgeon pin, which, together with other nice features of design, represents the foundation for the sanguine hopes of the designer. The flywheel F1 is relatively massive, this being an important matter in commercial work, and the magneto M1 is located at the other end, being driven by an extension from the camshaft through a universal joint U1.

Substantial Crankshaft Relied Upon for Service

Referring to Fig. 4, which is a side view of the motor in part section, the valve V1 is clearly brought out and the guide G1 is shown. All valves are of the bevel seat type, of the same size, and in diameter equal to half the diameter of the cylinders, thus assuring a full charge on each suction stroke, and exhaust free from back pressure, resulting in a well-established torquing moment and a full measure of power. The connecting rod C1 is shown completely in this view, and the halftime pinion P1 is shown in part indicating its relation to the halftime gear G2. The crankshaft C2 is a well-designed drop forging of special steel and the crank pin C3 is shown in section, indicating that the bearings are large, this being an extremely important detail in commercial service. Oiling is done positively by a pump P1 located in a well which is bolted up to the crankcase and the pump is driven by a vertical shaft S1, which takes power from the crankshaft. Among the other points worthy of mention are the symmetry of design, large water-jackets, uniform sections of metal at every point, castellated nuts with cotter pin locking, and just the refinements that are now standard with engineers of competence.

In order to fully appreciate the extent to which this motor has had the attention of the designer, it will be necessary to make a critical examination of Fig. 5, which is a longitudinal section in the plane of the crankshaft, presenting a substantial front main bearing M1 which may be removed by taking out the bolts B1, B2, etc., around the periphery, and if it is desired to remove the crankshaft, the same operation may be performed for the main bearing M2. The rear main bearing carries the weight of the flywheel F1, and is made relatively long and of greater diameter than the bearing M1. With the idea of inducing additional service security the method of oiling is looked after with the utmost care. The oil enters at O1, and after flooding the bearing, passes out under pressure to the slinger on the shaft S1, where it is thrown by centrifugal force to the cavity C1, whence it flows back through the channel C2 to the crankcase C3, thence to the oil-well O2. The method of driving the oil pump is clearly brought out in this section, showing a worm W1 driving the pump gear G1. The timer T1 is driven by a bevel set B3 taking power from the camshaft, and the magneto M3 is maintained in proper alignment, due to the accuracy with which the support S2 is machined. The clutch C4 is of large diameter, made of aluminum and dished, has a leather facing L1 with cork inserts C5. The clutch spring S3 is of large diameter, and housed in. An adjusting nut N1 permits of varying the pressure of the spring, and the thrust is taken by a suitable thrust ball bearing.

Transmission Includes Universal Joints

Referring to Fig. 6 of the transmission gearset, power is taken by the universal joint U1, the same being pressed up on a taper T1, by a nut N1. The universal joint is of large capacity, and being fastened onto the shaft in this secure manner, it is permitted to serve for a long time in a proper and satisfactory manner. This shaft is supported by two annular type ball bearings B1 and B2; they are spaced at a considerable distance apart and are large for the work. At the point of engagement for high gear the jaws J1 are of substantial design, and instead of the two shafts telescoping at this point, an annular type ball bearing B3 is used. The other end of the shaft is supported by the ball bearing B4, and a thrust ball bearing B5 is also placed just back of the bevel pinion. The lay shaft, which is back of the main shaft shown, also rolls on annular type ball bearings. Power is transmitted to the bevel pinion B6 to the bevel gear G1 and is translated by the bevel differential D1 to the jackshafts J1 and Y2, thence to the sprocket pinions. Annular type ball bearings B7, B8, B9, with a mate to B7 on the opposite end, are placed to handle the jackshaft load and a ball thrust bearing B10 is placed back of the bearing B8 to resist the thrust of the bevel gear G1. At every point in this system, the proportions of the parts are in accord with the latest and most approved practice, and in addition to using annular type ball bearings of authenticated ability, the materials employed in the shafts, gears, and other parts are selected for their kinetic characteristics.

In order to show the location of the lay shaft with respect to the main shaft in the transmission gear system, it is necessary to present the section Fig. 7, which is at right angles to the section

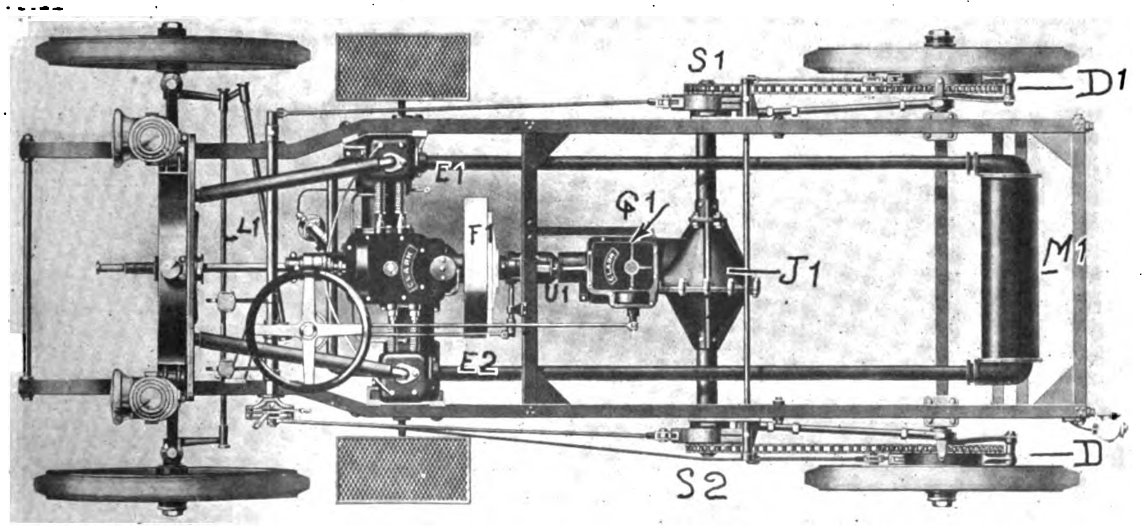

Fig. 2—Plan of the chassis, showing the nesting of the power plant

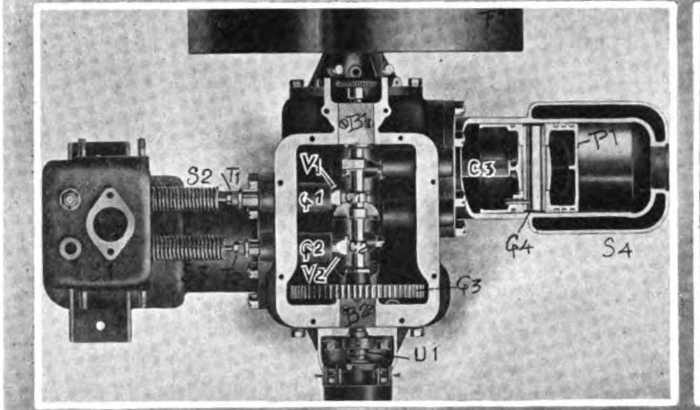

Fig. 3—Plan view of motor and sectional view of cylinders

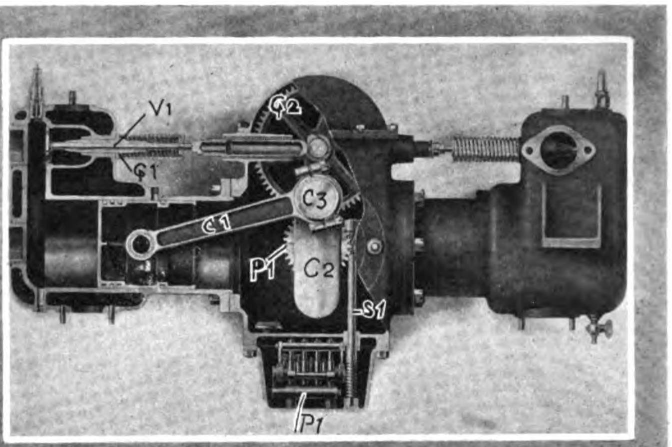

Fig. 4—Front view of motor; sectional view of cylinders and oiler

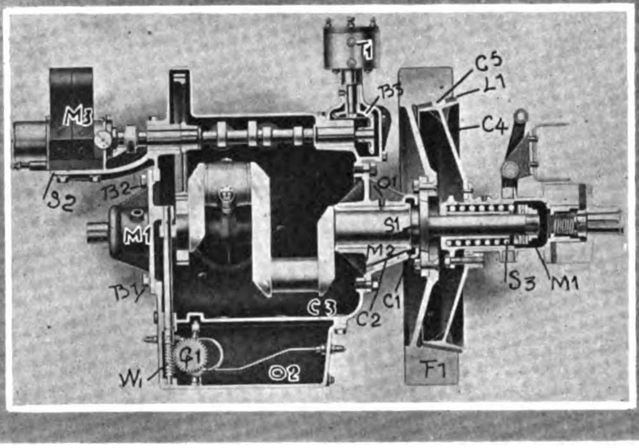

Fig 5—Sectional view of motor, oiler and clutch

Fig. 6. In this section the lay shaft L1 is in the plane of the main shaft M1 directly below. The relations of the gears are clearly indicated, and the annular type ball bearings before mentioned as belonging to the lay shaft are shown. This section also presents details of design that are not so clearly brought out elsewhere, as, for illustration, the ball bearing housings are presented, and the method of locking the ball bearings on to their spindles is shown with great clearness.

Fig. 8 shows the L-section front axle, details of the steering knuckles, taper roller bearings, methods for lubrication, and an indication of a sufficiently liberal use of metal to sustain in commercial service.

Harmony of Relations Aimed At

The two-cylinder motor is expected to furnish all the power that can be advantageously used in the service of this character, and the opposed type is selected in view of its favorable history in commercial pursuits, but in order to assure a sufficiency of motor performance the cylinder bore is made 5 inches with a stroke of 5 1-2 inches. Next in line on the road to smooth action is the large and suitably fashioned clutch, it being the case that cork inserts have the facility of permitting of slipping, if it is found to be advantageous, without burning the clutch. From the clutch to the sliding gear there is a further bid for harmony through the use of the universal joints as previously shown, and the well-designed transmission gear of the sliding type with two speeds forward and reverse, being progressive in action, eliminates the necessity of using a great measure of intuition in the management. The power being translated from the sliding gear system to the rear wheels by means of an efficient and stable side chain drive leaves little else to be desired, and it is worth pointing out, while the opportunity affords, that this school of design is quite free from harassing detail from the point of view of maintenance. The brakes are of suitable design and efficient for the purpose, and the tire equipment is either solid or pneumatic, depending upon the service to be rendered. The wheel base is 102 inches, and 36 x 2 1-2-inch solid tires are used. The regular price of $1,450 includes the express body as shown in Fig. 1. If the purchaser selects pneumatic tires they will be 36 x 3 1-2-inch and cost $50 extra. If the express body is to be supplanted by a special body, the chassis will be figured in at $1,375. The tool, tire, and regular lamp equipment are included in the chassis price. The company has a well-equipped plant and is making rapid strides in the direction of the production of the cars, of which it proposes to turn out enough to satisfy every investigated demand; but care will be taken not to put cars into service for which they are not intended.

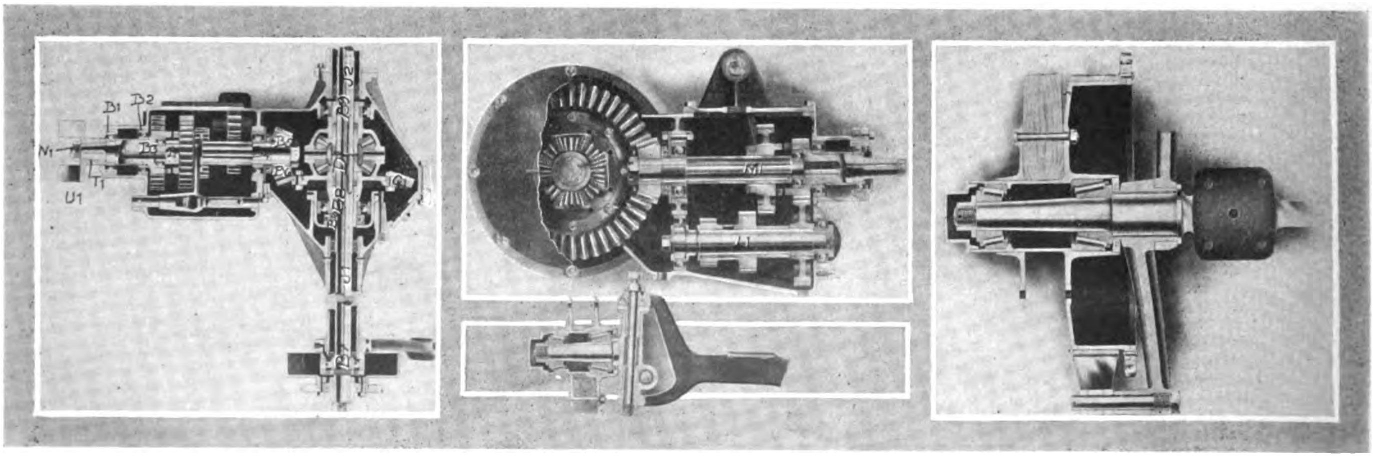

Fig. 6—Sectional plan view of transmission, differential and jackshaft. Fig. 7—Sectional view, side elevation of transmission and differential. Fig. 8—Front axle, presenting sectional view of steering knuckle pin, bearings, and hub. Fig. 9—Sectional view of rear brake drum and wheel bearings

Body Rejuvenation

DESCRIPTIVE OF REJUVENATED E-M-F "THIRTY" BODY AFTER IT IS CHANGED OVER FROM THE REGULAR TOURING TYPE TO CONFORM TO THE CRUISER IDEA, INCLUDING WORKING DRAWINGS.

LAST of a series of working drawings which were offered for the purpose of showing autoists how old touring bodies might be reconstructed at small cost, bringing them up to the latest idea along cruiser lines, using the old body in the new work, without having to alter the same in any way, excepting to provide a new dashboard and utilize a pillar of bent wood in securing the new fore-door in place. Fig. 25 is a side elevation of the E-M-F "Thirty" car as it would appear were it converted in accordance with the working drawings as presented in Figs. 26, 27 and 28. Fig. 26 shows the shape of the new fore-door, and glancing at Fig. 25 it will be observed that it is in the style of the door of the side entrance of the tonneau, with hinges and hasps to match. Referring back to Fig. 26 the dotted lines show the framing, allowing for a door 17 inches wide in the clear, hinged in front, and in harmonious relation with the old body. There is of course no door provided for the right side of the car, and as Fig. 27 shows, the emergency brake lever falls to the outside of the body line, but the sliding-gear lever passes through the body, a slit being provided for the purpose, thus bringing the sliding gear lever to the inside. The overhang of the dash is 4 1-2 inches amidships, is 34 inches across, and 24 inches high at the low point. The flare of the overhang would come in the natural course of construction and would be made to suit the eye. The plan, Fig. 28, will give an excellent idea of the finished result, and as before stated, for other efforts along this line, it is important to refinish the old body in such a way that it would not be possible to distinguish as between the newer and the older portions after the body is painted. This demands a little care on the part of the finisher, who should show some competence.

Vaporization of Gasoline Discussed

Investigation seems to have shown that the gasoline out of the nozzle is more likely to be in stream formation than as a spray, and the stream is made up of a solid portion surrounded by torn-off globules, some of which are relatively large and the rest grading down to vapor size. Observers have been deceived by the outer wall of vapor which tends to hide the solid central stream and the larger chunks of gasoline which form between the solid stream and the vapor-like outer wall. The claim is almost invariably made that perfect vaporization is brought about by carbureters—such results are not always realized.

Questions

CONSIDERING WIND RESISTANCE; SPEED ON CURVES; EFFECT OF BANKING; CALCIUM CARBIDE; PRESSURE, VOLUME AND TEMPERATURE OF GASES; AUTOMATIC VALVES AND FORMULAE FOR SPRINGS; ADVANTAGE OF STUB TOOTH GEAR.

[193]—Is it necessary to consider wind resistance in connection with the power required to drive the average runabout type of automobile?

No. The wind resistance is scarcely a measurable quantity at 20 miles per hour, is not more than 3 pounds per square foot at 30 miles per hour, nor does it reach 10 pounds per square foot until the speed is equal to 52 1-2 miles per hour in round numbers.

[194]—How is wind resistance determined?

A formula for use in approximating the power required to overcome wind resistance is given as follows:

$$HP = \frac{PA\ (M\ 5{,}280 \mid 60)}{33{,}000} = 0.96\ PAM$$

In which

HP. = horsepower required to overcome wind resistance.
P = pressure of wind in pounds per square foot.
A = front area of body in square feet.
M = speed of car in miles per hour.

Numerical example:

Assuming a car with a front area of 10 square feet and a speed of 60 miles per hour, the power required to overcome this wind resistance will be:

$$H.P. = \frac{13 \times 10\ (60 \times 5{,}280 \mid 60)}{33{,}000} = 20.8$$

It is not believed that this formula will hold out for all ranges in speed, nor can it be said with certainty that the front area total will be correctly stated if the areas of all the parts without respect to shape or location are figured in on the same basis. In all probability, the most certain way to ascertain the amount of power required to overcome wind resistance is to take a certain car and with suitable instrument under road conditions measure the power required.

[195]—In dealing with the questions of car performance on a curve, it would be interesting to know not only the maximum speed at which it is safe to drive, but also the effect of banking, and of declination. Can you state in a comparative way the effect on car under the three conditions?

On a level hard road with a curve of 100 feet radius, the turning over speed is about 38 miles per hour. On an embanked curve, considering the same radius, if the inclination is 10 degrees, it will be safe to travel at a speed of 47 miles per hour, but if there is a declination instead, and the same amounts to only 5 degrees, the safe speed will be about 23 miles per hour. These figures are sufficient to indicate to a driver of prudence that it is extremely dangerous to round a curve if there is a declination, whereas an inclination (banking) renders driving quite safe, at the same time, it must be remembered that increasing the radius of the curve adds materially to the measure of safety.

[196]—During the warm days I noticed that my tires become harder and the tire pressure actually increases, probably on account of temperature. Is there any danger of blowing up the tires?

The real danger lies in not maintaining a sufficiently high tire pressure. None of the hand pumps to be had upon the market as used in automobile work are capable of affording a pressure higher than that which may be safely sustained by tires. A 34 x 4 tire, for illustration, should have a pressure of 80 pounds per square inch as a minimum, and if a tire such as this is inflated to 80 pounds per square inch during the cool of the morning, when the temperature increases, as it will following service and the heat of mid-day, the pressure in the tire will increase considerably, but there is scarcely any danger of obtaining a pressure from these causes greater than the tire is capable of sustaining. If a tire is inflated to 80 pounds per square inch cold, the pressure will increase to about 98 pounds per square inch under the worst conditions likely to be encountered in the summer time. The tire may ride a little hard with this higher pressure, but it will last longer than would be true were the pressure to fall below 80 pounds per square inch. Tires on front wheels may be permitted to run at a somewhat softer pressure, but it is a dangerous experiment.

[197]—At my country house, where I keep five automobiles, I have solved the gasoline problem by purchasing a commodious steel tank, and properly installing the same so that I buy a wagon-load of barrels of gasoline at one time, getting the lowest price per gallon and on the delivery as well, but I have not succeeded in solving the carbide problem. I am purchasing it in cans at too high a cost. Is there not some better way?

After manufacture, the fused carbide is run through crushers just as coal is crushed, and the result is several sizes of carbide which are named in the same way as coal. Lump carbide is the largest size, ranging between 3 1-2 and 2 inches. Egg carbide is the next size, and ranges between 2 and 1 1-2 inches. Nut carbide follows in turn, ranging between 1 1-4 and 1-2-inch, and the size that you would probably want is called "quarter" carbide, ranging in size between 1-2 and 1-4-inch. Those who make a a practice of canning carbide, procure it in tight drums of various sizes, and at a lower price than that ruling for small lots.

[198]—What is calcium carbide composed of and how is it made?

The base of acetylene (calcium carbide) is made in the electric furnace from lime and coke, fused at a temperature ranging between 5,000 and 7,000 degrees Fahrenheit.

[199]—Will you please state the chemical composition of a grade of nickel steel that you would recommend for cementing purposes?

Nickel	Carbon	Silicon	Sulphur	Phosphorus	Manganese
4.5	.10-.15	.15-.20	.03-.04	.03-.04	.30-.40

[200]—What is the variation of volume and temperature with compression?

Assuming that no heat is added or subtracted, the tabulation as follows will hold:

VARIATION OF VOLUME AND TEMPERATURE WITH COMPRESSION

Gauge Pressure	Volume	Temperature
0	1.000	60
2	.910	80.4
5	.810	106
10	.690	145
20	.543	207
30	.454	252
40	.393	302
50	.350	339
75	.276	420
100	.232	485
115	.213	518
130	.197	550
145	.184	580
160	.172	607
175	.163	632
200	.149	672

[201]—In a carbureter, what is the measure of the force of the float in the bowl?

The vertical upward force, in other words the buoyancy, will be equal in weight to the weight of the liquid displaced.

[202]—The opinion obtains in some quarters to the effect that the automatic inlet valve idea in motor designing is less complicated than when a positive method is employed, such as that involving the use of a cam shaft, valve lifts, springs, etc., but practice seems to will to the contrary. What is the matter with the automatic inlet valve?

Force is required to open the valve. This force is only available through suction, and it is at the expense of a more completely filled cylinder. The power of the motor is due to the weight of the mixture taken into the cylinder, and any obstruction in the intake is bound to reduce that power. An automatic valve may be looked upon as one of the most efficacious obstructions that can be devised for the purpose, and while it permits mixture to enter the cylinder after the valve is opened by the difference in pressure between that which resides in the cylinder and that in the atmosphere without, it is, nevertheless, at a great cost in power.

[203]—What are the proportions of the Brown & Sharpe involute form of teeth as used in transmission work?

PROPORTIONS OF INVOLUTE FORMS OF TEETH

Whole depth of tooth $= \frac{2.157}{P}$

Depth of tooth above pitch line $= \frac{1}{P}$

Working depth of tooth $= \frac{2}{P}$

Depth of tooth below pitch line $= \frac{1.157}{P}$

Clearance at root of tooth $= \frac{0.157}{P}$

Thickness of tooth at pitch line $= \frac{1.57}{P}$

Width of space $= \frac{1.63}{P}$

Back lash $= \frac{0.6}{P}$

P = Diametral pitch of gear.

[204]—Is there a formula of any kind that will permit of scientifically designing half-elliptic flat plate springs so that they may be depended upon under the most severe conditions of service?

There are complex methods of arriving at fairly safe conclusions, provided the material used is up to some known and recognized standard. The usual method, however, is faulty in that it fails to take into account the fact that a given amount of material should not be worked beyond a certain limit if it is to last for a long time. One formula recommended for what is known as the safe loading, is: Let,

B = Width of plate in inches.
T = Thickness of plates in 1-16 inches.
N = Number of plates used.
S = Span of spring in inches.
C = A constant = 11.3.

When,

$$\text{Safe Load in tons} = \frac{B\,T^2\,N}{C\,S}$$

To determine the amount of the deflection in inches, per ton of load, the formulæ as follows has been recommended: Let,

D = Deflection in inches per ton of load.
L = Span of spring in inches.
C = Constant — 40,000.
B = Width of plates in inches.

When,

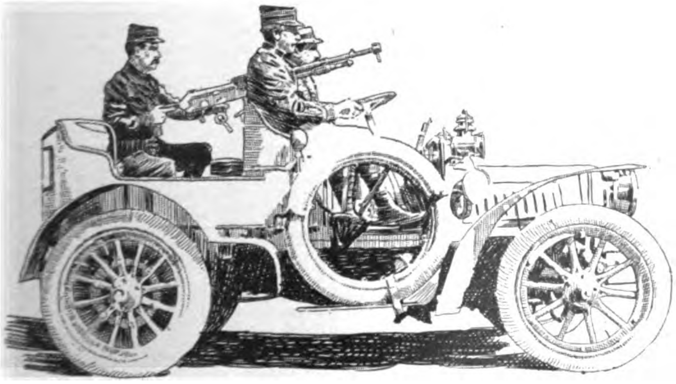
$$D = \frac{L^3}{C\,B\,T^3\,N}$$

Unarmored War Car

DR. ROBERT GRIMSHAW TELLS HOW THE FRENCH GOVERNMENT DURING THE MOROCCAN TROUBLES EXPERIMENTED WITH THIS OUTFIT WITH A VIEW TO ITS USE IN THAT CONFLICT

In Europe the military automobile has been undergoing many developments and alterations as applied in the service of the various branches of the army—from carrying the general staff conveniently along the best roads, to hill-climbing, for transportation of men and ammunition; from automobiles with heavy armor-plating and mounted with comparatively heavy machine guns, to others which constitute the more humble, "mute and inglorious," but none the less necessary, field kitchen. The latest form is the unarmored machine-gun auto.

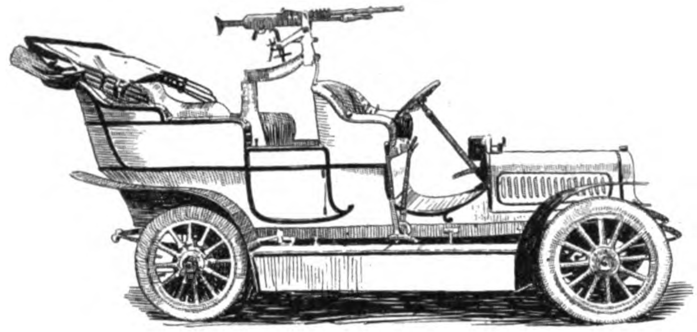
The first advantage derived from the automobile for war purposes was considered to be its emancipation from the track necessary for the locomotive—this giving it necessarily in great part the carrying and towing capacity of the latter, without the limitations of direction which are necessarily inseparable from the "iron horse" of the last century. As a means of offence, however, the railless self-propelled vehicle had its defects—being, of course, somewhat restricted as regards two things: the amount of armored protection which it could carry and the caliber of gun with which it could be equipped; that is, it was either offensively or defensively weak, or both. So the armored auto has not done all that the manufacturers hoped, or the military authorities wished.



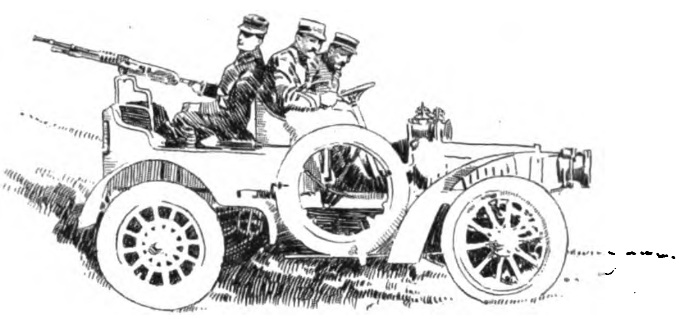
French unarmored automobile war outfit—a Hotchkiss gun mounted on Panhard truck; Capt. Gentil driving

In October, 1905, the German War Department had an armored auto submitted to it by a private firm, on the latter's own initiative. The tests, made before the representatives of the Ministry of War and the troops, did not receive the encouragement that the builders hoped. This vehicle was steel-plated even to the wheels—for, of course, like Achilles, who (if mythology belie him not and do not deceive us) was vulnerable in his running gear—the auto with "pneumatics" would be an easy prey to the enemy if its tires should happen to be burst by sharpshooters or from other causes. The Austrian Ministry of War also made tests in the same field of investigation—in this case with a Wiener-Neustadt Daimler driven on all four wheels. This armor-auto—if I may be allowed the expression, and really I should not—could quite conveniently, thanks to its four-wheel drive, cross plowed land and take hills, on which the ordinary auto, even of lesser weight, would stall. Here, instead of protecting the tires by steel armor-plate reaching nearly to the ground, solid rubber tires were used.

The heaviest caliber of machine gun which it has been considered practical to use is five centimeters, or a trifle short of two inches. The great disadvantage of the armored auto, however, is that it offers to the enemy a much better target than the average horse-drawn field-piece of equal or greater destructiveness. This led to the demand for an armor plating much more resistant, and consequently much heavier, than the shield protecting the horse-drawn machine gun. But this armor materially reduces the offensive power of the wagon. For this reason the idea has gradually been adopted to dispense entirely



Ready to sweep the country ahead with the automobile gun



The gun swung to the rear to keep off pursuers

with the armor and let the occupants simply "take their medicine." Those manning torpedo boats have practically to do this; the officers of the British Army stand when under fire, although their men lie down; why not the auto-gunners? At any rate the result of the idea or the return to the old one, in warfare, is the auto shown herewith, and which is intended to serve in cases where mounted infantry would accompany the cavalry. Should either the running gear or the driving mechanism be put *hors de combat*—which does *not* mean "war horse," as the schoolboy translated it—the only resource would naturally be to spike the gun, or perform the equivalent operation which would render it useless, and abandon the entire rig. The military authorities have not yet decided whether it would not be better to use, instead of the type here shown, motor-bicycles with one man each, suitably armed.

The intermediate step between the entirely unprotected auto here illustrated (the cuts are taken from the *Leipziger Illustrierte Zeitung* for January 16) was the Opel-Darracq machine shown at the last Berlin Automobile Exhibition, and which had only a belt of armor, so that it was entirely unprotected against projectiles falling from above, as where downward fire is directed against it from a hilltop, or shot fired at great elevation makes the corresponding curve in descending, or where a shell bursts in the immediate neighborhood. In order to enable the occupants better to view their surroundings, this vehicle had in the armor belt hinged portions which could be let down to give unobstructed view.

At the recent, most unsuccessful, German Military, Marine and Colonial Exhibition in Berlin there were exhibited alongside of the fully armored auto of the Eckhardt firm, of Zella St. Blasii, the vehicle as shown herewith, and in which, figuratively speaking, not merely the Achillean heel, but the whole Achillean body, is entirely unprotected. The drive is by means of a friction coupling to the change gear, and thence to the rear wheels. There are seats for four persons, and the machine gun is swivelled on a special "lafette"—carriage it could not be named—between the front and the rear wheels in such a manner as to command the entire circle without turning the auto. It is easy to see that such a vehicle would have special value for colonial warfare—meaning, in this sense, war against unmounted savages, insufficiently equipped with weapons and relying on their numbers. This would point especially to its value for certain African conditions; and also, if we leave out the reservation about cavalry, for settling the Moroccan question by force of arms. Whether or not the French Government will do in this respect what it did before with regard to the captive military balloon—namely, postpone its adoption until too late—remains to be seen.

In the meanwhile there went to Oran in December on the steamer *Russie* a Panhard "auto-mitrailleuse," which was at once sent by train to Tlemcen, and for the service of which a detachment of ten men under command of Captain Gentil was detailed. Eastern Morocco would seem to be very well suited for operations with such an auto—perhaps better than the Casablanca district, to which we hear that a similar auto will be sent. These vehicles resemble considerably the light military auto shown at the before-mentioned triple-named exposition by the Rheinische Metallwaren und Maschinen Fabrik.

Fig. 2 shows the French machine gun ready to sweep the field in front; in Fig. 3 the attack is to the rear.

Testing Steel

FOR IMPACT, BENDING, ETC. FINAL INSTALLMENT OF A PAPER PRESENTED BY BERTRAM BLOUNT, W. G. KIRKALDY AND CAPT. H. RIALL SANKEY BEFORE INSTITUTION OF MECHANICAL ENGINEERS (GREAT BRITAIN).

IN the issue of THE AUTOMOBILE of June 23 was printed the first installment of the article of which these tables form a fitting conclusion. The authors presented in a telling way the methods employed and the conclusions reached in the exhaustive tests of various types of steel furnished by British makers. To insure accuracy in the impact tests a falling-weight apparatus was designed. A series of tensile tests were carried out in the usual way on test-pieces made in accordance with the provisions of the British Standard specifications. The methods of analysis employed were those usually accepted by steel chemists. Tensile-impact and repeated-bending tests, as carried out by the experimenters, are fully described in the course of the paper, and the conclusions arrived at are given in the accompanying tables in the form of a comparison of the results obtained. These tables show, among other things, the elastic limit, yield stress, breaking stress, percentage of elongation and character of fracture in the tensile tests, and the energy absorbed in the impact and bending tests.

Letters

QUERIES OF TIMELY INTEREST FROM READERS OF "THE AUTOMOBILE," INCLUDING COMPLEX RELATIONS OF FUEL AND TIMING; SOME FACTS IN RELATION TO A DANGEROUS PROPOSAL; LOOKING FOR TROUBLE IN THE MOST DIRECT WAY; RATHER POINTED QUESTIONS ABOUT IMPORTANT MATTERS; RADIATOR MAY BE OF INSUFFICIENT CAPACITY.

Will Some Expert on Leather Furnish a Recipe?

Editor THE AUTOMOBILE:

[2,342]—Will you kindly tell me in your column "Letters Interesting" what I can do to the leather of a new automobile to prevent the black from ruining one's clothing. Have tried washing with ivory soap and rubbing dry with cloths. There seems to be an unlimited supply of this black stain in the leather. I have had my car eight weeks, and by chauffeur's coat, although washed every week, is still blackened as at first. Is there not some kind of a varnish that could be put on the leather to prevent this? The men in the leather business around here cannot help me.

Bethlehem, Pa. SUBSCRIBER.

Many Fallacies in the Automobile Business

Editor THE AUTOMOBILE:

[2,343]—Is it possible for a 4-cylinder, 4-cycle engine to overheat, with water in the radiator up to the cap? Will ground flax-seed harm the radiator or engine? If so, what is the best way to clean both? Is a low-tension magneto considered as good ignition as a high tension? How can I remedy a magneto (low tension) if it does not spark on slow speed? I notice it will not run the engine as slow as batteries.

Brooklyn, N. Y. J. W. REEVE, JR.

1. An engine will overheat whether the water is up to the filler cap in the radiator or not, provided the conditions in the cylinder are such as to induce overheating, as incrustation within the combustion chamber, or if the exterior surfaces of the dome are crusted up, then, a poorly designed cylinder may heat up independent of the above situations.

2. Ground flax-seed or any other foreign matter in the circulating water should give you all the trouble you can possibly handle gracefully. If you want to keep out of trouble use pure water circulated vigorously, and run the motor so that it will deliver the least possible amount of heat to the cooling system.

3. The best way to keep a radiator system clean is to have one that will not steam, so that the water will not have to be replaced, but if it must be replenished use pure water.

4. Either form of ignition system works perfectly well if it is properly designed, well built, suitably installed and cared for.

5. Time the magneto so that it will deliver a spark more nearly retarded than you now have it. We should think it ought to spark at about 18 degrees advance for the condition you name.

Stenographers Seldom Break Into Racing

Editor THE AUTOMOBILE:

[2,344]—Please inform me through the columns of your estimable paper the best way in your estimation to become connected with the racing team of some automobile factory. I am an experienced stenographer with a good knowledge of automobiles, and am anxious to get in the racing game. Would you think it advisable for me to endeavor to secure a position as stenographer with some factory which enters cars in races and maintains a force of drivers, and from that position try to become connected with the racing end? I noticed in an issue of your paper some time ago the statement that several prominent drivers now before the public were not over 18 years old. Could you kindly give me the names of some of them, and the make of cars they are driving? R. V. L.

Washington, D. C.

The way to become a racing driver is clear to the man who has qualities as follows:

(A) An eye for judging distance.
(B) The digestion of an ostrich (steady nerves and indigestion do not go together).
(C) A bland smile in the face of acute danger.
(D) The machinist trade at the ends of the fingers.
(E) Perfect familiarity with racing automobiles.
(F) A disinclination to do other kinds of work.
(G) Lack of acquaintance with John Barleycorn.
(H) No very great use for tobacco.
(I) Regular hours.

The qualifications which do not seem to be essential to the successful racing driver may be set down after a fashion as follows:

(A) Stenography and shorthand offers no great attraction.
(B) Youthfulness so accentuated as to be classed in the 'teens is all right for a juvenile hopeful, but some racing backers have a penchant for the veteran's experience.

Ideas Drift Along Parallel Lines

Editor THE AUTOMOBILE:

[2,345]—I have been reading your articles on "Automatic Stability in Aeroplanes" with very great interest. It seems to me that an end portion of the wing of an aeroplane could be so hinged that it would remain on the same level as the rest of the wing unless raised or lowered by a greater or lesser wind pressure. This movement would be arranged to tip the ailerons in such a way as to lower or raise the side struck by the wind, just according to whether the wind created a vacuum or the opposite, and thus maintain the stability of the machine.

A WOULD-BE INVENTOR.

New York City.

This is substantially the same arrangement as was proposed by the German engineer, Robert Conrad, in the article rendered in the June 2 issue of this journal, and illustrated in Fig. 1G, except that Mr. Conrad desires to employ the differential movement of two feeler-planes, on opposite sides of the machine, and considers it most practical to make these feeler planes highly sensitive and to have them operate ailerons or other control planes indirectly instead of directly; that is, he suggests to have them indicate to the aviator how *he* should control, because the feeler-planes could not be very sensitive and do work also. But they could operate an indicator by electric contact and thus release other forces, whether the aviator's or those of an auxiliary power device. With regard to the practicability of any arrangement of this order, we would reserve judgment until the apparatus was fully designed, and then once more until it was fully tried.

Wants Particulars of S. A. E.

Editor THE AUTOMOBILE:

[2,346]—I would be very much obliged if you could tell me the character of the Society of Automobile Engineers. I would like to know the qualifications for membership, and whether they maintain a junior membership as all of the great engineering societies do. I am a young man just entering the automobile business and would like very much to take out an associate membership in the society, and at least get their proceedings regularly as they appear.

St. Louis, Mo. B. O.

The Society of Automobile Engineers has a membership of well over three hundred, consisting of the leading engineers, designers and superintendents in the manufacture of automobiles, parts thereof, accessories thereto, and raw materials therefor.

It is the policy of the society to take into its membership all men interested in any field of automobile engineering, and qualified for S. A. E. affiliation.

The qualifications for the various grades of membership are as follows:

A *member* must be 26 years of age, or over, and have been so connected with engineering as to be competent as a designer or as a constructor to take responsible charge of work in his branch of engineering, or he must have served as a teacher of engineering for more than five years.

An *associate* must be 26 years of age or over, and have either the other qualifications of a *member*, or be so connected with engineering as to be competent to take charge of engineering work, or to co-operate with engineers.

A *junior* must be twenty-one years of age or over, and have had such engineering experience as will enable him to fill a responsible subordinate position in engineering work, or he must be a graduate of an engineering school.

Application blanks and literature explaining the present activities of the society may be secured from Coker F. Clarkson, General Manager of the Society of Automobile Engineers, 1451 Broadway, New York City.

Timing of the Franklin Air-Cooled Motor

Editor The Automobile:

[2,347]—In view of the practice of the Franklin Company which takes expression in the form of an auxiliary exhaust valve at the bottom of the stroke, I am bothered with the notion that the timing of the valves will necessarily be different from timing of valves in conventional types of water-cooled, four-cycle motors. Can you state just what the Franklin practice is?

Trenton, N. J. A. R. B.

It is the claim of the Franklin Company that about 70 per cent. of the total weight of exhaust product passes out through the auxiliary valves, so that the main exhaust valve is free to do the balance of the work; but this would not be ground for making any very considerable change in the timing of the exhaust valves and it was reported in the tests made at Sibley College, Cornell University, under the direction of Professor Rola C. Carpenter, that the timing as follows was used by Messrs. Evans and Lay in making these tests:

TIMING OF FRANKLIN AIR-COOLED MOTOR

(A) Inlet valve opened 5 degrees past center.
(B) Exhaust valve closed 12 degrees past center.
(C) Exhaust valve opened on center.
(D) Inlet valve closed 30 degrees past center.

Timing Exhaust Valve with Automatic Intake

Editor The Automobile:

[2,348]—What should the position of the crank be on a four-cylinder engine with automatic intake, when the exhaust valve commences to open and when it is closed? F. W. H.

Sidney, N. Y.

The exhaust valve opening should lead about 40 degrees with the piston on the down-stroke, and it should close with a lag of 10 degrees with the piston making the suction stroke.

Efficiency Depends on Many Considerations

Editor The Automobile:

[2,349]—Will you kindly advise me through the columns of The Automobile whether or not the efficiency of a gasoline engine decreases as the number of cylinders increase. That is, will a six-cylinder engine, of the same rated horsepower as a four-cylinder, consume more gasoline per minute while turning over at the same rate of speed and developing the same horsepower, all conditions being equal? C. M. Cole.

Berkeley, Cal.

Referring to the thermal efficiency, it has been found that the 6-cylinder motor, when well designed, is capable of delivering nearly 20 per cent. of the fuel value in useful work. This high thermal efficiency has never been exceeded by a motor with a lesser number of cylinders, but there are quite a number of tests available which show a close approximation to this with 4 cylinders. This statement is limited, of course, to automobile motors of the 4-cycle type. The gasoline consumption is reflected by the thermal efficiency. It is true that poor carbureters perform badly, particularly if the number of cylinders is increased, and to some extent this situation has given the 6-cylinder motor a reputation for "drinking" gasoline.

Wants to Become Driver of a Racing Car

Editor The Automobile:

[2,350]—Will you kindly answer the following question in your "Letters Interesting." For nearly four years I have tried to become a driver of a racing car, in either a track or road race. I have had five years' experience and have driven a car on a mile track for 1 mile in 4 seconds slower than the records. Can you advise me how to secure a position as a racing driver?

New York City. C. B. M.

Grow a reputation sufficient to attract owners of racing cars. One way is to get permission to become attached to a racing team and "fag" for it without compensation until you attract notice. Another way is to buy a big racing car and enter it on the provincial circuits. This formula is a little bit high-priced.

Radiator May Be of Insufficient Capacity

Editor The Automobile:

[2,351]—I am a subscriber to The Automobile and wish you would answer the following question: I have a 1910 car and every time I use same I have to fill the radiator with water. The motor gets very warm and forces the water up and out of the overflow pipe. It makes no difference how much water I put in the radiator it will invariably empty itself down to below the top of the tubes within three miles running. Is this doing any harm to the motor, or is it natural for some cars to act in this manner? Air must get into the bottom of the radiator and lift the water up to the overflow pipe. Is there any remedy for it? I have heard that it is only a natural condition with the car, but I would like to satisfy myself thoroughly about it.

Harrisburg, Pa. R. H. Senseman.

If the motor is in good working order, that is to say, clean and is operated on an advanced spark, your trouble may be traced to an insufficient cooling system, unless perchance the circulating pump is in a leaky condition. If the motor is quite old, it is possible that incrustation is responsible for the boiling away of the water. It will be understood that the water, after it absorbs heat from the cylinder walls, must have this heat absorbed from it in turn, or the temperature of the water will increase to the boiling point. If incrustation is responsible for the trouble noted, it will be an extremely difficult trouble to overcome. It is quite impossible to be able to get at the incrusted surfaces in the radiator for the purpose of scraping the crust off, and unfortunately it will not come off by a dissolving process through the use of any chemical that will be safe to employ for the purpose. It is just possible that you have the habit of running on a retarded spark. If so, no radiator will suffice for the purpose, and the remedy lies in learning how to operate your motor properly. There is just one other point that may be responsible for your difficulty. Hot water occupies more space than when the water is cold, and you may fill the radiator to the brim, in which case after the water is heated the excess will spill out.

The Pyrometer

ITS DEVELOPMENT AND USE. BEING THE SECOND INSTALLMENT OF AN ARTICLE BY WM. H. BRISTOL READ BEFORE THE SOCIETY OF AUTOMOBILE ENGINEERS AT ITS SUMMER MEETING.

THE platinum-rhodium couple instrument which has been described may be classed as a high-resistance pyrometer in comparison with the pyrometer using a base metal thermo-electric couple.

Base metal alloys have been found as the result of many experiments which produce high electromotive forces with practically uniform increase of the same in proportion to the increase of the temperature, and which have high fusing points, and produce a uniform electromotive force after continuous use, thus meeting the commercial requirements very satisfactorily.

In practice in the treatment of steels the ranges of temperature required are mostly below eleven hundred degrees Centigrade. For this maximum range special thermo-electric couples have been selected, the thermo-electric force obtained from this couple being several times greater than that of the platinum-rhodium couple, making it possible to use an indicating instrument with jewel bearings in place of the delicate suspension galvanometer.

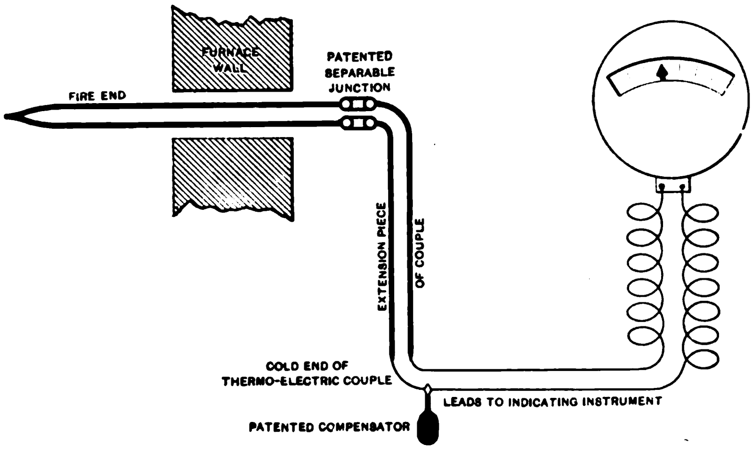

Fig. 2—Fire end of thermocouple applied horizontally through side of furnace

Couples formed of base metal alloys have also been developed for ranges above two thousand degrees Fahrenheit, but they are not capable of withstanding continuously these temperatures.

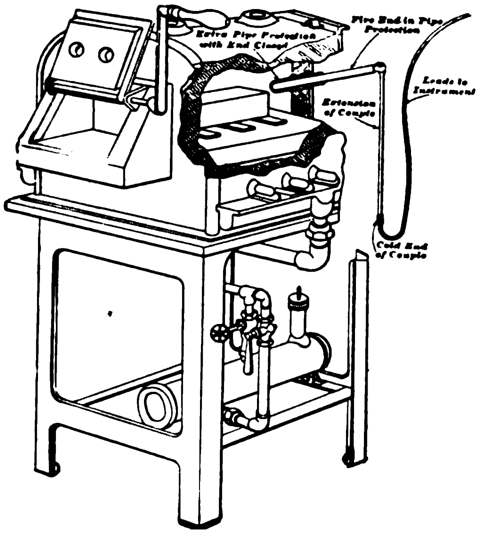

Fig. 3—Showing manner of applying fire end, with extension piece, to furnace

For convenience in comparing the extra power developed by the base metal couple with that of the platinum-rhodium couple, the table No. 2 gives the electromotive forces for the different temperatures up to 1100 deg. Cent., the figures in this table being obtained from a standard Bristol's pyrometer couple taking an average test. The upper line in the diagram No. 1 shows the curve obtained from plotting the temperatures and millivolts. It will be seen that the line is nearly straight. If the indicating arm of the pyrometer is set at 75 deg. Fahr., the average room temperature, no corrections will need to be made for the cold end, provided it is placed where the temperature is maintained at the average room temperature.

Room Temperature.—As no rare metals are used in the low resistance type of couples it is possible to employ elements of large cross-section which will not be affected in their resistance to any appreciable amount by the variation in temperature along the lengths of the elements forming the couple. It is, therefore, also practicable, in commercial service, to have the thermo-electric couple made of sufficient length to carry the cold end beyond the influence of the radiation of heat from the furnace and conduction along the thermo couple and its protecting tubes.

In practice where the thermo couple is thus extended a novel feature is that of separating the thermocouple into two parts, one which is called the fire end, and the other the extension piece, these parts being joined together as near as practicable to the point where the thermocouple passes through the wall of the furnace in which the temperature is to be measured.

The diagram No. 2 illustrates the fire end applied horizontally through the side of a furnace with the separable junction and the extension piece extending vertically toward the floor with the leads connecting to the indicating instrument.

The advantages of the separable junction will be obvious, as it makes it possible to renew the fire end of the couple whenever it is necessary, with the minimum amount of expense, and secondly it permits carrying the cold end to a point toward the floor where the atmospheric temperature will be practically uniform, and away from the influence of the temperature which is being measured.

Fig. No. 3 shows the manner of applying the fire end with the extension piece to an "American" gas furnace.

Diagram No. 4 shows a bent fire end applied to a metal bath with the separable junction and extension piece located vertically with the cold end near the floor away from the influence of the furnace.

Fig. No. 5 shows a method of applying the fire ends of thermocouples to Brown & Sharpe hardening and annealing furnaces and illustrates the separable junction and extension piece made extra long reaching over the side of the furnace and extending to the floor level away from the influence of the heat of the furnace. In the diagrams above referred to showing the application of the fire end it will be observed that a double pipe protection is represented.

The low resistance type of pyrometers are manufactured in

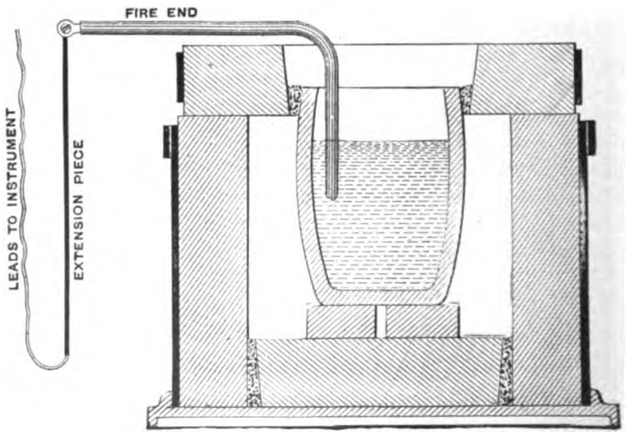

Fig. 4—Bent fire end applied to metal bath, with cold end removed from influence of furnace

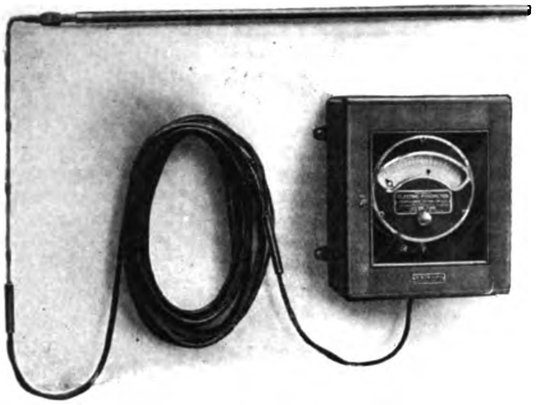

Fig. 6—Low resistance type of pyrometer with separable junction and extension piece vertical

both the indicating and the recording forms, the movements in both instances being of the pivoted type with jewel bearings, as manufactured by the Weston Electrical Instrument Company.

The leads can be made of almost any desired length so that the indicating instrument can be placed at the most convenient point for the observation of the operating attendant.

The low resistance type of instrument is illustrated in Fig. 6, which shows the fire end in a horizontal position with the separable junction and the extension piece vertical.

The details of the construction of the separable joint are shown in Figs. 7 and 8. The separable junctions joining the fire ends and the extension pieces in these illustrations are made with large bearing surfaces with double screw connections to prevent any possibility of variation of resistance at the junction, and, as will be seen by the illustrations, they are so constructed that it is impossible to incorrectly make the connection between the fire end and the extension piece.

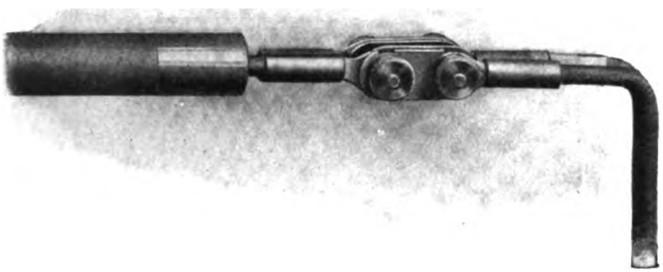

Fig. 7—The separable joint connected up, ready for use

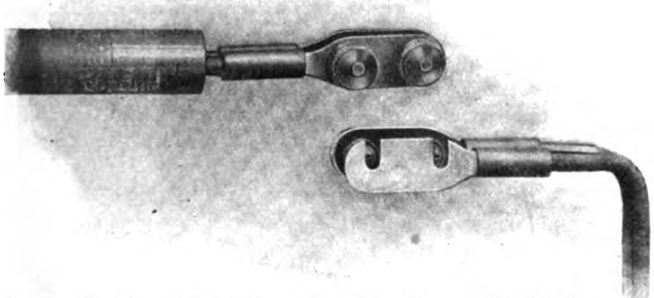

Fig. 8—Showing details of construction of separable joint

The elements forming the couple and the extension piece are independently insulated in an effective manner by winding each with asbestos cord and coating the surfaces with carborundum paint, using a solution of silicate of soda as a binder. This manner of insulation has proven very effective, especially where the fire ends are placed in iron protecting pipes with closed ends and are not moved about when they are in a heated condition.

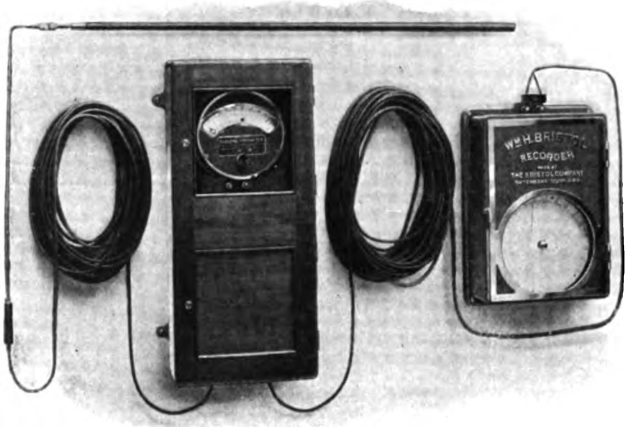

Fig. 9—Complete thermocouple outfit, with indicating instrument connected to single fire end and extension piece

Where the fire ends are applied to furnaces for continuous service a double pipe protection is generally used which can be readily renewed, thus increasing the life of the fire end.

These base metal thermocouples are comparatively inexpensive, making it practicable for a user to keep extra fire ends in reserve for checking and renewing fire ends which have been in long service.

A complete outfit showing the combination of an indicating and a recording instrument connecting to a single fire end and extension piece is illustrated in Fig. 9. This illustration shows the combination unit outfit with the fire end, extension piece and leads to indicating instrument which can be located for the observation of the operator, and also shows the leads connecting to the recording instrument, which can be placed in the superintendent's office, making it possible for the manager of a plant to have before him a continuous record of the temperatures that are being carried at any point in the works. This is a matter of far greater importance than is ordinarily supposed, and the engineer of experience will fully appreciate the innovation and the saving it makes.

(To be continued)

Motor Valves

ABSTRACTS FROM A SECOND INSTALLMENT OF PAPER BY EUGENE P. BATZELL READ AT SUMMER MEETING OF SOCIETY OF AUTOMOBILE ENGINEERS DEALING WITH SLIDE, ROTARY, AND PISTON VS. POPPET VALVES

By assuming that the gas velocity remains 50 feet per second during the whole period, the inlet valve remains open after the crank has passed the lower dead center, and by further assuming a mean figure of valve opening area for this time, we can determine the maximum quantity of fresh charge which can be forced into the cylinder by gas inertia if no losses take place.

Mean valve port area for cams 1 and 2 = 0.45 square inch.

Mean valve port area for cam 3 = 0.62 square inch.

Duration of 45 degrees crank movement at 1000 revolutions per minute = 0.0075 second.

(1) Quantity of gases $50 \times 12 \times 0.45 \times 0.0075 = 2$ cubic inches.

(2) Quantity of gases $50 \times 12 \times 0.62 \times 0.0075 = 2.8$ cubic inches.

"The piston displacement being 117.8 cubic inches, these quantities constitute 1.7 per cent. and 2.38 per cent. of the piston displacement volume. These figures are the maximum possible, and they show that a late closing of the inlet valve cannot have any direct influence on the motor power. Only if the motor were choked strongly at high speed with partly closed throttle or by smaller valves so that there would be considerable vacuum in the cylinder, would the supplementary cylinder filling through late inlet closing be of direct value. The main reason for a late inlet closing is that the cam becomes of fuller shape, affecting the valve port area in such a way that the intake gas velocity is kept lower during the piston suction stroke and the quantity of fresh charge then drawn in is increased. This influence of late inlet closing on the motor power is thus indirect.

"To obtain an air velocity of 170 feet per second, without considering losses, a difference in pressure of approximately 0.25 pound per square inch is required. The difference in pressure required for an air flow (if this difference is not very great) may be found from the equation:

$$P = \frac{V^2 \times Q}{2g \times 144} \text{ pounds per square inch.}$$

where V = air velocity in feet per second, Q = weight of 1 cubic foot of air (about 0.081 pound), and g = gravity acceleration = 32.16 feet. A flow of 50 feet per second requires only about one-twelfth the pressure difference from a flow of 170 feet per second. From this it is seen that without extra resistance the vacuum inside the cylinder necessary or the gas flow is very small, but owing to the existing resistance it may amount to some pounds per square inch in motors only slightly throttled. Therefore, the curve of actual gas velocities through the valve ports differs greatly from the theoretical one, especially at the beginning of the valve opening. This actual velocity will follow approximately curve v, Fig. 2, the shape of which is merely a rational guess. At the 170 degrees crank position this curve v shows no marked difference from curves v_1, v_2 and v_3, and there may be seen also the little direct influence of late inlet closing.

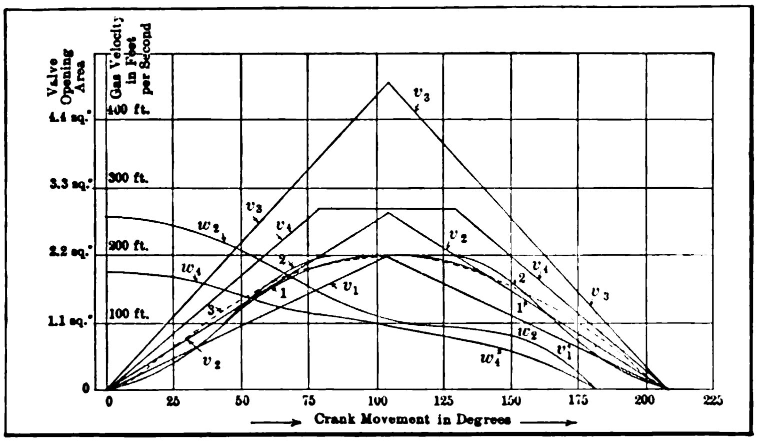

Fig. 4—Valve-opening diagrams

"From the gas velocity curves it may also be deduced that it is more important, from the standpoint of motor power, to have a quick opening inlet of small size than a slower opening inlet of large size. And it is also better to obtain a certain valve port area through large valve diameter and small lift, than small diameter and high lift. The cams for high and small lift being made of the same type, say for instance both after Fig. 1, No. 1, will have coinciding valve opening curves on the length of their straight flanks. The valve with smaller lift, but with a larger diameter, will also have a larger port area during this time and this will help to reduce the high intake gas velocity at the inlet beginning. The influence of a change in the time of valve opening is noticeable by comparing curves v_3 and v_4 of Fig. 2. Curve v_4 corresponds to cam 3 with the valve opening starting at "0" degree crank position. It represents a much lower and also much more constant gas velocity at the beginning than curve v_3; and, besides, these curves practically coincide further along. It follows that, theoretically, an early inlet opening is advantageous, and this statement is true for high speed. In practice, however, better results are sometimes obtained with somewhat later inlet openings, but if a certain long duration of inlet opening is desired, it is better to start and close early, because a too late inlet closing will result in motor power loss. The inlet valves should close before the moment when the piston in its backward stroke compresses the charge inside the cylinder to the pressure in the intake pipe. With a fairly opened throttle, and at normal speed, the cylinder at the end of the suction stroke will hardly contain more than 80-85 per cent. of a full charge. Also the amount of supplementary cylinder filling is very small under the conditions cited, and, therefore, there is no likelihood of a return flow until after about 10 per cent. of the return stroke, or nearly 45 degrees of crank movement. A lag of 30-40 degrees in the closing of the inlet valve is, therefore, not harmful in this respect. However, when the throttle is nearly closed, the pressure inside of the intake pipe will not differ much from that inside the cylinder, and then the piston in making 10 per cent. of its return stroke while the inlet valve is open will cause a part of the cylinder charge to be expelled into the inlet pipe. This results in loss of power and efficiency.

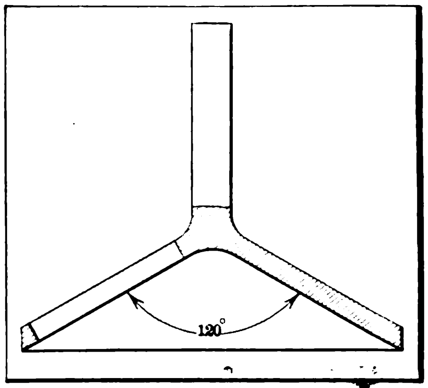

Fig. 3—Conical rotary valve

"If the compression space is 25 per cent. of the total cylinder volume, and the compression starts at 10 per cent. of the return stroke, the effect will be the same as if the compression space were 27 per cent.; but with a compression beginning at 2-3 per cent. of the return stroke, corresponding to a lag in inlet closing of 20-25 degrees, the rated compression of 25 per cent. may be figured on. Other conditions being equal, these compression ratios will result in the following compression and explosion pressures, and theoretical efficiencies:

		Explosion Pressure	Thermal Efficiency Per Cent.
Compression pressure $P_{25} = \frac{v^1}{v}^{1.35} \times 13 = 84.5$ pounds square in absolute		300	39
Compression pressure $P_{27} =$ pounds square inch absolute	76.	270	37.5
Difference	= 8.5	30	1.5

"Having thus discussed the phenomena of the inlet with poppet valves, we could now take up the exhaust in the same way. However, the determination of exhaust gas velocity is a very complicated problem. As long as the pressure inside the cylinder is higher than the pressure in the exhaust pipe we have a flow of gases through an orifice under a pressure difference. This flow depends on the physical properties of the gases, their temperatures, etc. Moreover, the flow occurs under variable pressure differences. It would, of course, be possible to construct a theoretical curve of gas velocity, but it is such a complicated matter that the results would hardly justify the attempt. Being already familiar with inlet valve opening diagrams, and assuming that exhaust valve diagrams closely resemble them, some interesting conclusions can be drawn. The exhaust velocity curve and also the curve of the pressure inside the exhaust pipe is most likely undulatory, with waves of great amplitude at the beginning, quickly decreasing. A sudden escape of gases is followed by a heavy drop in pressure inside the cylinder, which may become lower than atmospheric. This vacuum is then filled in by the outside pressure, with a certain excess pressure due to gas inertia; again the gases expand, and so forth.

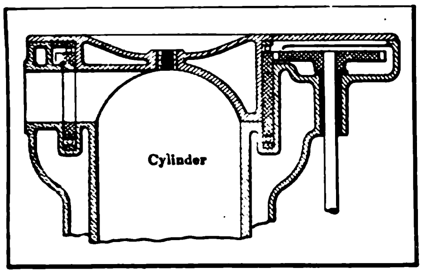

Fig. 5—Revolving sleeve valves outside cylinder

"In the case of gradually opening valves the exhaust has to begin at some point before the piston reaches its lower dead center, otherwise there would be considerable back pressure on the piston during the early part of the exhaust stroke, and consequently loss of power, the latter greater than that due to a reasonably early exhaust opening. If the exhaust begins to open early it may be more lingering. The pressure inside the cylinder at the lower dead center should be practically equal to that in the exhaust pipe.

"The exhaust gas velocity can be depicted approximately by noting the character of the inlet valve opening and supposing it to be shifted over to the right 20 or 30 degrees. An exhaust cam for 40 degrees lead and 5 degrees lag gives the maximum opening at 72 1-2 degrees after the lower dead center, or about 25 degrees before the maximum piston speed is attained. The gas velocity curve will, therefore, slowly rise from 0 degree to 72 1-2 degrees; then rise at a quicker rate to a point of maximum piston speed and gradually drop from this point to zero at the upper dead center. The smaller the gas velocity during this period the less resistance there will be on the piston. An exhaust valve giving a large, quick opening will be favorable not only in this respect but will allow also of a later exhaust beginning. The motor power can be increased by using large exhaust valves as well as large inlet valves.

"It is advisable in many cases to close the exhaust valve after the piston reaches its upper dead center, and particularly so if the exhaust valve closes gradually. At high speed there is considerable back pressure at the end of the piston stroke, and if the exhaust were closed exactly at 0 degree, the pressure line would follow an expanding curve during the piston travel and the admission of fresh charge would begin only at the end of the travel." The author went on to say: "From what has been said it can be seen that quick closing of the exhaust is preferable, with respect to the back pressure."

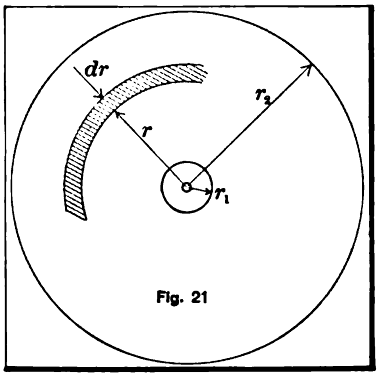

Fig. 6—Diagram indicating power required for rotary valves

As an illustration of a type of rotary valve that might be a possibility in automobile work, the old "Raymond" valve motion was referred to, and some of its qualifications from a theoretical point of view were discussed. The author failed, however, to take cognizance of the fact that the better part of a million dollars was dissipated upwards of twenty years ago to make this type of valve popular, but the project failed. As a matter of record, a 4-cylinder, 4-cycle automobile type of motor, with a bore of 12 inches and square delivered barely 50 horsepower. There were some hundreds of these motors built and the testing facilities available at the time were adequate, so that failure was largely due to the poor results obtained by this plan. It will be remembered that the smaller sizes of motors performed fairly well, but there were times when the flat rotary valve rubbing against the flat dome of the cylinder gave lubricating trouble which could only be cured in a percentage of the cases. This type of valve was modified and reproduced in THE AUTOMOBILE possibly a year and a half ago, and as was suggested at the time, the conical shape afforded larger port areas, and should perform somewhat better, as Mr. Batzell states: "A conical angle of 120 degrees (combined) affords a port area of 15 per cent. over that of the flat valve in the case taken." The conical valve of the rotary type referred to is shown in Fig. 3.

In relation to constant gas flow through rotary valves, the author plotted curves as shown in Fig. 4, stating: "The maximum valve opening is not important by itself, as the time factor also enters into the problem. In rotary valves driven at a constant speed, and with ports shaped to give the maximum possible opening area, the area of opening at any moment is proportional to the angle through which the valve has turned. The area of opening increases uniformly from the beginning of the opening until the maximum is obtained and then decreases in the same manner. The curve representing the change of this area with reference to the crank movement will be an equilateral triangle. The curve for the Raymond type of valve is given as v_1 in Fig. 4, and for the sake of comparison the curves of the

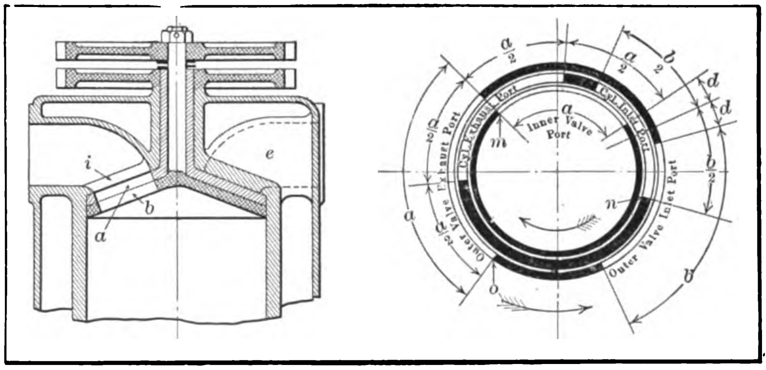

Fig. 7—Double rotary valve. Fig 8—Position at time of exhaust closing of Fig. 7 valve. Motion transferred to cylindrical for clearer understanding

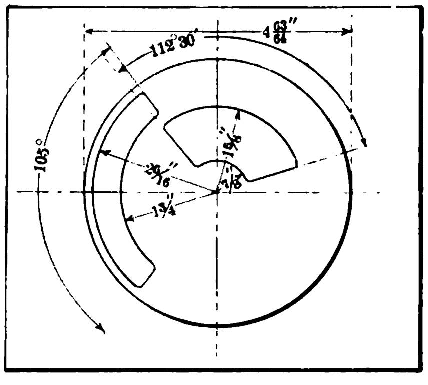

Fig. 9—Another double rotary valve construction

cams as depicted in Fig. 1 (first installment) are reproduced in Fig. 4, but all openings start at 0 degrees of crank position. (In this article the cylinders are supposed to be in the same plane as the crankshaft—not offset). It will be seen that the curve v_1 has a much smaller enclosed area than curves 1, 2, and 3. Moreover, the valve opens and closes but a trifle quicker than with cams 1, and 2; Fig. 1, and less quickly than with cam 3. The theoretical curve of gas velocity will not be as good with this type of rotary valve as with poppet valves, but the actual condition of the gas flow may be better. In poppet valves, the gas flow into the cylinder through a comparatively narrow opening offers considerable resistance. Besides, a part of this annular opening is close to the walls of the explosion chamber unless the valve is located in the center of the cylinder head, and that tends to change the flow through the valve. The paths of unequal length which the gas particles passing through the different section of the valve opening must travel further diminish the value of the poppet valve port effective area. The rotary valve, on the contrary, will allow a practically constant flow through its total area, and with small loss.

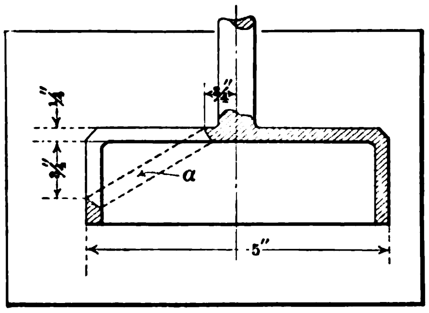

Fig. 10—Cap form of rotary valve

"The flat disc valve can be improved in respect to cylinder filling, if it can be made larger." The author points out that by having separable cylinder heads, the flat valve can be made of larger diameter than the bore of the cylinder.

Referring to the question of the power required to drive rotary valves, the author states: "The rotary sleeve, if properly made and lubricated, may consume very little power, particularly systems like Fig. 5 in which the valves are not exposed to the explosion force or to the side pressure of the piston on the other side. Systems with disc or cap valves are subjected to friction, caused by the full force of the explosion which might aid one to believe that a great amount of power is required for their driving.

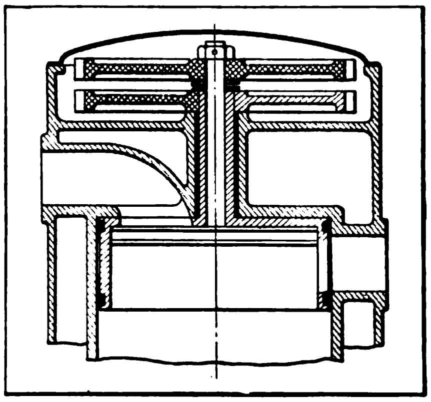

Fig. 11—Modification of cap valve shown in Fig. 10

Assuming pressure of valve against seat has a mean value of t, Fig. 6, the power necessary to overcome the frictional resistance of an elementary band of radius r and of width dr is:

$$p \times f \times 2\pi \times r \times dr \times \frac{\text{R. P. M.}}{2} \times 2\pi \times r,$$

Where f is the coefficient of friction R. P. M. are expressions in motor revolutions for a halftime valve." The author continues with the arithmetical expressions integrating between limits, r_1 and r_2, simplifying and substituting, finally arriving at the conclusion that the motor taken when developing 10 horsepower on the brake at 1,000 revolutions per minute with a mechanical efficiency of 83 per cent. with a valve friction of 0.1 consumes 0.525 horsepower in operating the valve.

Fig. 7 shows a double rotary valve. Fig. 8 is a diagram of the same, and Fig. 9 is another double rotary valve construction. In considering the power required to drive these types of valves, Fig. 7 works out on a 1.15 horsepower basis.

Fig. 10 shows a cap form of rotary valve, and Fig. 11 is a modification of this cap form of valve.

(To be continued.)

Digest

BRIEF RÉSUMÉ FROM 50 FOREIGN PAPERS; HANDLING 2-CYCLE LION-PEUGEOT MOTOR; LOUIS RENAULT MOTOR; PRODUCTION OF VALVELESS 4-CYCLE MOTORS; HIGH-VOLTAGE STORAGE BATTERIES, AND ADVANCES IN AVIATION

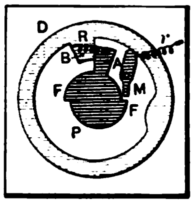

Fig. 3—Diagram of device for starting ignition with magneto in Lion-Peugeot two-cylinder V-motor

A partial description is offered of the two-cylinder Lion-Peugeot automobile motor, which is a close kin to the motorcycle of the same make, though with enlarged dimensions, and of the single cylinder, long stroke motor which was favorably noted at the recent racing meet and hill climb at Boulogne. The two cylinders are placed at a V of only 20°, and are cast in one block integral with their water jackets and with a valve-enclosing chamber. The latter is accessible through a gate at the top which may be removed by loosening a single screw. Particularly in the motocycle type of motor this arrangement serves to obviate spattering of oil from the valves and to reduce noise. A bevel gear *J* on the motor shaft *Y* drives the shaft *N* which in turn drives the camshaft *F* by spur wheels, and the cams *SS* for the exhaust and *TT* for the admission actuate the bell cranks *A* on the shaft *U*, the latter being adjustable longitudinally, as indicated in one of the accompanying illustrations, so as to reduce the compression for starting in the well-known manner by keeping the intake valve open longer than normally. The magneto and the pump are mounted on a shaft parallel with the camshaft and are rotated from the latter by means of straight spurwheels of equal size, so as to turn at the same speed. One of the connecting rods embraces the whole width of the crankpin *H* between the two internal flywheels WW, and the other connecting-rod knuckle is a simple steel ring bearing on the outside of the first one as at *hhh* in the second illustration, the relative motion of one rod to the other being so slight that only small bearing surface is required. *G* represents the inlet for lubricating oil. *L* is an end thrust ball bearing. A locking arrangement for securing and adjusting the valve springs is indicated at *d*. In order to produce ignition by the magneto *M*, without resorting to variable advance of the spark, there is mounted upon the shaft of the magneto a disk *P* which carries a lug *A* which is normally pressed strongly against another lug *B* forming part of the actuating pinion *D* (driven from the camshaft). But the disk *P* may be stopped in its rotation by a pawl *M*, controlled by the driver. In that case the pinion *D* continues to turn and lugs *A* and *B* separate, but the spring *R* tends to draw them violently together. At the moment chosen for ignition a cam fixed upon pinion *D* releases the pawl *M* and the disk *P* is then very much accelerated, until the two lugs are again in contact, but meanwhile the rupture has been produced in the magneto with great force, because the moment when the pawl released the tooth *F*, the lug *B* had already passed the position corresponding to that set for normal ignition. This device is only used for starting and when it is desired to get the advantage of fully advanced ignition. For normal travel, the magneto is permitted to cause ignition for one of the cylinders 10° ahead of the position which would be chosen for a motor with vertical cylinders, and for the other cylinder 10° behind time. But the explosions in this motor must of course take place at intervals of alternately 380° and 340°. It is made with either 75 mm. bore and 150 mm. stroke or with 85 mm. bore and 150 mm. stroke, giving respectively 12 and 16 hp. according to the rating, but in reality much more.—*La Vie Automobile*, July 2.

Drawings reproduced from a patent recently secured by Louis Renault show a cylinder *a* flared conically at the top and a valve sleeve *b* concentric with the cylinder and similarly shaped. The conical part of the sleeve is provided with four ports adapted to cover and uncover successively the induction and exhaust openings *A* and *E* in the cylinder. The sleeve in whose cylindrical portion the piston *c* travels is rotated around its axis by means of a spiral gear *e* near its bottom driven by a worm *d*, and its speed of rotation is one-eighth of that of the crankshaft. The ports 1, 2, 3 and 4 of the sleeve are spaced 90° apart (measuring on the plan projection instead of on the cone), while the induction and exhaust ports in the cylinder are offset suitably to admit of advancing the exhaust and retarding the closure of the induction. Suppose the intake opens 10° past the upper dead center and closes 25° past the lower dead center and that the exhaust opens 40° past the lower dead center and closes 5° past the upper dead center. The manner in which the mechanism will function may now be realized. The intake is open for the space of 195° and the exhaust for 225°. The compression and the explosion or expansion, during which phases of the cycle all openings must be closed, comprise 295°, and between the closing of the exhaust and the opening of the intake everything is closed for 5°. These four divisions of the full cycle of 720° must be represented on the sleeve in the space of 90°, since the sleeve turns once for eight revolutions of the crankshaft and consequently one-fourth of a revolution for the two revolutions representing a full cycle. The angle *A* representing the intake on the sleeve must then be one-eighth of 195° or 24° 22′ 30″. The angle of compression and explosion, *C* + *D*, must similarly be 295° divided by 8, or 36° 52′ 30″ and the angle of the exhaust *E* must be 28° 7′ 30″, and finally the small angle of closure between exhaust and induction must be 37′ 30″. If the ports are limited by two *radii vectores* of the cone which in plan projection are 12° apart, for example, it will be necessary to give to the opening *A* in the cylinder a width of 24° 22′ 30″ minus 12° = 12° 22′ 30″ and to the opening *E* similarly 16° 7′ 30″, and the size of the openings may be made as great as necessary by enlarging them as well as the sleeve ports radially. The exact positions of the cylinder ports are readily determined. Under the suppositions of timing assumed above, the motor functions for 715° between the moment when induction begins and the exact moment when the exhaust closes. If port 1 has uncovered the admission it is port 2 which must uncover the exhaust in the same cycle, since no other port of the sleeve can pass the exhaust opening meanwhile. The opening edges of cylinder ports *A* and *E* must therefore be a certain distance apart corresponding to the sum of 90°, which is the distance from port 1 to port 2, and 61° 15′, being one-eighth of 490°, which under the suppositions given is the distance between the beginning of the induction and the beginning of the exhaust. This places the two opening edges 151° 15′ apart, and under different assumptions with regard to the proper moments for opening and closing of the ports this would be varied accordingly, of course.

The upper part of the sleeve, it is noticed in the illustration, is provided with three grooves in which are lodged tightening rings *f* to prevent the escape of gas from or to the cylinder. In his patent Renault also secures a sleeve in which there are only two ports, in which case the sleeve will be required to rotate at one-fourth the speed of the motor. The author comments upon the advantages of the construction in securing an unimpeded path for the gases, its robustness and simplicity, and he holds that, if the ports seem small, they may be easily enlarged by lengthening the cone and reducing its angle.—F. Carlés in *La Vie Automobile*, July 23.

Only large manufacturers can see their way to go into the production of valveless four-cycle motors and this fact is becoming an additional reason for large manufacturers to go into it, apart from the merits of the type, everything being welcome which promises distinction from the small producer and doubly welcome if it is plainly in the line of mechanical progress. The difficulties of adequate production, involving high accuracy, superior materials and the possession of an elaborate equipment of intricate machine tools, become a recommendation when the eventual results are assured. Something of this view, tempered with consideration for the large majority of the members of the industry who are not prepared to make all the changes and submit to all the expenses involved in the discarding of the poppet valve, is leaking out in the European press in many devious ways and expressions scattered throughout many paragraphs and articles. The success accomplished with the Knight motor by the British Daimler company and by the Minerva company of Antwerp, Belgium, their invasion of the French market, the readiness of the Panhard-et-Levassor firm to turn out their first chassis with valveless Knight motor, this fall, and trials which show 42 hp. for a valveless motor of dimensions which could not be made to yield more than 35 hp. with the older system and the same fuel consumption, constitute facts which divide the automobile industry of Europe in two camps, one consisting mainly of the large manufacturers, who look forward to the valveless motor in some form, as a savior of distinction and price, and another comprising a much larger number in all classes who work feverishly to perfect the motor with extraordinary length of stroke or the two-cycle motor or one of the types of motor which have sprung into existence through

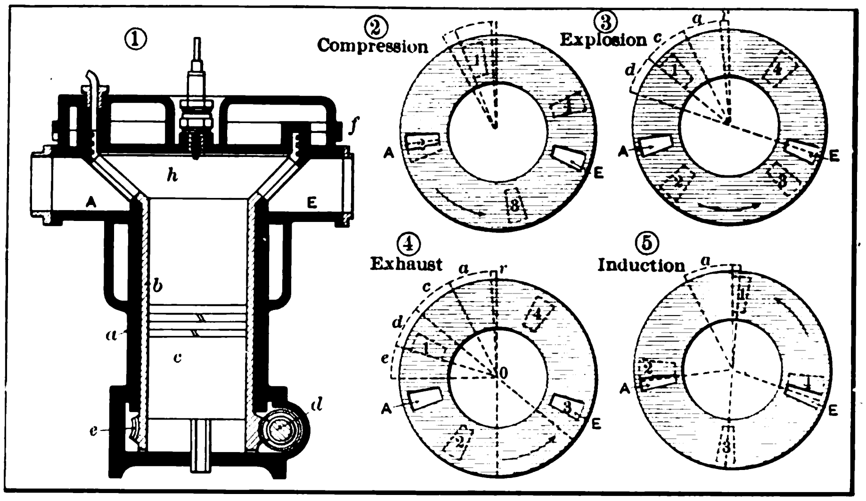

Fig. 4—Reproduction of patent drawing for Renault valveless motor. (1) Sectional view of cylinder. (2) Plan view showing position of ports at end of suction stroke. (3) When port 1 has passed the angle c, representing the compression period, the explosion will take place. (4) Exhaust to begin. (5) Suction to begin.

the demands of aviators and promise suitability for automobiles. Among the large number of articles whose gist is given in the foregoing remarks one deals with the patents secured by Louis Renault for a valveless motor of a special type, but it is notable that the Renault firm does not yet authorize any statement to the effect that this type will be manufactured or has been found satisfactory. The fact remains that the trend is in the direction of lighter motors and the chances are that the activities of the present will lead to certain improvement before the end of the chapter.

Ordinary electric storage batteries give but small voltage, ranging from 1.8 to 2.4 volts, and the iron-nickel batteries even less, so that it is necessary to place a large number of elements in series in order to obtain high tension. But now a high-tension element has been invented by Mr. Gross, a teacher of music at Christiania, Norway. *Elektrophysikalischer Rundschau* publishes curves representing the discharge of the first Gross element and of a subsequent improved type. The first element weighed 1-2 kilo, and was discharged at the rate of one ampere. The initial tension was 55 volts, but at the end of ten minutes this had fallen to 24 volts, after 20 minutes to 16 volts, after 30 minutes to 12 volts, after 40 minutes to 10 volts, and finally, after one hour, to 8 volts. The construction was therefore not practical. But the improved type gave better results. It weighed 2 kg., and was in the form of a cube 140 mm. (7 1-3 inches) high. The initial tension was reduced to 26 volts, but at the end of two hours of discharge the voltage was still 23. This element yielded 20 watt-hours per kilogram, being in this respect inferior to lead-lead batteries, as used in public cabs, which yield 35 watt-hours. Later information indicates that further improvements of the Gross battery have been effected, especially that the output is now superior to that of older types, while the voltage remains considerably higher. A rapid discharge battery, convenient for experimental work, may thus soon be available.—*L'Automobile,* June 25.

A remarkable flight with a monoplane which has not been recorded in the aeronautic journals took place on Saturday, June 25, last. The Belgian aviator, Gaston Goffaux, rose with the "Belgica," a monoplane of his own design, at St. Job, near Brussels, while the wind blew at the rate of from 15 to 22 meters per second (which equals a mile in 80 seconds, maximum). Terrible gusts swept the field. During the first trial, which lasted 25 minutes, the monoplane maneuvered peaceably at a height of 100 meters, without apparently being in the least disturbed by the unceasing onslaughts of the angry atmosphere. Accordingly as the aviator headed the wind or went with it, his speed diminished till it seemed the machine hung motionless in the air or, on the contrary, burst into a dizzy velocity. But its stability asserted itself so remarkably that two spectators did not hesitate to join the pilot in a second experience. One of these new passengers weighed 85, the other 100 kilos. Mr. Gaston Goffaux promenaded them around in the tempest for ten minutes at a height of 50 meters, cut out his ignition several times and took them back to the ground in gliding flight. The monoplane in question has flexible wings, and here lies, it seems, the whole secret of its tranquil resistance to the violent air currents. Its inventor has decided to fly from Ostende to London, in the first days of August. "I don't believe," adds the writer, "that I have ever written you anything which equals in importance this dry and astounding report of one flight among a thousand."—Henry Kistenmaeckers, in *La Vie Automobile,* July 16.

The thrust of an atmospheric screw propeller, whether constructed with true helical pressure surface or with the preferable curvature of 1-14 or any other curvature, is always the same for the same torque of the shaft, and tests made with a propeller *in loco* are therefore sufficient to establish its qualities. It is not necessary to undertake costly arrangements for trying it at varying forward speeds, but it is desirable to test motor and propeller together. While the rotary speed of the screw increases with forward speed, the angle of incidence against the air is at the same time reduced, and the thrust remains unchanged.—From calculations by C. Eberhardt in *"Theorie und Berechnung der Luftschrauben."*

Don't

WHEN A PATIENT IS AILING THE DOCTOR DOES NOT APPLY ALL THE REMEDIES KNOWN TO "MATERIA MEDICA" IN ORDER TO MAKE SURE OF HAVING APPLIED THE RIGHT ONE. A PROPER DIAGNOSIS IS OF THE FIRST IMPORTANCE—SO WITH AN AUTOMOBILE.

Don't be selfish; if you have had trouble with your car and the remedy you applied proved to be efficacious, be generous; take the time to tell your brother autoist how it was accomplished. THE AUTOMOBILE will furnish the means of transmission. Write to the Editor—on one side of the paper only—setting forth the facts.

Don't imagine that literature is what is wanted in a matter of this sort; facts are most in need; literature can be purchased at a book store for a small sum; facts are as scarce as chicken teeth.

Don't imagine the character of trouble that you experienced is too trivial to tell about; if it gave you a bad half-hour, then, by telling the other fellow, he will be favored.

Don't become superstitious when your motor fails to work. The patent medicine man takes advantage of just this fault in man. It is easy to imagine that one is ailing from every disease under the sun after reading a patent medicine advertisement—it may only be a hankering for a dish of ice cream.

Don't purchase an automobile without considering what it is to be used for; a banker would scarcely want to be taken to his place of business in the morning on a five-ton truck. The trouble that some autoists have is due to having selected the character of automobile that fails to accord with their needs.

Don't part with your money until you find what you want—just the right kind of a car is available somewhere—get it.

Don't forget solid gold hunting cases do not always house good watches. While it is wise to let your wife select the body, it will be a good stroke on your part to examine the works.

Don't purchase real estate without having the property and its title examined. Why go at it blindly when you put an equal amount of money in an automobile?

Don't purchase a pocketbook with your last cent. If you cannot afford a road locomotive, and the cost of maintaining it, buy the kind of automobile that will take you where you want to go every time you have to make the journey, at a cost well within your income—just such automobiles are to be had.

Don't imagine you were skinned if you find that the car you selected is not what you wanted—the salesman is not a fortune-teller.

Don't expect the salesman to drive you away from his door; he is there to sell you his make of car; not the make of his competitors.

Don't expect a runabout to go as fast as a touring car. It is prejudicial to the life of the runabout to force it to trail a touring car. Be content to drive leisurely. The scenery along the roadside is superior to the dust thrown up by the car ahead—fall back.

Don't forget to "sniff" if a salesman paints a cabbage to look like a rose. If he deceives the eyes, rely upon the nose.

Don't drug your good judgment by a "plethora" of extras on a car; what you need is a good automobile; make sure that you have the foundation even if you have to do without the extras. Lamps are used to illuminate the space ahead, not to provide the means for going ahead; the lamps will be of no use if the car is faulty.

Don't make the mistake of stopping at a saloon for gasoline; the kind they keep in such places would burn the lining out of the tank.

Don't keep a chauffeur twenty minutes after you find that you can dance a jig upon his breath. A befogged brain makes a bad steering wheel.

Don't try to overcome the ills of poor springs by running on partially deflated tires. Slow down to the speed where the springs will do the work. The tires will give out too soon if they are not kept inflated.

Don't race with other autoists on the road; you become a criminal by subjecting your automobile to criminal abuse even if you do not maim or kill a citizen.

Don't contest the right-of-way with a locomotive; when you come to a railroad crossing stop (if necessary), look, and listen.

Don't use your muffler cut-out as a means of telling the public that you own an automobile. A better way is to stand on the corner and politely inform the passers-by of the fact; be sure and clearly state the make, model, horsepower, from whom it was purchased, and the cost.

Don't look with disdain upon the fellow who elects to walk; he may be just as able to buy tires as you are.

Don't let "Financial Apaches" get away with the story that you mortgaged your home to purchase an automobile.

Don't be sarcastic. If you are able to afford a more pretentious looking car than your casual acquaintance, what of it? No man ever stole to be poor.

Don't argue with a policeman; if you take umbrage at his nationality, remember that he was not consulted; remember also that it is the law he represents—his duty is to call your attention to the defect which resides in your interpretation of the same.

Don't imagine that the Legislature made a mistake in printing the Law, making it read 30 miles per hour instead of 45 miles per hour—the printed figures are probably right.

Don't mope along the road until you come to a corner and then press the accelerator; it may be exciting to go fast on a curve, but the nights are long in a hospital ward.

Don't put a 20-horsepower horn on a 10-horsepower automobile and deceive yourself into believing that you are doing a mile a minute; remember the public; it, too, has ears and a sense of the fitness of things, even if you have not.

Don't fill your gasoline tank at night with the lamps lighted; were it not for the fact that gasoline is quick burning and energetic, the automobile would not run. The piston in the cylinder of the motor is quicker than you; it manages to get away; you may not succeed.

Don't spill as much gasoline on the ground as you put in the tank; it is not only extravagant, but it is dangerous.

Don't think you can make an automobile go without gasoline; when the motor stops, look in the tank.

Don't reach the conclusion that a full tank is absolute assurance that the gasoline gets to the vitals of the motor; there may be a wad of waste in the piping system—as Maude Adams said, "It 'as been 'erd uv."

Don't reach the conclusion that every cell of the battery is in good order just because you find one cell to be so; test each cell; eliminate the "dead" one and be happy.

Don't neglect the auxiliary ignition system for months just because the magneto is a willing worker; even a giant is likely to catch the "grippe."

Don't press down on the starting crank; a friend of ours is now sporting a broken arm from this cause; 56 per cent. of all accidents are due to this practice. Pull up (smartly) on the starting crank; let the flywheel do the rest.

The Automobile Club of Germantown

AWAY back in the Dark Ages of motoring—in 1901, to be approximate—ten residents of Germantown, Pa., who owned automobiles, experienced a pressing need for a common garage. They were all men of wealth and prominence in business, social and professional life and when the idea took concrete form, they were not long in giving it definite expression. This expression took the shape of renting the old fire house, located on the Germantown road, and in this ancient building the members of the little syndicate housed their cars.

Thus was born the Automobile Club of Germantown, which stands unique among the automobile clubs of the United States in several particulars.

The cars owned by this little group of motorists would make a strange appearance to-day lined up in Fairmount Park or along Riverside Drive. There were expensive foreign automobiles among them, one in particular having wheels almost as high as those of a buggy; there were curious, asthmatic steam cars of types long dead; racing machines of very moderate speed as judged by the standards of to-day and generally the cars bore characteristics that have been eliminated in present construction.

In order to show how fast has been the development of the automobile since 1901, the fact may be cited that one of the first runs of the club was to Trenton, N. J., and return, a distance of about 50 miles. This was accomplished within twenty-four hours by most of the members. To-day the same run could be made in three hours, without doing anything unlawful or out of the ordinary.

But in that day the "big" tour of the Germantown motorists caused quite a little stir and really marked a step in demonstrating the utility of the automobile.

But the club was not born full-grown. It was at least two years after the period in which the fire house was rented as a garage before the members decided to add a club feature to their project. Letters to leading enthusiasts were sent by the originators of the idea and almost immediately flattering results became apparent. They were invited to ally themselves with the pioneers in an incorporation pledged to build a pretentious clubhouse and formed with the idea of making the pathway of the automobile more pleasant.

Great care was taken in selecting the members and a cast-iron limit was placed upon the membership rolls. While from the very nature of the club money was a secondary object, the financing of the whole project was done with all the skill and finesse known to the world of business. This was possible because the men who formed the club were of the most advanced types of business men and professional men.

The records of the club show that an astonishingly small amount of actual money was necessary to launch the project and from that small beginning the physical assets of the club to-day have increased to more than $60,000.

The first step in the way of progression was the acquisition of a magnificent site for a clubhouse, hard by the Pennsylvania Railroad station at Carpenter. Prescott Adamson was chosen first president of the club, which assumed the chartered name of the Automobile Club of Germantown. In 1904, the original building was completed and the club took possession. It sat upon a little hill and its walls were of rough stone. On the level of the road a cemented garage was built, occupying the whole basement of the clubhouse. The main floor consisted of a veranda running the full length of the structure, ending in a wide, open-air dining room. Inside was the lounging room, kitchen and storage rooms of various kinds and a commodious hall for dancing and social functions. Back of the social hall was a suite of rooms devoted to the ladies. These rooms were delicately and delightfully furnished and fitted with sumptuous elegance. Upstairs were the baths, billiard and pool rooms, directors' room and the living apartments of the chef.

Back of the building the club installed tennis courts of perfect construction.

For several years these quarters and arrangements were adequate, but last year it became apparent that the club would have to have more room. This was supplied by an addition to the clubhouse which has recently been completed at a cost of about $15,000. The addition gives the club one of the finest bowling alleys and billiard rooms, similarly situated, in the country. It enlarges the culinary department, so that the eyes of Jules J. Dirac, the major domo and master of ceremonies, shine when he discusses them. It increases 100 per cent. the garage facilities; doubles the bathing accommodations and brings the clubhouse plant right up to the minute in every convenient way.

The building as it stands to-day is vastly larger than it appears. It is 180 feet deep by 125 feet long, and every detail has been supplied with the idea of accommodating its members.

Mr. Adamson was re-elected to the presidency after his first term and was succeeded in office by Thomas B. Prosser, who served two years. Then Robert P. Hooper was chosen head of the organization and for three years he has conducted the administration of club affairs.

The organization, as noted, has several unique distinctions. Its object, according to its constitution, is "to maintain facilities for the sport of automobiling and other innocent or athletic sports and for the purpose of maintaining a club for social enjoyments and for the development of social intercourse."

From September 15 until after Ash Wednesday the clubhouse is the scene of social activity several times each week. The cuisine has gained a name for itself, and at this time, when a majority of its members are traveling or enjoying recreation abroad or at American summer resorts, the memorandum book of Mons. Dirac contains numerous orders for formal dinners to be given next winter. The ladies take advantage of the facilities offered by the club, and bridge parties, luncheons, dinners and dances are being scheduled now for the coming season.

The Automobile Club of Germantown is the only organization of its kind that has a bona-fide "waiting list," as far as data at hand shows. Applicants whose names have been favorably acted upon by the governors are obliged to wait until a vacancy exists before being received into full membership. As a result, it means something to belong to the club.

While the club is a negligible quantity so far as racing and hill-climbs and contests are concerned, it is a power in other ways. Its roster contains the names of men whose membership spells power and progress. It works through the Pennsylvania Motor Federation in State-wide matters of importance to motordom, but takes small part in the administration of such matters. It is said of the Automobile Club of Germantown that when it comes to the important matter of settling the bills or providing finances for big matters touching close to the heart of the pleasure of motoring, its position is unassailable. When a job of sign posting has been done or when the legislative committee of the State body wishes to push some important legal matter, the Germantown organization always "comes to the front handsomely."

Now as to the details of the club: The garage has space for forty-eight automobiles and there is a waiting list for such space as "long as one's arm." The club goes in for billiard and pool tournaments, tennis matches and tournaments, bowling and various other contests outside of motoring. Its list of honorary members includes the names of the clergymen of Germantown, who frequently take advantage of the club privileges.

Aside from Mr. Hooper, who is president of the club and who says that after the current year, when his term expires, he will retire to a plain membership, the officers of the club are as follows: Vice-President, Clifton H. Wheeler; secretary and treasurer, Stephen B. Ferguson; chairman of the house committee, Dr. Edward F. Kamerly; garage committee, William R. Harper; automobile affairs and entertainment, Clifton H. Wheeler; membership, Stephen B. Ferguson; bowling, W. T. Betts; billiards and pool, Dr. Herbert P. Fisher; tennis, James Poole Hooper, and good roads, Charles H. Thompson.

Robert P. Hooper is also president of the Pennsylvania State Motor Federation and several of the officers of the club are active in its councils.

Coming Events in the Automobile World

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

AMONG communications from autoists, as they come to the Editor from time to time, there are quite a number of the character that indicate more or less dissatisfaction. Some of them speak unkindly of two-speed transmission systems, but we note that they hail from mountainous districts, which rather goes to indicate that the purchasers themselves were lacking in judgment. Every purchaser should know that there is no sense in going to the expense of placing a transmission gear in an automobile if it is not there for a purpose. No automobile should require a transmission gear on a level hard road; the flexibility of the motor should be sufficient to permit of running the car fast or slow at the will of the driver under all hard road conditions.

* * *

WHEN the road becomes soft, or the grade exceeds 1 or 2 per cent., the flexibility of the motor begins to peter out and the necessity of the transmission gear arrives. Just how many speed changes are necessary under bad road conditions depends upon how bad the road is. It would be an error in judgment in all probability to attempt to brave Pike's Peak in a small car fitted with a two-speed planetary gear. Would this be the fault of the planetary gear, or should the difficulty be charged up to Pike's Peak? It is scarcely to be expected that anything would be gained by attaching the blame to either the planetary gear or Pike's Peak, nor can the purchaser evade the consequences.

IF it is an error in judgment to attempt too much with a runabout, the only remaining question is whose judgment is at fault? Common law presents the dictum "Let the buyer beware" (*Caveat Emptor*). Every business man acting in his normal capacity understands this legal situation perfectly. Why should he disregard this basic principle in law when he goes forth to select an automobile for his own use?

* * *

NOTHING thus far set down can be construed as giving the seller the right to perpetrate a palpable fraud. Misrepresentation of the deliberate and premeditated sort is not authorized by law, but failure to point out incapacity for the purchaser's service cannot be construed as misrepresentation. The vendor, in offering a machine, necessarily takes into account the character of machine he has to sell, nor can he be expected to waste any time upon the vendee's question of service, unless he sees fit.

* * *

THE most successful companies in the world are numbered among those which do take the greatest possible interest in the ability of their wares in service, and the absolutely gilt-edge commercial companies positively refuse to permit their wares to go out without knowing what they are to be used for, or without knowing whether or not they will serve properly in that service. This policy works out in the automobile business just as it does in other commercial pursuits, and in the long run when the roll call of the survivors is concluded it is not believed that there will be one among them if its policy is based upon *Caveat Emptor*.

* * *

ONE of the points brought out at the Summer meeting of the Society of Automobile Engineers referred to the "cold end" of the pyrometer as used in heat treatment work. If indications are reasonably conclusive, the chances are that quite a number of those who rely upon pyrometers for the proper determination of heat-treatment temperatures neglect to maintain the cold end of the pyrometer at the melting point of ice (0 degrees centigrade). In the article on pyrometers now running in THE AUTOMOBILE it is clearly indicated that failure to maintain the proper temperature of the cold end results in the maluse of the instrument.

* * *

IN attempting to get away from the so-called "rule of thumb" practice of the old line shop man, it will be well to substitute something more accurate than that due to experience. The old-fashioned manipulator of the heat treatment equipment has a keen eye, and he makes up in cleverness for the defect in his empirical method. Substituting a pyrometer, if it is not properly employed, constitutes the most direct method by which a poor result may be obtained.

* * *

IT will be a step in the right direction if the various makers of automobiles will afford to their engineering staff an opportunity, including the necessary time, to become thoroughly acquainted with the instruments of precision they are supposed to employ in their regular work, the pyrometer being but one of the number.

Economics

DEALING WITH THE FUTURE PROSPECTS OF THE AUTOMOBILE INDUSTRY, DISCUSSING NEW FIELDS AND MORE THAT HAVE BEEN BUT POORLY WORKED, IF AT ALL

DESPITE the pessimistic views of those who least understand the automobile business, but have the most time available for its discussion, the future of the industry is on a settled basis. There are dozens of fields that are crying for attention. Moreover, it will be some time before the makers of automobiles will have an opportunity to work into the newer fields. Take, for illustration, the question of fire department equipment. Every fire department in every city and town in the land will adopt the automobile sooner or later, and the only reason they have not done so up to the present time is because they could not get the equipment.

* * *

WHEN a fire breaks out its automatic progress is picturesquely startling, and the amount of damage a first-rate fire will do in a short time greatly exceeds the rate at which money can be drawn out of a bank by a panic-stricken mob of depositors. It is a little difficult to quench the thirst of a depositor for his money in the face of a panic, but a fire responds to prompt application of stout streams of water. It will be understood, however, that promptness is of far greater virtue than water when a fire is to be quenched, and the automobile type of fire-fighting equipment is conspicuous for its ability to serve with dispatch.

* * *

IT is a matter of absolutely no consequence as to the first cost of the fire apparatus; the sole argument worth taking into account has speed for its foundation. Automobile fire apparatus is inherently endowed with speed, nor is it less capable in the measure of the streams it will throw when the scene of action is reached.

* * *

AUTOMOBILE makers are not waiting for municipalities to awaken to the virtues of automobile fire-fighting equipment; the reverse is true. Enlightened municipal officials are doing their best to procure the equipment; they will have to wait until automobile makers have time to produce it. Fire Commissioner Waldo, of New York, having investigated the virtues of the automobile type of apparatus, endorses it in all its phases, going the length of stating that gasoline underbids oats when it comes to cost. Announcing that bids will be advertised for a quantity of automobile fire equipment, the most progressive Fire Commissioner that the City of New York has honored for a long time expresses the hope that every engine house in the "Five Boroughs" will soon be equipped with automobile fire-fighting apparatus.

* * *

ALL the fire departments in the land, were they to be equipped with automobile apparatus, would fall far short of the necessities if the automobile business is to continue and prosper. The value of the equipment required for Greater New York, for illustration, might be put down as $100,000,000, which is a comfortable sum, but small, as the automobile business is measured. If fire departments are efficient to the extent that they save property, they are no less valuable to the community at large than the equipment employed in the cleaning of streets. The mortality in a great city is only kept down by everlasting vigilance and municipal cleanliness, which calls for efficient equipment.

* * *

THIS field, from the automobile point of view, is virgin, but it is large, and fortunately for the makers of automobile equipment, the contractors who handle this class of work are under the influence of the opiate which is extracted from lack of knowledge. When these contractors discover that they can do more and better work at a lower cost, using automobiles, than they can in the old way, the automobile industry will have at its disposal a coterie of willing purchasers, who will look upon automobile salesmen as mere obstructionists.

* * *

MUNICIPAL work is by no means the basis for the substantial outlook of the automobile industry. It may not be generally understood, for instance, that 25,000 tons of coal are handled daily in the City of New York by automobiles; there is no telling what the demand will be when contractors in general become acquainted with the facts as they are.

* * *

FORTUNATELY, inertia must be overcome before the demand will spread and become general, but it is a pitiable sight to call at the training camps of the army, there to observe that transportation is scarcely different from that which obtained with Grant in the Wilderness. But the army mule will have to go, although it is possible that the situation will not become acute until the mule's friend is placed securely upon the retired list. So far as the automobile business is concerned there is no hurry at all. Besides, the mule régime in the army has been one of conspicuous and honorable service.

* * *

IN the meantime, foreign armies are taking very kindly to automobile forms of transportation, and headway is being made at a rapid rate, now that immature and foolish ideas are being eliminated. During the creative stage the men who had charge of this class of work, although they knew that horse-drawn vehicles were incapable of supporting armor-plate, did not have the sense to understand that automobiles are substantially in the same fix. The natural inference was that automobile trains for army work would fall short of the best requirements, as measured by the standards of the day, unless they could be made bomb-proof, although the men who established the standards made no attempt to state how they would fasten armor to horses and obtain result.

AT THE CROSSING OF THE WAYS BY AN OBSERVER; WANTS TO AIR A GRIEVANCE; TAKES UMBRAGE AT A HALF-BAKED PLANETARY GEAR; MAN WANTS TO BECOME A CHAUFFEUR, ETC.

At the Crossing of the Ways.—Pedestrian was angry. The bluecoat ruler of the traffic has whistled when Pedestrian was in the middle of the crossing. The taxicabbies and chauffeurs had driven ahead as if Pedestrian did not exist. He had been obliged to jump to reach the sidewalk and his dignity was ruffled; in fact, he was red in the face and trembling with rage. "The pack of ruffians," he mumbled audibly, including the bluecoat and the whole automobile world in one sweeping glance of denunciation.

The man who conducts an automobile is not always highly considerate. But he bears comparison smilingly with the high-perched teamster whose quids and invectives hit where they may, with the wanton spitter from rear platforms, with the hustler of packing boxes and with many others whose ready insolence springs from the possession of tools that may be turned into arms as deadly as the automobile. Even in a round-up of policemen and chauffeurs it may be doubtful if there would not be as many polite ones among the latter as among the guardians of peace who draw pay for being helpful.

Pedestrian himself, when his rage brims over, intimates what *he* might do to help the situation if he were equipped with means for holding his own against the superior momentum of the offenders. Moved with compassion for manufacturers of whips who have lost much trade since the automobile came in vogue, he might unite with himself and form a society for the popularizing of the combined walking stick and *chambrière,* or he might prefer the rawhide dog whip, and whenever a cocksure driver of the hated automobile threatened his ambling leisure he, too, would draw arms, presumably. Oh, but what a smarting slash would mark the cheeks of that chauffeur! Or, Pedestrian with a real grievance, and studying for vengeance and prevention, might discover that shining little steel pellets, exact spheres within 1-500 of one inch, though not good enough for automobiles, may be bought for 30 cents per thousand and, handy from the pocket, would make excellent missiles, carrying a message of chastisement to the facial cuticle of his foes. A *corpus delicti* would be almost as hard to find as an absconding witness in a political trial.

Between retaliation in kind and religion in spirit the resources of Pedestrian are by no means exhausted. Philosophically he may set himself the task of deciding which end of his dilemma will cause the lesser amount of vexation. Then, too, he may follow the example of the intelligent Sarah Bernhardt, who as early as 1900 detested automobiles and forthwith mortgaged her next performance and bought a car for the proceeds. She was as wise as Mohamet who went to the mountain when it would not come to him.—Observer.

Wants to Air a Grievance.—As you appear to be entirely willing to discuss any questions your readers bring up, I will air my grievance. Will some one kindly explain why it is that although the manufacturers of motor cars keep on steadily improving their machines in every other way, none of them ever think of improving the pan under the engine, but continue to use the same pattern of mud pan as Nebuchadnezzar used on his chariot? Of course. I cannot swear that every machine manufactured is deficient in this respect, but every one I ever had any experience with is the same way—a roughly and poorly constructed sheet of sheet iron fastened on with hooks or clips, there being only one job on earth harder than removing it, and that is getting it back on again. As for the pan on my own car, I couldn't express my opinion in language fit to go through the mail. A number of these monstrosities get bent all out of shape by the time the car has been run two or three thousand miles, and scrape against the flywheel or other parts of the motor. It always looks to me as if this was a place that they were compelled to cover in some way and were at a loss to know how to do it and accordingly were obliged to let it go through with the first makeshift device that came to hand.

I don't know about the auto users in general, but for my part I would gladly pay a little more money on my next car and get a part constructed to fit its place in this section of the car instead of a thing resembling a piece of tin roof after a bad fire. There does not seem to be any reason why the pan cannot be constructed to retain its shape, either by making it of inflexible material or building it over a light, stiff frame, and also to make the front portion of it to fit into grooves or over lugs so that it may be put back into position without the aid of a surveyor and a crowbar.

This may seem like a silly kick, but I feel sure that there are plenty of people driving cars who feel the same way about this as I do, and I do sincerely believe that in at least fifteen makes of machines, and probably others, there is a pan provided that ought to be legislated against.—R. W. McDowell.

Takes Umbrage at Half-Baked Planetary Gear.—Will you allow me a little space to record the very low opinion I hold of some planetary gears?

I have often wondered why makers put some of these contemptibly inefficient gears in automobiles costing so much that the extra cost of good gears would not increase the cost of the car more than 5 per cent. Some makes are different, and give satisfaction; but I have one of those cars whos surname might well be Blarneyite, but isn't, and whom Mr. Unoften accuses of not paying royalties on the Unoften patent. Well, it is the third car I have owned, and I would not give 30 cents on the dollar for my choice of his whole output, if I had to take the ensemble of the planet along with it in the shape of a transmission.

How is it a nuisance? In more ways than an ingenious inventor of fiction could imagine. In the first place the noise of the low gear is like unto the dumping of a garbage load of tin cans. An editor of a leading automobile journal has said that a motor car is worn out when it gets on the nerves of the owner. Measured by that criterion, my car has already enjoyed twice seven lives. Again, the gears require constant adjusting. I have to tighten up the low in order to climb a hill, and, if I get it the least too tight, the high drags so that I can't climb any kind of a grade until I loosen the low. Also the high requires frequent adjustment regardless of the condition of the low. As a Pandora's box of troubles carries off the whole peach crop of Oregon.

And to think it's just because the maker wishes to squeeze a little more profit out of his cars in addition to the royalties he is beating Mr. Unfrequent out of. I was talking to a physician lately about what cars are the best to buy to-day. He is also the owner of a screecher, and he said he wouldn't buy another. We were unanimous on that point, and both our objections were founded on the transmission. He spoke of a neighbor of his having another, and said that he could hear that neighbor leaving for his office every morning. I had had a neighbor whose morning departure I could also note, and, at times, his going was the cause of my waking. Say what you please about light cars needing only two speeds, but take my word for it that any car which is intended to road it in this section needs a very low gear—I would call it an "emergency low." Two gears are usually enough, but it is the unusual happening that causes the motorist to hire a team once in a while and that costs money.—S. Ross Parker.

Mester Editer.—Jag vant yob for shofer. En Salvation lady. vant me vork for salvation men jag sa: No, jag vil work shofer. She sa: You vork shofer och vork for salvation samma time. Jag sa: No, no man kan vara shoper och vork for salvation a samma time.

Jag ban til shoper schoola samma time ven jag vore in hospital met en broken leg. Jag ban marrit tirty year och jag er sober man yet. Jag vork met mashiner somme time. Jag see man draiv kar ofver bank, men jag know ven to turna hveelet. Jag har drifvet oxen. Jag kan vorka unner car. Jag haf dig ditch unner hous. Jag vant goot yob met fine close och blanka buttons. You get me yob for shoper, och jag gif you mit pikter som jag yoost haft takit.—Eric Ericsson.

Expert's View of the Trade.—There is no question but that a certain amount of anxiety that has prevailed all along the line within the past two months in the automobile industry, has been justified but the conditions which have brought about this anxiety have been the logical result of a certain trend of events which have not been under the control of the automobile manufacturers. In the past, the automobile business has been a season business, (i.e) the manufacturer attempted to build a large number of cars in two or three months during the selling season, with always the same result—that it was found absolutely impossible to fill orders.

This year the majority of manufacturers ran their plants at full force during Fall and Winter, storing up some cars with the expectation of being able to come nearer to filling orders during the Spring season by drawing on this storage stock. Without doubt this would have been a wise move had it not been for the exceedingly inclement weather that prevailed during the Spring and early Summer months and which made it impossible for the agent to dispose of cars, as he could readily have done had the weather been normal.

The factories, however, have been running at full force until this year's production was practically completed, which in most cases was much sooner than expected, owing to the early start made by the different companies. This, therefore, necessitates a temporary decrease in the number of cars produced daily by the manufacturers until the 1910 season has been ended and until they can get ready for the 1911 models.

The banks have discouraged the farmer and the small agent by refusing loans on anything pertaining to automobiles. The wonderful crops in the west have enabled the farmer (and, of course, the people he comes in contact with) to buy automobiles without recourse to the bank and, as the farmer looks upon the automobile now as a necessity and not with the feeling of antagonism shown in former years, there is no question in my mind but what the Fall purchases of machines will be greater than ever before known.

I am confident that the 1911 season will see more automobiles manufactured and sold in the United States than ever before.—Fred W. Haines, General Manager of the Regal Motor Car Company.

Why Country Bankers Object to the Automobile—We hear a great deal nowadays of the non-productive capital which the money invested in automobiles has withdrawn from useful purposes. It is true that the depreciation on an automobile must necessarily represent a shrinkage which cannot be overcome, but aside from this natural depreciation, do not the dollars and cents put in automobiles represent vast industries, with well-paid workmen, skilled mechanics, intelligent salesmen, and enterprises radiating from this business through hundreds of different channels and industries?

We have 70 agents in the United States. A careful investigation of our retail business reveals not a single instance of a car sold, where the funds had to be derived from a mortgage, either of the car, or upon the home of the buyer in question.

Investment security sellers, small town bankers and stock brokers are not blaming the automobile as a source of injury to the country, but simply because they can point to the heavy purchase of motor cars as the item which has affected their individual profits, and a great many people are apt to judge the welfare of their country by their individual affairs.

Take, for instance, an Iowa town, of, say, 2,500 people with a rich farming community contiguous. You will find say six banks, with aggregate deposits of $500,000. This, I think, is considered a good average. Good banking calls for at least 25 per cent. of this to be kept in reserve, the remainder no doubt being loaned out on farm mortgages, live stock, term notes or high-grade investments. The reserve, though, was very seldom kept at home but a very considerable portion of it is invested in Chicago, St. Louis, Des Moines or Kansas City banks in the shape of deposits upon which they receive between 2 and 3 per cent. interest.

In such a country it has been no uncommon thing for 100 automobiles to be placed in one year. A safe estimate would average the cost of these cars at $1,000 apiece, or a net total sum expended on motor cars of $100,000.

It is, therefore, obvious that the deposits in the six banks referred to above have shrunk $100,000, and the money left the community. Since the money has merely been transferred to some manufacturing center, there is no loss in the country. The local financiers, though, have lost all but $25,000 of their reserve and instead of sitting back complacently as a depositor in Chicago, St. Louis and Des Moines banks, and drawing 2 to 3 per cent. interest on the other fellow's money, he is forced to go to the same bankers and borrow exactly the same amount that has left the community and pay generally between 5 and 6 per cent. for it, or curtail loans, and hence earnings.

It is, therefore, apparent that nobody has lost any money except the banker. His business is not as profitable as it was before, because his depositors are not keeping the idle money in his bank, and he is not getting the use of it.

History shows that every tremendous step forward that the world has taken has been due to some radical improvement in transportation. The Roman carts subdued the Pagans. Napoleon's swift marches overran Europe; the steam engine and the steamboat made America and the United States, and without them, St. Louis and Chicago would still be fur-trading posts. So also to its own degree will the automobile revolutionize transportation, improve farm values, and create untold benefits, and it is hardly justice to the automobile industry to hold up the few exceptions, as horrid examples and blame the automobile for conditions which it is not responsible for.—Joseph W. Moon, president Moon Motor Car Company.

Automobile Vogue Menaces "Confidence" Industry.—In the current issue of *Farm Machinery*, a publication devoted to the interests of that trade, a leading position is given to a symposium of alleged and anonymous bankers on the subject of the danger that menaces the financial, moral and political existence of the country through the vogue of the automobile.

Half a dozen bankers who have grown so used to drawing down 2 or 3 per cent. on legal reserve have forgotten that depositors still have the right to do as they please with their own property, and bewail the fact that the depositors have withdrawn this surplus money.

But one banker from Keokuk, Iowa, told the truth, even if it was an unpalatable mouthful. He is quoted as saying: "Money formerly lost in speculation in mining and other worthless stocks is now invested in automobiles, and this city now has one automobile for every 100 of population."

This should prove a valuable pointer to industrious "con" men who contemplate a campaign in that delightful section of the country. If the general public has advanced so far along lines of worldly wisdom in Keokuk, that it prefers the sensation of riding in an automobile to the desperation that follows investment in fake securities, lighting rod contracts or even the feeling of misery that results from failure of banks following the unsuccessful speculation of the bankers in Wall Street or elsewhere, it is time to seek other fields.

The automobile undoubtedly cuts out funds that might feather the nest of "green" goods swindlers, but the fact should be remembered by the bankers and green goods men that the owner of the money may do with it what he pleases and the record shows that he pleases to play with the automobile rather than to furnish "fat" for the carrion buzzards who so long enjoyed unearned the fruits of his labors.—Reviewer.

The Munsey Run

HISTORIC TOUR STARTS FROM PHILADELPHIA NEXT TUESDAY. WILL BE THE MOST IMPORTANT ENDURANCE TEST OF THE YEAR. ROUTE LIES THROUGH TERRITORY RICH IN HISTORIC INTEREST AND SCENIC BEAUTY.

OVER a route laid out through ten States, which saw a large part of the history-making events of the early days of the Republic, the Munsey Historic Tour of 1910 will start from Philadelphia next Tuesday. For the next dozen days the long string of automobiles entered in the tour and contest will wind in and out among the scenes of struggles that are written immortally upon the tablets of the nation's remembrance.

The territory covers a thousand points of patriotic interest, the least of which contains enough of fascination to center attention in passing, while the names of a dozen of the more important points are sufficient to set the pulses thrilling. The route of the tour follows one road in New Jersey where Washington and his frost-bitten soldiers swooped down and captured two garrisons of mercenary troops, out-generaled the relieving columns of the British commander and faded away in the night behind the protection of unguarded camp fires. In another place it follows the route taken by Benedict Arnold in escaping to the boat landing below West Point, from which he succeeded in gaining the deck of the warship *Vulture*. It goes over the old Boston Post Road in Connecticut and through the historic territory of that State to New London, which was ravaged by Benedict Arnold, after he had taken up arms for the British cause, and thence through Rhode Island to Boston, touching a hundred spots of national importance in the formative years of the Republic and the scenes of numberless encounters with hostile savages in a still earlier period.

The very name of Boston is thrilling to the red-blooded American, no matter what section of the land he may claim as his home. There it was that the militant spirit of revolution was fostered; there it was that the Pilgrims landed about three centuries ago and there it was that the impetus of armed resistance to tyranny found expression long before the actual declaration of hostility against the injustice and aggression of George III. Bunker Hill and the glorious defeat sustained by the infant nation, in which the Americans discovered that their enemies were merely men and that the missiles of their squirrel rifles would make even the British regulars waver and run before their spiteful stings, will be particularly noted by the tourists.

From Boston the way follows the rugged coast of the Ocean, through New Hampshire and Maine to the city of Portland and thence striking westward it climbs through the foothills until the heights of the White Mountain country have been attained. Passing through the Green Mountains of Vermont to Burlington, the Sunday stop-over having been made at Bethlehem, N. H., the tourists will approach Lake Champlain on the seventh day of actual running. The course of this day's run is particularly attractive, as it is laid Northward over several of the islands in that beautiful body of water, to the upper end, where the cars will be ferried to Chazy on the New York side. Turning Southward, the tourists will proceed toward Saratoga over the roads used by Burgoyne during the invasion from Canada, in that ill-fated campaign that proved the turning point in the fortunes of the Revolutionary War. The cars will pass various points where the distracted British troops, decoyed farther and farther from their base of supplies, puzzled with false information and bewildered by forays of the Americans, finally yielded.

From Saratoga to Binghamton the way is through the land that was known as the "Bread Basket of the Nation." during those early days. It is the country that was settled by pioneer farmers long before the struggle for Independence and proved to be of marvelous fertility and agricultural potency. Dotted across the map of this day's run are the names of hamlets and localities that were the scenes of horrible Indian massacres.

Southward from Binghamton, the road is to Wilkes-Barre and the actual route of the travelers is via a stretch of highway that was built by General Sullivan and his Revolutionary soldiers during the campaign in which he had been commissioned to punish the Indians for an atrocious massacre inspired by the British and Tories. This bit of roadway was constructed with immense labor and while it is passable to-day, it will undoubtedly prove to be the most trying stretch of the tour.

Coming into the homestretch the tourists will leave Wilkes-Barre and the run to Harrisburg is one of the best scenic bits of the whole journey. The mountains of Pennsylvania are rugged and difficult and this portion of the run will give a supreme test to the cars entered, coming as it does after such a long and trying trip. The last day of the tour is to Washington, D. C., where the cars will be checked in. The total mileage is about 1550 and the whole route has been picked out with the idea of giving a wide variety of road experience.

Entirely aside from the historic interest of the tour, the contest feature as a reliability test of the automobile will be valuable and illuminative. Most of the roads are excellent, but enough stiff grades and difficult highways have been included to test the stamina of the entered cars.

The Munsey Tour is fathered and managed by the Munsey newspapers, *The Washington Times, Baltimore News, Philadelphia Evening Times* and the *Boston Journal.*

It is fully recognized and sanctioned by the Contest Board and this year has received a vast amount of attention from manufacturers, as is evidenced by the magnificent entry list. There are several more makes of automobiles represented in the list than contested in both divisions of the Glidden Tour of 1910 and a number of the leading contestants in that event will be found in the Historic Tour.

A spirit of fairness and consideration has been apparent in all the official actions of the management during the preliminaries. Everybody connected with the enterprise has been working to anticipate problems likely to arise during the run and to prepare to meet them justly.

The officials of the tour are E. L. Ferguson, of New York, referee; Technical committee, E. L. Ferguson, Joseph Tracy and J. A. Hemstreet, Harry Ward and M. M. Mauger, of the Munsey papers, will be in charge of the two pilot cars and Francisco Juarez Byrne, the noted Spanish-American author, will write the newspaper reports for the Munsey string.

From present indications there is not a shadow to darken the prospects for a successful tour. The route is ideal. It lies through a territory closely in touch with the great centers of population. It is sufficiently varied to give an adequate test of the machines without torturing cars and drivers and passengers. The officials are among the most competent in their line of business and the field is about as good as any that ever went to the post in a similar contest.

The entry list includes the following: Premier, Columbia, Maxwell (3), Washington (2), Reading "40", Ford (3), Elmore, Warren-Detroit, Corbin, Spoerer 1911, Brush runabout (2), Regal "Plugger," Pierce-Racine, K-R-I-T, Enger, Great Western, Cino, Ohio, Staver-Chicago, Stoddard-Dayton, Crawford, Glide, Moon, Kline, Matheson, and Inter-State. All these are in the contesting class. A Randolph truck has been entered as a non-contestant to carry baggage as well as a Reading "6" and the officials' cars include an E-M-F, pilot and press car; Selden, pilot; Columbia, pacemaker; American Roadster, starter's car; Thomas, press; Washington, press, and Brush, photographer's car.

The Elgin Races

CHICAGO MOTOR CLUB PREPARING FOR THE TWO-DAY ROAD RACING CARNIVAL TO BE HELD OVER ITS NEW COURSE ON AUGUST 26-27. LIST OF OFFICIALS AND MAP OF COURSE.

STARTING August 26, and continuing over the following day, national stock chassis races of the simon-pure variety, and conducted over a typical road course will be held on the Elgin, Ill., raceway, and the winners of the various events may well lay claim to the national road racing championships.

The plans of the Chicago Motor Club in conjunction with the Elgin Automobile Road Race Association are in full blossom which will come to fruition the latter part of this month.

Official sanction was only recently granted, but within a few hours after the announcement had been made entries and the promise of entries began to pour in.

Arthur Greiner, an amateur, has named a National for the Elgin National trophy race, and the National Automobile Company, of Chicago, has entered a National for the Illinois trophy. Two Coles have been named by telephone from Indianapolis, and a Ford car has been entered by the Chicago branch, while assurances are given by the Lozier, Benz, Renault, Marmon, E-M-F, Parry, Falcar, Black Crow, Oldsmobile, Herreshoff, Cino, Matheson, Velie, Marion, Alco, Corbin, Simplex, Jackson, Midland and Stover, that they will make nominiations. The Lozier, which has been out of road racing for a couple of years, has gone so far as to secure headquarters at Elgin, which is taken as a guaranty of the company's serious intentions.

Chairman Harry T. Clinton and his associates on the Contest Board of the Chicago Motor Club have selected the officials who will handle the National Stock Chassis Road Races as follows:

Honorary referee, C. H. Hulburd; referee, David Beecroft; judges, F. C. Donald, Everett C. Brown, T. J. Hyman, W. C. Thorne, W. F. Grower, A. J. Banta, F. W. Jencks, G. E. Hunter and Frank H. Trego; starter, Fred. J. Wagner; assistant starter, Oliver G. Temme; clerk of the course, Harry T. Clinton; assistants, W. J. Zucker and J. S. Woodworth; technical committee, A. E. Edwards, Berne Nadall, Otto Von Bachelle; timers, C. H. Warner, J. P. Frisby, R. T. Laughlin, H. W. Cooper; chief checker, John H. Kelly, assistants, L. Z. Sheldon, Ralph Hoagland, W. Nussbaum, Frank Sparks, Ed. Guston, O. L. Foote, Hosmer H. Allen, Lyle Miller and L. R. Campbell; chief scorer, Charles E. Gregory; chief flagman, Frank B. Wood; military aid, C. A. Tilt; chief announcer, L. B. Sanders; chief electrician, Al. Adams.

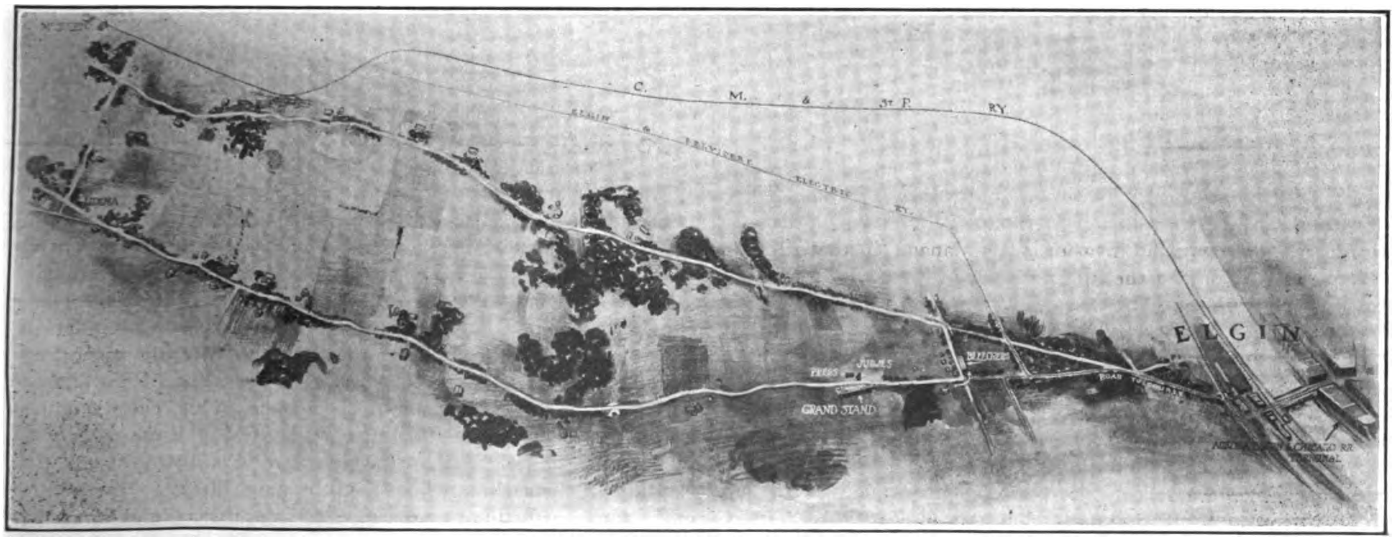
At the same meeting it was decided to postpone the club's annual hill climb at Algonquin, Ill., the new date selected being Thursday, September 15. This action was taken because it was found that it would be impossible to finish by September 10 the artificial hill which will be used for the standing start climb.

The club has had trouble getting Perry Hill for this, the grade being in another county. The Algonquinites, however, have promised to build a special hill 1,000 feet in length and which, it is said, will be one of the stiffest propositions a motor car ever has been called upon to tackle. Ten teams and twenty men started at the hill immediately; it will be done by September 1.

The motor club has received the design of the Elgin National trophy, which is to be the prize in the big race the second day, the event for cars under 600 cubic inches piston displacement. It is best described as a classic vase, 3 feet 8 inches high above the pedestal. It is a two-handled cup, the main decorations being the laurel oak and water leaves. This cup is designed to take six wreaths with inscriptions and two panels, one for the motor car scene on the obverse side, and on the reverse side the main description of the cup. On the neck of the cup is the figure of Father Time. The trophy is valued at $4,500.

The Chicago Motor Club and the Elgin Automobile Road Race Association have decided to sell the seats at popular prices. They have formed a combination with the property owners, so that everyone who sees the races will have to pay 50 cents. Then grand stand seats will be sold for $1 for each day; box seats will be sold at $1.50 each, while bleacher seats can be made for 50 cents. Parking spaces will be sold at $1 per car. The seating accommodations will be for 7,000 people, but more can be added if needed.

The course has been found to be 8 miles, 2499 feet in length.



Bird's-eye view of Chicago Motor Club's National Stock Chassis road race couse at Elgin, Ill.

Commercial Car Run

NEARLY FOUR-SCORE ENTRIES FOR THE MOST IMPORTANT AFFAIR OF THE KIND EVER HELD IN THIS COUNTRY. THE CONTEST WILL SURELY DEMONSTRATE UTLITY OF BUSINESS VEHICLES.

WITH a probability of seventy entries, representing many styles of commercial trucks and freight vehicles, the endurance contest under the auspices of the Philadelphia *North American*, which will be run August 12 and 13 from Philadelphia to Atlantic City and return, is attracting wide attention.

The idea of the contest is to demonstrate the ability of the truck to make a time schedule with economy of fuel or current, and the newspaper has offered prizes aggregating $1,000 for the winners. The running of the affair is in the hands of the Quaker City Motor Club. The roads selected for the trial are in excellent condition, but in order to show that the cars can surmount ordinary road difficulties, several trying stretches of highway have been included in the itinerary.

The distance to Atlantic City is about 62 miles and under the plan that has been worked out the gasoline cars will be divided into four classes. In class A, a schedule of fifteen miles an hour will be required. This class is the manufacturers' division for trucks of 1 1-2 tons capacity and less.

In Class B, with capacity of from 3,001 to 5,999 pounds, a running time of twelve miles will be asked. In Class C, from three to four tons, ten miles an hour must be made and in the same class, but for cars of over four tons capacity, the schedule calls for eight miles an hour.

In the electric division, Class A must make 12 miles an hour; Class B, ten miles and Class C, eight miles an hour. An accurate record will be kept of the gasoline and oil used by the gasoline cars and of the electric current used by cars of that variety and due allowance will be made in computing the result.

The cars are all required to carry their advertised loads and the figures on the proportionate consumption of power will give a basis of cost of transportation.

The list of entries to date includes the following:

MANUFACTURERS' DIVISION

Class A (1½ tons capacity and less)

Car	Entrant	Driver
Strenuous Randolph	Randolph M. C. Co.	R. G. Shuert
Chase	Commercial M. C. Co.	W. F. Wood
Chase	Commercial M. C. Co.	R. L. Ferris
Franklin	Franklin M. C. Co.	W. R. Coughty
Martin	Martin Carriage Works	E. L. Kraft
Martin	Martin Carriage Works	John M. Bowers
Torbenson	Torbenson M. C. Co.	Allen Torbenson
I. H. C. Wagon	International Har. Co.	W. A. Bauer
I. H. C. Wagon	International Har. Co.	Daniel B. Shock
Buick	Buick Motor Car Co.	Hubert Cato
Buick	Buick Motor Car Co.	William Thompson
Atterbury	Finnesey & Korber	M. Korber
Chase	Commercial M. C. Co.	W. J. Burns
Rapid	Rapid Motor Vehicle Co.	James Parrey
Hartkraft	Hartkraft Mot. Truck Co.	R. B. Lawrence

Class B (between 3001 and 5999 pounds capacity)

Car	Entrant	Driver
Garford	Garford M. Truck Wks.	Mr. Ritter
Grabowsky	Edgar W. Hawley	G. G. Stranahan

Class C (three tons and above)

Car	Entrant	Driver
Frayer-Miller	Kelley M. Truck Co.	Harry Weber
Schleicher	Schleicher M. V. Co.	Alfred Besser
Standard	Standard G. & El P. Co.	W. Hunsburger
Gramm	A. E. Gardiner	Archie Nobb

Croxton-Keeton Motor Company Will Come Back

H. A. Croxton, president of the Croxton-Keeton Motor Company of Massillon, O., which was thrown into the hands of a receiver August 1 on Mr. Croxton's application to the Federal Court at Cleveland, was in New York Tuesday making arrangements looking to a reorganization.

According to Mr. Croxton the receivership will be lifted within sixty days and the 1911 line of cars will be ready for market by September 15. He stated that the troubles of the company were due to a disagreement between some of the officers and that he only resorted to a receivership in order to protect the creditors from ill-advised and hasty action.

He says that the assets of the company, pruned down to the last degree, amount to $295,000 and the liabilities are $273,000. Mr. Croxton says he is the owner of 90 per cent. of the stock of the company. P. L. McLain has been named as receiver.

Garage Owner Charged with Swindling

Edward Underhill, proprietor of the Garage de Luxe, 57 East 108th street, and Henry Roy, chauffeur, employed by Underhill, were held to Special Sessions last Friday by Magistrate Cortel of the Harlem Court on a charge of violating the short-measure ordinance. Bonds were fixed at $500.

Inspectors Mills and Morgan are the accusers of Underhill and his employee. They charge that on July 16, while inspecting garages, they stopped at the place of Underhill and purchased what purported to be ten gallons of gasoline. This, they say, did not measure up to the full amount by two gallons.

The officers declare that the shortage was brought to the attention of Underhill, who failed to have his gasoline pump repaired, and after the passage of a few days warrants of arrest were sworn out and bail fixed at $1,000 each, the Garage Owners' Association taking an active part in the prosecution.

Some 1911 Automobiles

(*Continued from page* 219)

point. Models 31 and 32 differ from 1910 designs in that the bore of cylinders is increased from 4 7-8 to 5 inches, bringing the cylinder dimensions to 5 x 5 1-2 inches. In model 31 the wheelbase is 1 inch more than in the previous model, bringing it up to 123 inches. In the ignition system the Bosch high-tension magneto replaces the low-tension type previously used. This change simplifies the dashboard equipment materially, cutting out the induction coil formerly employed in the low-tension system. A means is provided in the new cars for the independent operation of the magneto, or auxiliary ignition. A Yale lock is incorporated into the switch, securing it in the neutral position when the car is shut down, and affording excellent protection to the owner of the car by preventing a purloiner from closing the electrical circuit of the ignition system. Lubrication is reduced to the most simple form, involving the splash method and a circulating means. There are two splash compartments in the four-cylinder motor, and the hand pump provided is so arranged that the supply of oil may be replenished in either of the compartments independent of the others. The plunger pump used for circulating is located at the bottom of the case and is driven by a gear taking power from the camshaft. In view of the increase in the size of the motor the dimensions of radiators were adjusted in conformity with the needs, and the extent of refinement at all points in these models is carried even to the length of locating the battery in a suitably contrived compartment inside of the chassis frame in a protected position beneath the floor boards of the tonneau. Dress guards cover the forward end of the rear springs, thus facilitating access and improving the appearance of the models. The front fenders are brought to a higher state of perfection and take the curvature of the front wheels, presenting an artistic appearance. The steering column is provided with an 18 1-2-inch hand steering wheel mounting the spark and throttle control of the same design as last year. The clutch of the internal expanding leather face band type is the same as formerly, and the connections from the foot pedals are with ball and socket jointed rods. Transmission gearsets are of the selective type and the mechanisms for manipulating and locking the gears are enclosed within the case.

In the Flanders "Twenty," made by the E-M-F Company, Detroit, the motor is of the "bloc" type with four cylinders, bore 3 5-8 inches and 3 3-4-inch stroke, with the valves located all on the left side, making the block casting of the L-type. The lubrication in this motor is what is known as the vacuum type, designed for a constant level with a gravity feed. Cooling is with water, using a gear-driven centrifugal pump, aided by a vertical tube radiator and a fan driven belt. Ignition is of the jump type with a Splitdorf magneto and auxiliary coil. The carbureter is of the float feed type with auxiliary air valve and gravity feed. The clutch is of the inverted cone type with a leather facing against cast iron, and the selective sliding gear, with two forward speeds, and reverse, is swung on the rear axle.

The Inter-State motor, made by the Inter-State Automobile Company, Muncie, Ind., is of the four-cylinder type, rated by the makers at 40 horsepower, with a 4 1-2 inch bore and 5-inch stroke. The cylinders are of the L design, cast in pairs, with all valves located on the right side. Lubrication is by constant level splash maintained by a gear pump which is shaft driven. Gravity feed is relied upon for the rest. The water-cooling system includes a circulating pump, honeycomb type of radiator and a belt-driven fan. Ignition is by jump spark with a double system, including a U & H magneto and dry cells in conjunction with a coil for the auxiliary system. A Stromberg carbureter with a gravity feed takes care of the full situation. A multiple disc clutch with cork inserts takes the power from the motor and delivers it at the will of the operator to a selective sliding gearset, located amidships, affording three forward speeds and reverse. From the transmission gear to the live rear axle a shaft is used.

In the Franklin product as made by the H. H. Franklin Manufacturing Company, Syracuse, N. Y., four models of open cars are offered for the new year, two of which are "sixes" and two are "fours." One of the Franklin bodies is given in the plate of body illustrations. It is of the full flush-sided type and is an excellent illustration of the Franklin line, remembering, however, that the body work on the four-cylinder cars is a long conventional touring line. The new models are with increased wheelbase lengths, namely, 133 inches, 122 3-4 inches, 107 1-2 inches and 99 5-8 inches. The air-cooled motor, based upon the general design as brought out in 1902, is retained for 1911, subject to the modifications indicated by a year's experience. The method of cooling is substantially as in 1910 motors, including a metal air jacket surrounding each cylinder, and the cooling air is drawn from grilled openings located in the front of the hood, a fan in the flywheel being used for the purpose. In the several models of cars the cylinder dimensions are as follows: 4 1-2 inches x 4 1-2 inches, 4 inches x 4 inches (for two models) and 3 3-8 inches x 4 inches for the remaining models. Fiber gears are used for the camshaft gears, also for the magneto idle gear. The one great change of the year lies in the location of the valves. It will be remembered that concentric valves were employed in the 1910 motors, whereas this year the intake valve and the regular exhaust valve are placed side by side in the cylinder head. The new valves, operating separately, are claimed to be more nearly noiseless. An auxiliary spring is placed at the bottom of the valve lifters to hold the walking beam in constant contact with the end of the valve stem for the purpose of reducing lost motion and aborting noise. The auxiliary exhaust valve at the base of each cylinder is retained. A new oiling device is adopted; the oil is fed by a force-feed oiler through the crankshaft and into the engine base. Oil is introduced into cups on the internal base bearings, whence it runs directly onto the shaft through a groove and thence through a hole drilled in the shaft which extends through to the connecting-rod end. By centrifugal force the oil is passed to the connecting-rod bearings through oilways in the crankshaft. The cylinder walls are lubricated by a spray of oil as it is thrown off of the connecting-rods. Splash is depended upon to some extent to add to the profusion of oiling.

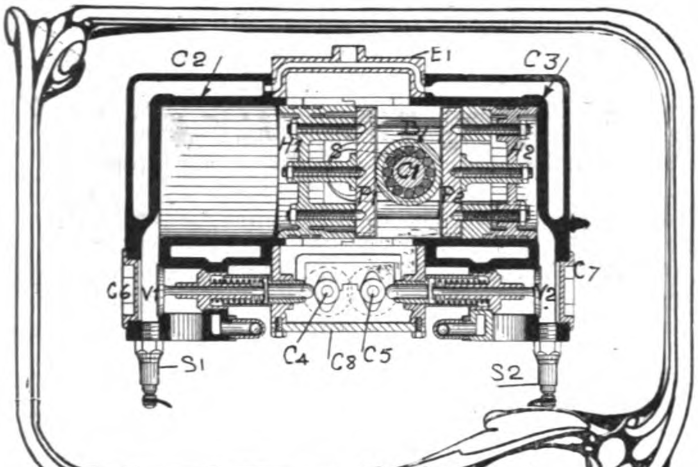
The Chalmers power plants, made by the Chalmers Motor Company, Detroit, remain substantially as in the 1910 models, excepting, of course, that the necessary shop process modifications have been made and are rapidly being brought to a high state of perfection, with the idea of inducing a greater measure of stability and adding to the uniformity of production. The finer methods of heat-treatment that come with the introduction of the latest and most approved pyrometers and facilities are available in the new addition to the plant, and matters such as this, while they do not make a change in the construction features of the output such as can be noted down in a dimensional way, do, nevertheless, constitute a material advance. The company states that mechanically the 1911 models are merely refined; a number of little changes constitute this refinement, rather than any radical departure. The "Thirty" motor is now being built in the plant of the company, and the material advance in its construction is by reducing vibration and improving the general appearance as well as the workmanship of the motor. In the "Forty" motor the valve springs are encased and noise is thereby muffled. The wiring system on both the "Thirty" and "Forty" models is much simplified and rendered more stable, otherwise the ignition devices remain as before on the "Thirty" horsepower model, but the "Forty" horsepower ignition system has been materially improved, the Bosch dual system of ignition with a unit coil and four spark plugs having been adopted. The improved Mayer type of carbureter is regular on the "Thirty," but the Stromberg carbureter is adopted for the "Forty." The constant level splash system of lubrication obtains in both models. On the "Forty," however, the gear pump has been supplanted by a plunger type of oil pump. The multiple disc clutch, using steel and bronze plates alternately, running in oil, is retained for the "Thirty," and the cone clutch is continued on the "Forty." There is no material change in the steering gear for 1911 over 1910.

Twombly Automobile

EXHIBITING to the representatives of the metropolitan press in New York City on August 8, the Twombly Motors Company, 220 E. 41st street, New York City, presented a new motor car with so many advanced ideas in it that it amounts to a revolution of the conventions. Whether or not the ideas incorporated into this car will consummate a revolution depends upon the judgment of the autoing public. The foundation of the new design is based upon the question of accessibility of the power plant as a paramount issue, and the convertibility of the body as an important consideration. From year to year many autoists have persistently maintained that a single type of body should be available, not only for fine weather in the Summer time, but with protective measures at hand should the weather become inclement. This school of autoists also maintained that in Winter autoing, protection of the first order should be afforded without having to buy a new automobile to get it. They also contend that when the Sun shines in the Winter time, and the invigorating atmosphere augurs for health, there should be some way of opening up the limousine and enjoying the invigorating conditions. The Twombly limousine offers all these attractions, and the designer has mastered almost insurmountable difficulties in the attainment of the objects. All that remains in this regard is for the company to place its product at the disposal of users and find out if they were in earnest.

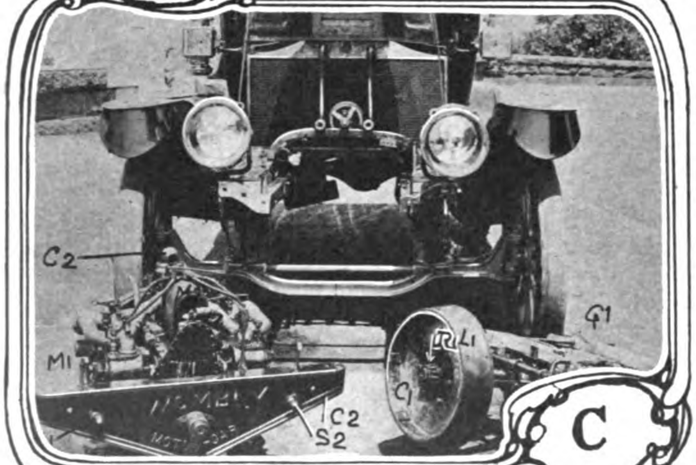
Despite the attractions offered by the type of limousine illustrated herein, the greatest change seems to be in connection with the power plant, in which the motor may be removed together with its accessories, inspected, if the occasion requires, and put back again within a few moments, it being light enough so that two men can handle it with ease. If it becomes necessary to remove the transmission gear also, it will come right out without having to unloosen a bolt or take down a bar. In re-assembling nothing remains but to replace the transmission gear first, and thereafter slide in the motor. The units re-unite with each other in satisfactory alignment and the transmission members take up their accustomed relations without the pursuasion of tools. When they are pushed back into place the locking studs are screwed up tight without having to make a water connection or in any other way tamper with the mechanism; the power plant will go about its business. The details of the power plant and the car as a whole are worked out to a fitting conclusion, and in short the designer of this automobile busied himself assiduously to satisfy a demand which seems to be pressing and forceful.

Among the mechanical features the cooling system is "thermal" and the bonnet is Renault fashion. Ignition is by Bosch Dual Magneto System, and the carbureter is of the float feed type. W. Irving Twombly, the designer of this type of car, having in mind the exigencies of taxicab service and town car work, has introduced another innovation in the form of enclosed helical springs in conjunction with dashpots for the suspension of the body, instead of the customary flat plate forms of springs typified in other makes of cars. The motor is in length equal to the distance of the cross members of the chassis frame, is 8 inches through in the vertical plane, and the cylinders are 5 x 5 inches bore and stroke respectively, of which there are four, working 4-cycle water-cooled. The motor weighs 266 pounds, including a flywheel, and is rated at 40 horsepower. There are many other nice details of design which were necessary to complete the plan, some of which are clearly depicted in the illustrations here afforded.

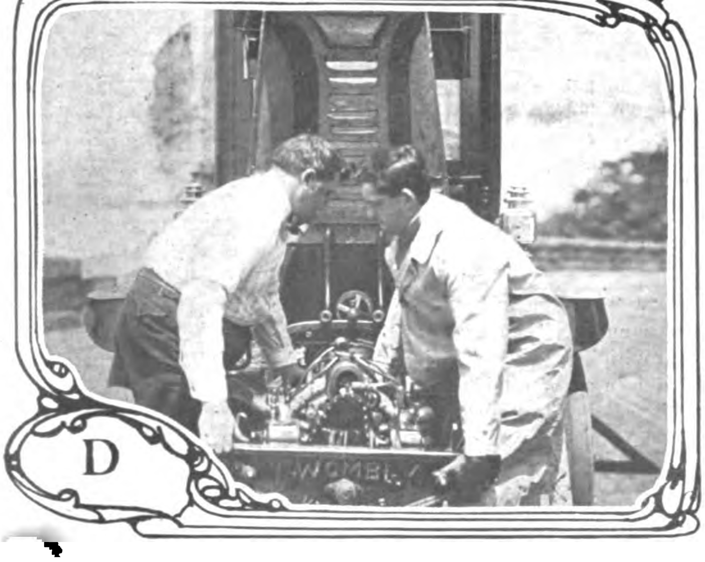


A

B



C



D

DEPICTING AN ENTIRELY NEW IDEA IN AUTOMOBILE DESIGNING WITH A CONVERTIBLE BODY AND A POWER PLANT THAT CAN BE REMOVED AND REPLACED IN THREE MINUTES.

(A) Depicts the motor of the Twombly Car, the same being in cross section showing the opposed cylinders in blackened section of which there are two sets parallel to each other in the horizontal plane. The crankpin C1 has an annular type ball bearing B for each connecting rod and pressure is transmitted from the crankpin C1 to the pressure faces P1 and P2 of the built-up pistons with heads H1 and H2. The built-up piston reciprocates between the pairs of cylinders C2 and C3 in juxtaposition so that to all intents and purposes a single piston serves for two cylinders, and undue pressure from angularity is entirely eliminated in this type of motor. When the crankshaft S rotates, the crankpin C1 describes an arc the radius of which is equal to the stroke of the piston in one direction. The ball bearing B takes the torquing moment, transmits it to the faces of the built-up piston, and since the ball bearing describes an arc equal to that of the connecting rod C1 in addition to reciprocating laterally in the guides, reciprocating motion is transmitted to the built-up piston and it performs precisely as in any other 4-cycle motor. The inlet and exhaust valves are placed one above the other, one valve V1 being shown for the left hand cylinder, and a similar valve V2 is shown for the right hand cylinder. The valves are actuated by cams on the cam shafts C4 and C5; the motion imparted is precisely the same as in a conventional 4-cycle motor. The valves are accessible through the covers C6 and C7 with similar covers in the same vertical plane for the purpose of getting at the valves not here shown. The entire motor is housed in, there being a cover C8 over the valve chamber, and an extension piece E1 between the two pairs of cylinders all around the circumference excepting where the valve housing breaks in. The motor sets horizontally between the two members of the chassis frame, with the cylinders athwartships. The spark plugs are shown S1 and S2 adjacent to the inlet valves, coming to the top of the motor, and the magneto is mounted on the top of the motor in an accessible position with the carbureter just to the back of it.

(B) With the footboards removed, the transmission gear G1 comes into view, it being back of the radiator R1, and the air propeller A1 is also presented. The control system is located amidship with the quadrant Q1 coming up through the floor boards, and the steering gear post P1 is located on the left hand side so that for an enclosed type of body the control system is located conveniently within, and for an open type of body entrance may be had from either side. The ignition system being of the Bosch dual type, the step-up transformer P1 is on the dashboard within the body, coming above the line of the footboards.

(C) This is a view looking at the front of the car with the motor M1 removed and placed on the floor at the left hand side, and the transmission gear G1 also removed and placed on the floor at the right hand side. Referring to the transmission gear, the cone clutch C1 shows plainly with a leather faced cone L1 and a Timken roller bearing R1 which is used for centering and for taking the load as well. Referring to the motor M1, the cross member C2 becomes the front member of the chassis frame and when the motor is slipped back into position in its guides within the side members, the studs S1 and S2 are used for fastening the motor into place, they being the only means for holding the motor in its position, excepting that the cross arms of the motor fit snugly in the guides provided in the chassis frame. The magneto M2 shows on the top of the motor, and the carbureter C2 is in line with the magneto, but to the back of it. At a demonstration which was made at the A. C. A. on August 8 for the benefit of the press, the motor and transmission gear were removed from the chassis and replaced again in 3 minutes and 3 seconds. The motor was running just before the change was made, and it was started again just after it was put back into place. Two men did the work, using nothing but a socket wrench by way of tools. Water and other connections are made automatically and it is the main plan of the company to place at the disposal of users a power plant that can be removed and replaced within a few moments should the occasion require. That is has succeeded in doing so has been proven in the test above referred to.

(D) This illustration of the quick removable power plant was taken while the men were in the act of putting the same back into place. When the plant is slid home, the Timken roller bearing R1 (C) self-centers, and a self-centering means is also provided between the transmission gear and the propeller shaft; at this point a suitable jaw drive is utilized, whereas between the power plant and the transmission gear, the clutch C1 serves as the transmitting member.

(E) The limousine type of body as here shown is complete with the front door, making the same entirely enclosed for inclement weather.

(F) This is a view of the same body with the front door taken away, and the back opened up sufficiently to admit air but protect the occupants from wind and dust.

(G) This view shows the side enclosures for the front ready to go into place. By means of dowel pins the panels are self-centering, and through the good office of an eccentric lock, the panels lock tightly and rattling or squeaking is obviated.

(H) This is a view of the body with the front panels removed, the side and back panels removed also, and the top or deck folded up and over so that it rests on the deck of the front end above the front seats. The most remarkable point, perhaps, in relation to this type of body, is one that cannot be appreciated without examining the same. The joints are all worked out so that there are no inartistic crevices or unsymmetrical surfaces due to the taking away of the panels, or the folding up of the deck. It is also worthy of note that the body is substantially made, goes together without any trouble at all, and runs without squeaking or making noises of any kind.

The Cartercar performed well in the touring division

Brooklyn Dealers' Run

WITH a field of thirty cars in the contesting division, eight among the tourists and with a considerable escort of non-participating automobiles, the two-day Reliability run of the Brooklyn Motor Vehicle Dealers' Association was started early Tuesday morning from in front of the quarters of the Long Island Automobile Club. The sky was overcast and the weather bureau held out promise of a wet trip. But up to the moment of starting, the roads were in fine condition as the result of the showers of the night before.

The course of the run is about 400 miles and it zig-zags across the island, so as to cover most of the picturesque roads. From the start it leads to the north shore at Little Neck and thence through a dozen small towns to Smithtown, where a checking station was arranged. Crossing the island, the tourists made Patchogue and proceeded along the south shore to Bridgehampton, another control. The Eastern point of the tour was Amagansett where the course cuts northward again to the Sound and thence to Southhampton. The second day's run was along the North shore with frequent detours to make up the distance.

The first day's run consisting of 177 miles was accomplished without special incident or accident. The first dozen miles from the start were laid out over poor roads which were succeeded by better going this side of Flushing. Passing through that place the going was bad, but outside the town, smooth highways were encountered almost to Great Neck. A particularly bad stretch at the outskirts of the town, tested the cars and passengers severely and at intervals, trying spots were traversed all the way to Smithtown. The hill roads proved to be in excellent shape and after taking on fuel at Smithtown, the tourists proceeded to Patchogue, the noon control, over typical Long Island highways.

The back track to Smithtown was over another set of good roads and save for some stiff grades near Speonk, the whole afternoon route was easy. All the cars reached Southhampton, the night control, between five and seven o'clock.

Several clean scores were claimed as a result of the first day's run, but nothing official was given out to verify the claims.

One whole section of the run went astray after leaving Bridgehampton owing to lack of confetti, but this will not be charged against the contestants. The start of the final day's run was made from Southhampton at 8 o'clock in the morning.

At the conclusion of the run, clean road scores were claimed by the following cars: 23, Midland; 11, Winton; 14, Hupmobile; 3, Locomobile; 30, Pullman; 5, Ford; 9, Ford; 7, Stevens-Duryea, and 22, Chalmers. Besides these the official report may include similar claims for several of the other contestants.

Tire troubles were experienced by several of the cars, but not sufficient of this variety of trouble was had to affect the final score of any of the entrants. The Halladay, No. 10, broke a valve on the first day's run; Speedwell, No. 19, was ditched during the second day, but was able to continue. Otherwise the run was singularly free from accidents.

Secret controls had been established at five points and the cars were checked at these places as well as the regular checking stations to determine the consistency of their running time. This feature of the affair resulted in some delay in announcing the scores of the various entrants, and it will probably require at least 24 hours to reach exact figures on all the cars.

The weather at the finish was stormy and all the tourists were well soaked when they arrived at the clubhouse of the L. I. A. C. The rain of the final day started about noon and from that time to the end there was gray drizzle that proved uncomfortable to all hands.

Eight beautiful trophies were offered for the winners in the various classes.

MORE THAN TWO-SCORE CARS PARTICIPATED IN THE TWO-DAYS' RELIABILITY CONTEST UP AND DOWN THE LENGTH OF LONG ISLAND

The officials of the affair were: A. R. Pardington, vice-president of the Motor Parkway, referee; E. L. Ferguson, starter and E. F. Korbel, secretary.

The full list of the entrants is as follows:

No. Car	Entrant	Driver
Class 1A, selling at $800 and less—		
14—Hupmobile	D. M. Bellman	A. H. Bellman
15—K-R-I-T	Schaap Auto S. Co.	A. K. Schaap, Jr.
Class 2A, selling from $801 to $1200—		
4—Hudson	Bruns Auto Co.	W. H. Bruns
5—Ford	B. McC. and Bishop	Walter Blake
9—Ford	F. W. Matthews	F. W. Matthews
25—Maxwell	I. C. Kirkham	G. M. Wagner
Class 3A, selling from $1200 to $1600—		
8—Maxwell	I. C. Kirkham	E. T. Bloxham
17—E-M-F	Carpenter Mot. Veh. Co.	F. A. Ainslee
20—Maxwell	W. H. Fessel	W. H. Fessel
26—Crawford	Prospect Pk. So. Garage	W. H. Houdcroft
28—Overland	C. T. Silver	George Weber
Class 4A, selling from $1601 to $2000—		
2—Haynes	J. D. Rourk	L. A. Rourk
6—Inter-State	H. G. Martin	H. G. Martin
12—Auburn	Enterprise Gar. Co.	Jacob Stark
13—Velie	Cumberland Garage	A. Wilmorth
22—Chalmers	Bruns Auto Co.	Emil Feidler
23—Midland	J. M. Boyle	Leo Anderson
24—Haynes	Haynes A. C. of N. Y.	R. Schmidt
27—Herreshoff	A. W. Blanchard	A. W. Blanchard
29—Pullman	Cimmotti Bros.	Ellis Kulp
30—Pullman	Cimmotti Bros.	John Hoffman
Class 5A, selling from $2001 to $3000—		
1—Columbia	I. C. Kirkham	I. C. Kirkham
10—Halladay	Grant Sq. A. Co.	Jos. Kenny
11—Winton	Carlson A. Co.	William Braden
16—S. G. V.	Mears Auto Co.	J. M. Mears
18—Kline	Bryant Mot. Co.	C. Smith
19—Speedwell	G. W. Garland, Jr.	A. Gross
21—Columbia	I. C. Kirkham	J. N. Wagner
Class 6A, selling for $3001 to $4000—		
3—Locomobile	W. H. Kowenhoven	P. Mahony
7—Stevens-Duryea	I. M. Allen Co.	A. J. McDermott

In the division devoted to touring the following cars were entered: Ford, White, Cadillac, Paterson, Stearns, Cartercar, Winton, Stevens-Duryea and a Pullman.

The officials were carried in a Haynes, Franklin, Locomobile and an Acme.

Mathesons in Next 24-Hour Race

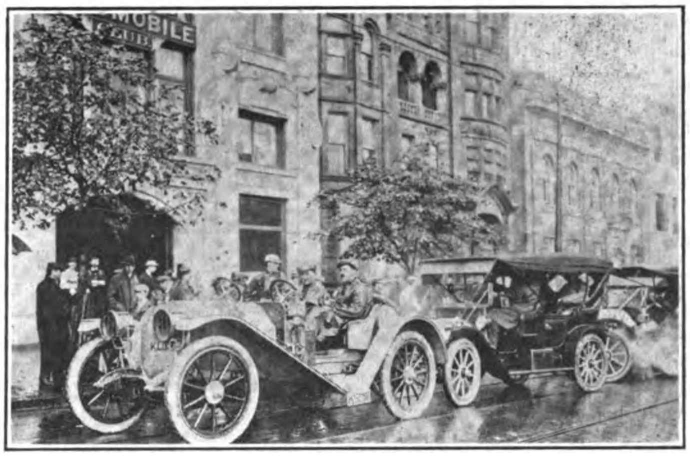
Matheson cars will seen in competition in the next 24-hour race to be held on the Brighton Beach race track under the auspices of the Motor Racing Association of New York, September 16 and 17. In all probability two cars will be entered.

Carriage Builders to Hold Meeting

The thirty-eighth annual meeting of the Carriage Builders' National Association will be held in Cincinnati, Ohio, the week of September 25. In connection with the regular yearly exhibition of carriage parts, wagons and automobiles, there will be a series of business meetings of the association at the Ohio National Guard Armory on Freeman avenue. An elaborate program of entertainment has been prepared.

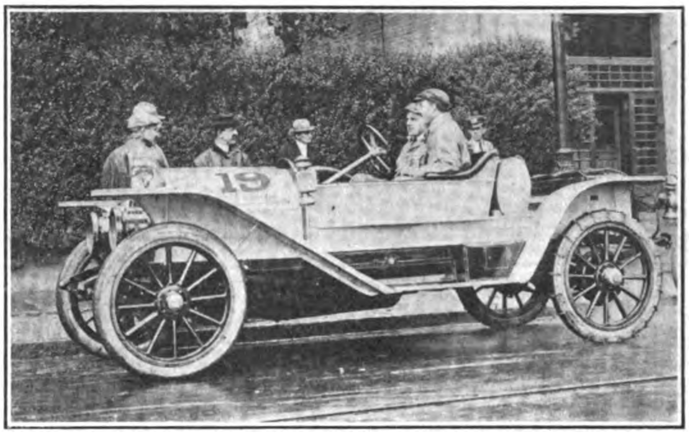
Van Sicklen to Head F-A-L Company

N. H. Van Sicklen, Sr., one of the best known men in the automobile industry, has been chosen president of the F-A-L Motor Company. Mr. Van Sicklen's long experience in motordom and his prominent position in the trade is accepted as a particularly promising evidence of his success as the head of a manufacturing company. His association with the F-A-L Motor Company completes a manufacturing organization of strength and experience.

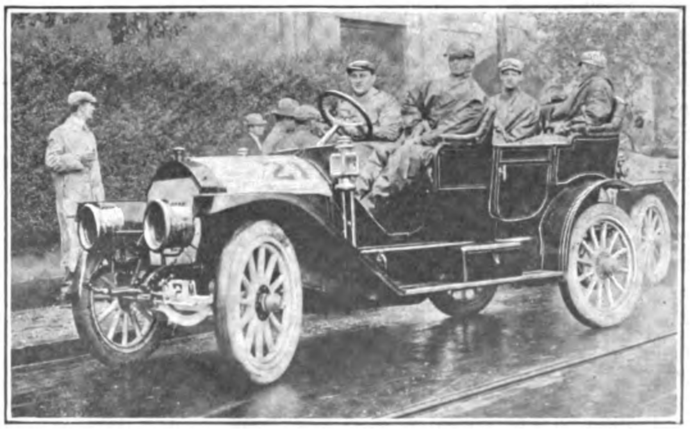


The cars started and finished at the Long Island Club House

Auburn, No. 12, Jacob Stark, driver, gets the word



Speedwell, No. 19, A. Gross in the driver's seat



J. N. Wagner's Columbia, No. 21, a Class 6A entry

Galveston Beach Races

THREE DAYS OF EXCELLENT SPORT FURNISHED TO THOUSANDS OF SPECTATORS. STODDARD-DAYTON AND CHADWICK FEATURED.

GALVESTON, TEX., Aug. 8—Without a hitch, the second annual meeting on the Beach Speedway was run last week in the presence of large crowds of enthusiasts. The feature of the first and second days was the work of Capt. J. W. Munn, president of the Texas State Automobile Association, who drove and won three races in his National 40. The Chadwick captured the 50-mile free-for-all in 42:56 4-5, and established a mile record for the course of 40 3-5 seconds.

The final day of the meet saw a new record hung up for the Beach course in the 200-mile free-for-all, which was won by a Stoddard-Dayton. The summaries:

AUGUST 3

Twenty miles; Class B, Division 2B—

Car	Entrant	Driver	Time
Stoddard-Dayton	Alamo Auto. Co	De Hymel	Did not fin.
Buick	Geo. DeWitt	Dewitt	22:41

M. R. A. to Stage Another Matinee

Several novel features will be introduced at the matinee to be given by the Motor Racing Association at Brighton Beach Saturday. One of the events carded for that occasion is a pursuit race in which the four contestants are to start from the quarter poles, the race to be divided when one of the entrants laps each of his competitors. An attractive program of sprints has been arranged.

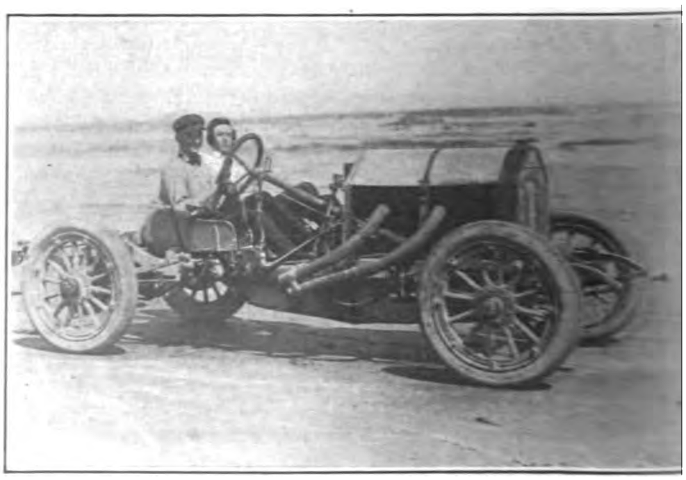
As only four cars can start in such a contest as the pursuit race, the association has announced that it will reserve the right to classify the entrants so as to produce a real contest. In case the entries are of sufficient volume to warrant it there may be two or even more races of this type.

Among the entries so far received are those of a Marion, Cole, S. P. O., Correja, Fiat, Palmer-Singer, Haupt-Rockwell and the probability of still another big car.

One mile time trials against the record of the course, 52 3-5 seconds, will be another feature and considerable promise is held out that the mark will be set lower. It will be recalled that in longer races recently over this course miles have been made over a second faster than the standing record.

In the Class C races, two ten-mile dashes will be run, one for cars of 161-300 cubic inches displacement and the other for 301-600 cubic inches. The amateurs also will have a chance to show their paces. The program will be rounded out with a free-for-all and a one-hour race, similar to the one given recently.

In some respects the program offered for Saturday afternoon is one of the most pretentious of the present season.



Stoddard-Dayton "50" which won the 200-mile race on the Galveston beach in 3 hours, 2 minutes, 22 seconds

Week's Doings in Detroit

NEWS OF TRADE HAPPENINGS DURING THE PAST SEVEN DAYS IN THE GREAT AUTOMOBILE MANUFACTURING CENTER OF THE COUNTRY

DETROIT, Aug. 8—Agents handling the Everitt "30" met here last week in conference with officers of the Metzger Motor Car Company, and spent several days looking over the 1911 line. At the conclusion of the convention it was announced that the distributors in attendance had contracted for 4,000 cars, the entire output of the factory for 1911.

W. S. Piggins is the new president of the K-R-I-T Motor Car Company, assuming the place made vacant by the retirement of Claude S. Briggs. Kenneth Crittenden takes the vice-presidency and B. C. Kaughlin will serve as secretary-treasurer, with J. E. Winney as manager of sales.

Architect Louis Kamper has prepared plans for a factory building for the newly organized Universal Motor Truck Company. The company has purchased a site of three acres in the northeastern section of the city. The building will be of reinforced concrete construction, 254 feet long and 61 feet wide, with a separate power plant. Work will be rushed in the hope of having the factory ready for occupancy November 1. About 500 men will be employed at the start and the company hopes to have its first cars on the market early in February.

It will manufacture commercial trucks of one and one-half and three tons capacity, to be known as the Universal trucks. It is the intention, after the business has become well established, to make a five-ton truck, in addition to the smaller ones. This will make an addition to the plant necessary, but provision has been made for it in the plans. The men principally interested in the new venture are prominent Detroiters for the most part, including C. H. Habercorn, Judge More Rohnert, Louis Kamper, Curt Kling, Edward Barker, Albert Fisher and others. E. Uiklein, of Milwaukee, is another of the incorporators.

Another manufacturing concern is likely to make its début in the near future. As a preliminary step, the Aetna Investment Company was organized last Spring to manufacture a trial car of a new torpedo type. This company has recently increased its capitalization from $5,000 to $20,000. A second corporation, known as the Huron Radiator Company, has been organized by the same people and now has a factory in operation. The officers of the Aetna Investment Company are: President, Malcolm T. Faulkner; vice-president, Dr. L. C. Moore; secretary-treasurer, M. W. Allen. The directors are the officers and John A. Stuart and F. Stephen Kratzett.

The Detroit Auto Specialty Company is building a two-story addition to its plant on Greenwood avenue and has purchased 300 feet of land adjoining its property with a view to further increasing its facilities later on. The company makes gas engines, guards, fenders, tanks and other accessories.

Harold S. Brinker, in his Inter-State "40," which performed well in the Galveston Beach races

The Goodfellow Tire Company, of Detroit, has increased its capital stock from $30,000 to $250,000.

The Lion Motor Sales Company has opened headquarters at 652 Woodward avenue, from which point it will handle the output of Lion cars, made at Adrian, Mich.

Charles F. Garaghty has been appointed assistant to the treasurer of the E-M-F Company, and will also take charge of the repair parts and claims department.

H. A. Mitchell, formerly assistant advertising manager for the Abbott Motor Company, has taken up engineering work with the Hudson Motor Company.

William J. Gaynor, Mayor of New York, Shot

William J. Gaynor, New York's unique mayor, was shot and probably fatally wounded early Tuesday morning by J. J. Gallagher, a discharged employee of the Dock Department. The shooting occurred on the deck of the steamer *Kaiser Wilhelm der Grosse,* upon which Mayor Gaynor had engaged passage to Europe, just prior to the moment of sailing.

Mayor Gaynor, in a Lozier, welcoming the Atlanta-New York Good Roads tourists

Mayor Gaynor, during the few months in which he has been the presiding officer of the metropolis, has taken an important position with regard to good roads and the automobile. He has been alternately in great favor and much blame in the minds of motordom on account of his official activities.

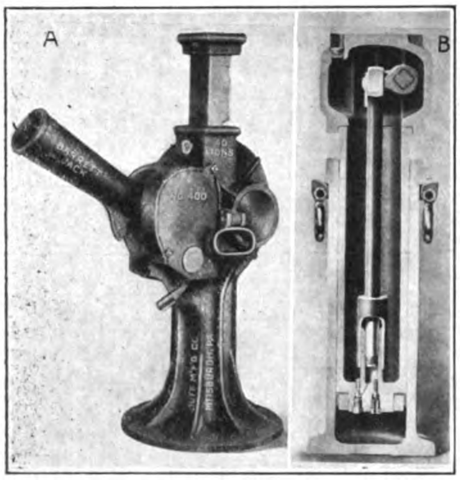
When the legislative matter touching upon the closing of the main automobile course from New York to Coney Island was presented to Mayor Gaynor, he gave the motorists short shrift and a shorter answer; but when the *Herald-Atlanta Journal* good roads tourists reached New York, the Mayor seemed particularly pleased to deliver the address of welcome.

He has been named as an honorary official of numerous contests about New York, but so far as is known he has never served in such capacity. His peculiar personality has made a deep impression upon the people of the whole country, because of his directness and lack of softening diplomacy. The bullet which struck him down took effect below his right ear. The assassin was captured on the spot by "Big" Bill Edwards, Commissioner of Street Cleaning, who was also wounded in the struggle that resulted.

Prominent Automobile Accessories

POWERFUL JACKS FOR AUTOMOBILES

Among the necessaries in the equipment of an automobile tool box is a jack capable of handling the weight of the car without much effort. The Duff Manufacturing Company, of Pittsburg, Pa., is making a specialty of jacks of all sizes, ranging from those suitable for automobile work to large ones with a capacity of 40 tons. The Barrett Ratchet Geared and a sectional view of the Duff-Bethlehem hydraulic jack are here shown. The latter, with its bottom forged integrally, obviates the troublesome problem of packing. A minimum number of parts are employed in the operating mechanism, and any part may be easily replaced without special tools. One man can easily operate this jack to its normal capacity, and no operating valves projecting beyond the body of the jack, there is less likelihood of breaking from rough usage.



Handy jacks for automobile tool boxes

A MODEL QUICK-DEMOUNTABLE RIM

The demountable rim has so proved its convenience and adaptability that it is rapidly approaching the point where it will be included in the regular equipment of all high-class cars.

As quickness of adjustment in the *raison d'être* for the demountable rim, so experts are laboring to still further lessen the time necessary for tire replacements on the road. As a milestone in the progress along these lines the Denegre demountable rim, made by the company of the same name at 1922-24 Avenue F, Birmingham, Ala., is here shown. The illustration shows a steel rim shrunk around the wooden felly of an artillery wheel.

On the inside surface of the tire rim are placed fasteners at equal distances apart. Thirteen are used. These fasteners are 2 inches wide by 2½ inches long and are provided with tongues or ribs ⅝ inch wide. The fasteners taper from the center toward either end and are thus capable of being placed right or left. At the point where the valve extends through the tire rim it is provided with small steel blocks which are cold riveted to the rim. These blocks act as a shoulder by which the rim is pried off. The fasteners are also cold riveted to the rim.

On the steel wheel rim at equal distances apart are a corresponding number of fasteners, which are also cold riveted to the rim. They are provided with grooves ⅝ inch wide, which allow the tongues or ribs of the tire rim fasteners to enter. It will thus be seen that the tongue-and-groove principle is used. These fasteners on the felly rim are the same width and length as those on the tire rim. They are tapered differently, however. The taper extends from one end to the other, or the total length of 2½ inches.

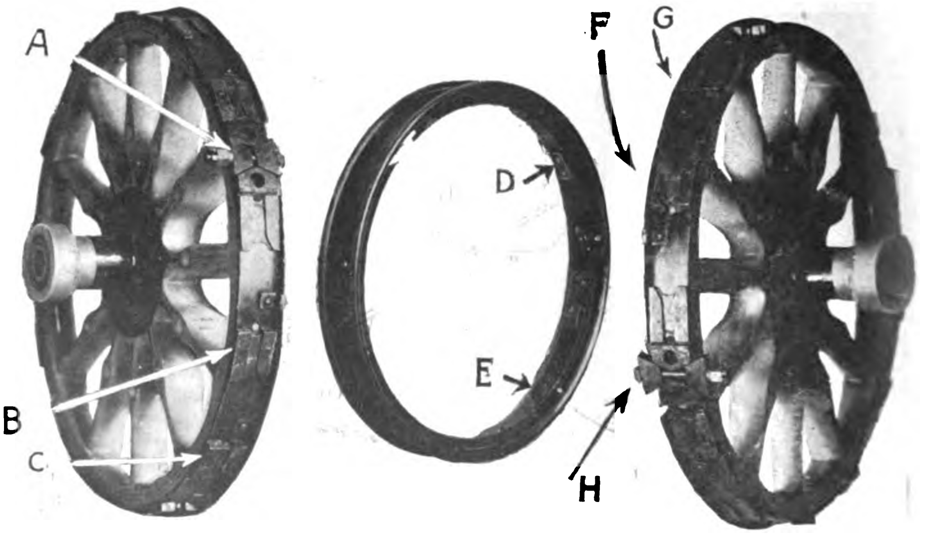
The hole for the valve in the wheel rim and felly is the regulation size, except that it is elongated so as to permit the rotative action when the tire rim is being mounted and fastened. The fasteners are so arranged that the tendency is to tighten by reason of the taper. After the tire rim with the inflated tire has been mounted on the wheel and set into place as much as can be by hand, the key is put in and the final drawing into place is done with the bolt. As but one bolt and nut is necessary, it is an easy matter to have a castle nut with a cotter pin, thus preventing the nut from working off. The felly of the wheel is not cut and weakened by bolts, nor is the tire rim cut through. It is a solid, continuous steel rim. The whole outfit is simple, absolutely safe and reasonably light.

REFINEMENT IN AUTO HORNS

With a view of improving the tone of automobile horns, and especially to avoid the clogging and "muting" common to all horns using the ordinary reed, when the bulb is pressed suddenly or too forcibly, the Gaylor Automatic Stopper Company, of Stamford, Conn., has devised a double-acting reed, which insures a loud blast of the horn under any or all conditions. The tongue, or vibrator, is set exactly central in the reed; this prevents clogging, for one valve is always open and will start the vibration. Besides, the tone produced is smoother and longer with the double-acting, centered reed than with the usual form.

WIND SHIELD WITH GOOD POINTS

The Banker Wind Shield Company has in its No. 2 model De Luxe shield, solved the vexatious problem of producing a clear vision shield with no metal strips across the glass to obstruct the driver's view of the road by using brass channeled shelves which extend from the frame to support the glass. At the same time by the setting of the upper glass fold one-quarter of an inch lower and forward of the lower glass fold, it absolutely prevents any possibility of rain, wind or dust coming through. By the use of adjustable telescoping rods, which are easily operated from the seat, any angle desired may be obtained in connection with ball ratchet hinges. The double fold over the hood is obtained by means of an expander placed inside the telescoping rods, and fitted at the end with a knurled wheel that tightens or releases the tension instantly in raising or lowering the shield. A slight pressure of the hand on any part of the frame will put the shield at any desired angle.



Details of Denegre demountable rim—A, retaining key in closed position; H, the same in open position; B and F, the fasteners; C and G, grooves which take tongues on the tire rim; D, steel fastener, cold riveted to rim; E, showing taper from either end—can be placed right or left

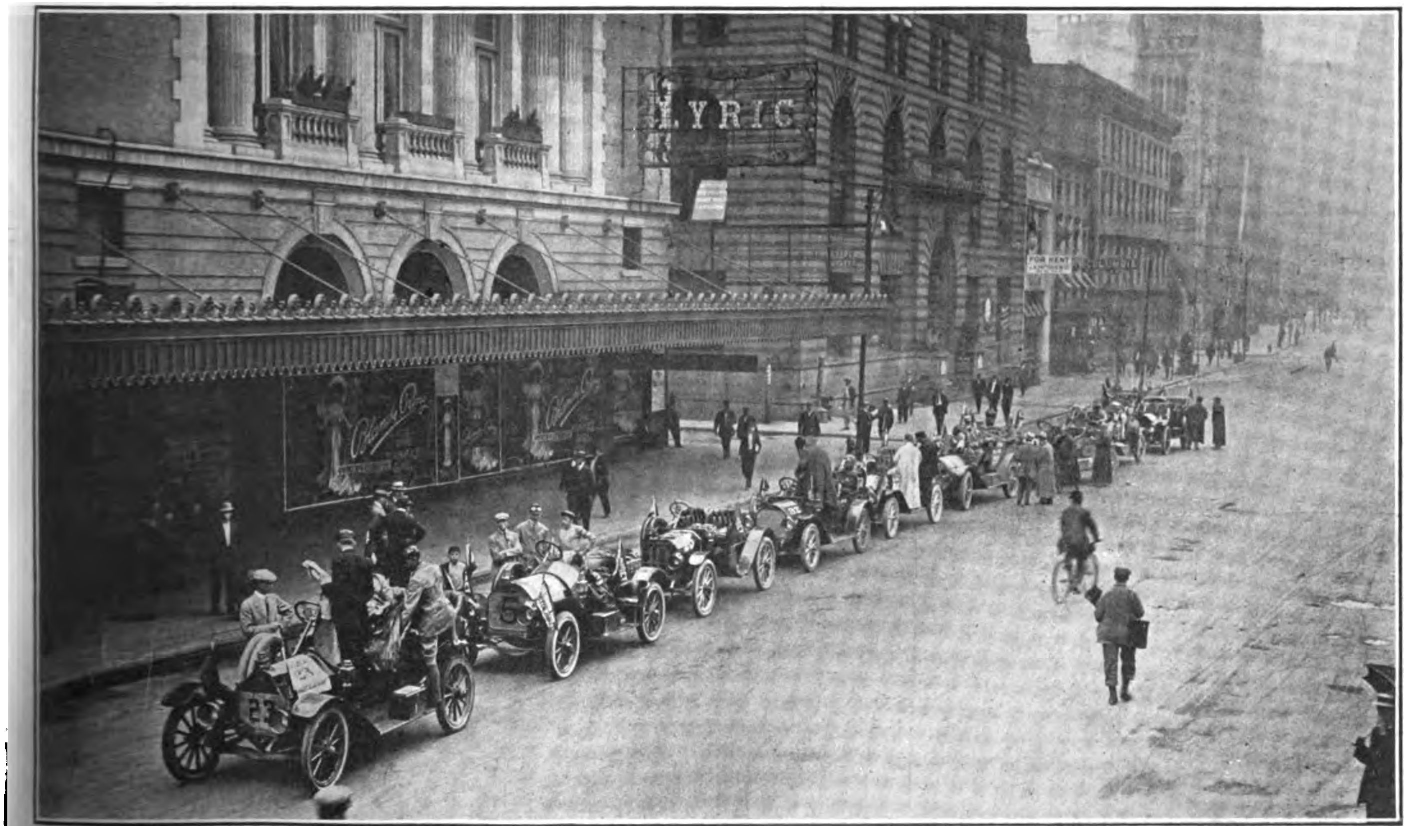
VOL. XXIII NEW YORK—THURSDAY, AUGUST 18, 1910—CHICAGO No. 7

THE AUTOMOBILE

Munsey Tour Starts

MOST IMPORTANT RELIABILITY CONTEST OF THE YEAR OFF ON ITS LONG JOURNEY THROUGH TEN STATES—28 CONTESTANTS AND 8 OFFICIAL CARS IN THE LINE-UP

PHILADELPHIA, Aug. 16—With a typical field of starters in the contesting division, the Munsey Historic Tour of 1910 commenced its long grind of 1,550 miles this morning from Philadelphia. Twenty-three different makes are represented and the cars are running in six divisions under the regular price classification.



THE CARS LINING UP ON NORTH BROAD STREET FOR THEIR 1600-MILE JOURNEY

The route to be followed has been laid out to cover points of historic interest through the scenes of Revolutionary and earlier [illegible] the annals of the United States, as well as touching the great battleground of the Civil War at Gettysburg and some of the places made famous by the conflict of 1812, finishing at Washington on Aug. 27.

The first day's run from Philadelphia to West Point was 160.1 miles, requiring 8 hours running time for the larger cars. The course was over the Old York Road, over which the British troops dashed when Washington met his severe check at the battle of Germantown. Passing through Ogontz, Bustleton, La Trappe and Oxford Valley, the tourists reach Trenton and for a part of the journey follow the path taken by Washington when he surprised the Hessians at Trenton and afterward moved swiftly upon the detachment entrenched at Princeton. From the scene of these two victories for the patriot arms, the course lies along the identical road taken by Washington in reaching Morristown.

A considerable portion of the road going into that place and leaving it was built by the Continental soldiers during the winter that followed the actions at Trenton and Princeton. History says that Washington experienced much trouble in keeping his men busy in winter quarters, and in his wisdom he ordered them to build roads and other strategic and engineering works rather than lie idle and plot mischief. In this way certain sections that were occupied by the Continental forces during the war, received the impetus always given to communities by the possession of good roads.

From that point clear to the New York State line the way lies through a series of roads that antedate the Revolution. Scarcely a mile is passed that does not contain some point of historic interest; either an ancient dwelling that once sheltered the Commander-in-Chief or the site of a block-house or little fort that was the scene of desperate conflict.

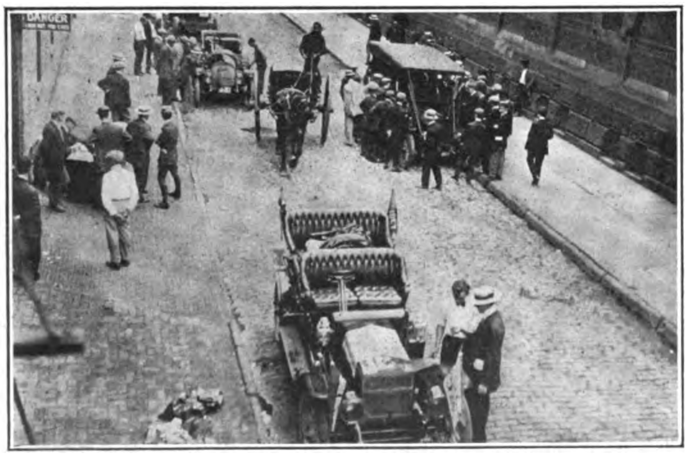
Starter Newmyer, Referee Ferguson, and Hemstreet, Tracy and McMurtry, the "technical" sharps

After entering New York State, the course of the tour is even more interesting for it traverses hallowed ground for much of its distance. Stony Point, where "Mad" Anthony Wayne and his band captured a British stronghold with the bayonet, is one of the features and West Point, once considered the Gibraltar of America and now the seat of the National Military Academy, was the objective point of the day.

The day broke gray and cloudy with prospect of more rain, but the tourists were astir early and sharply at 7 o'clock the first of the cars was sent away.

The officials in charge of the run have been preparing for it for several weeks and as a result every item of detail was carefully arranged in advance. There was no confusion or hurry or tangle and everything moved with the precision of clockwork.

The tour is the second annual of the Munsey newspapers. Last year there was more or less informality about the run; laxity in the administration of the rules and a general tendency to mix pleasure with business to an undue degree. This year, however, the affair is being conducted on a plane with which no fault may be found on that score.



Preliminary inspection of the cars by the Technical Committee

The most searching technical examination was imposed upon the contestants by a committee consisting of E. L. Ferguson, Joseph Tracy and J. A. Hemstreet, which was supervised by Alden L. McMurtry, of the Automobile Club of America. So strict was this examination that three cars failed to qualify and two were allowed to start only after special investigation.

The route to be followed is in no way comparable to that of the recent Glidden Tour. The Munsey Tour runs through a civilized country all the way. There are no such bogs and neglected highways as were found in North Alabama and no such desperate trails as the one that led into Texarkana and through Oklahoma. There are some pretty tough spots in the Munsey itinerary, but nothing like those encountered in the Glidden. Practically from the start to the finish, the tourists will be within hailing distance of populous and prosperous communities in which the automobile already is held in affectionate regard.

Only three 1911 models are in the caravan, although a dozen of the contestants are of almost identical patterns with the models for the coming year so far announced by their manufacturers. The avowed 1911 models are the Crawford, Inter-State and Kline-Kar, all the others being of the current year.

Following a banquet Monday night at the Hotel Walton for those who are participating in the tour, E. L. Ferguson, referee, announced a new system of checking and daily scoring that is intended to do away with much of the annoyance and delay that have been experienced in other runs. The crew of each car is furnished with a book of blank forms containing spaces for car number, division and day. Then follows a skeleton of both morning and afternoon schedules with the starting time, running time, tire time, allowances and time due to arrive at each control. Opposite to these sections is a space for the observer to note the happenings of the day and attached to this blank is the driver's time card, which cross checks against the observer's record. In this card, space is left for the starter to note the time of beginning the run, the rate of the running time, and for the checker to note arrival at controls. Both of these sections must be handed in at the end of each day and obviously must check with one another.

Columbia, No. 2, with G. M. Wagner at the wheel

Mr. Ferguson and the officials hope that an extra degree of promptness can be attained in making up the daily records of penalizations by following this system.

The rule about a car carrying its advertised capacity load has been strictly enforced and those that do not carry as many passengers as might seem to be required have large bags of sand stowed away to make up the legal weight.

The technical examination was decidedly severe. The tread of every machine was measured. The height of the frame from the axle was accurately ascertained. The springs were measured in a most thorough manner, both the width of the leaves and the thickness of the leaves being taken into consideration, and the springs were afterward counted, the whole operation being attended to strictly to make certain that the springs are the springs of the stock certificates and not taken from a heavier model. The distance from the front axle to the end of the front springs was measured to see that the springs do not shift back and forth. Three men were constantly engaged in taking these measurements to check up the makers' certificates.

While this work was going on another man was checking up the spare parts, putting them in bags and sealing them up. Other measurements were also taken. The diameter and length of the spokes were ascertained, and the floor boards and hood covering were removed and an inspection made of the power plant. All the information obtained was carefully jotted down, and the finished page was signed by the driver and the representative of the entrant, so that no dispute could possibly arise.

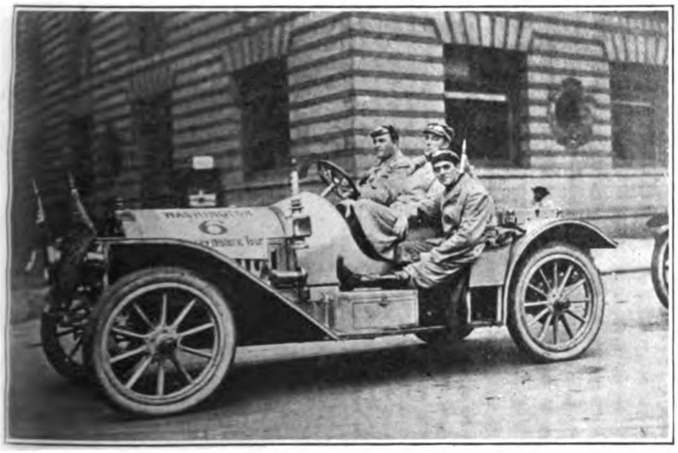
The official cars include the following:

Car	Entrant	Use
Columbia	Columbia Mot. Car Co.	Pacemaker
Thomas	E. R. Thomas M. C. Co.	Press
Washington	Carter Mot. Car Co.	Press
E-M-F	E-M-F Co.	Press
Selden	Selden Mot. Veh. Co.	Pilot
E-M-F	E-M-F Co.	Pilot
Ohio Roadster	Ohio Motor Car Co.	Starter
Brush	Brush Runabout Co.	Photographer

A Randolph truck carries the baggage as a non-contestant.

Under the schedule arranged divisions 4, 5 and 6 must make 20 miles an hour; divisions 2 and 3, 18 miles an hour and division 1 is required to do 16 miles an hour.

The complete list of the officials in charge is as follows: E L. Ferguson, referee; Technical Committee, E. L. Ferguson, Joseph Tracy and J. A. Hemstreet; Arthur G. Newmyer, starter and chief observer; A. J. Irvin, assistant starter and chief observer; Harry Ward, pilot number 1; M. M. Mauger, pilot number 2; J. A. Hemstreet, noon checker; T. C. Willis, checker-in and advance man; Francis J. Byrne, press representative and Olin W. Kennedy, manager for the Munsey newspapers.



One of the Washington pair—W. D. Arrison driving

The day was remarkable for careful driving, every man at the wheel taking no chances for getting points against his machine. Although the pacemaking car was well in advance of the contestants, there was no effort on the part of the cars to pass each other at high speed, every one being content to keep well to his time limit.

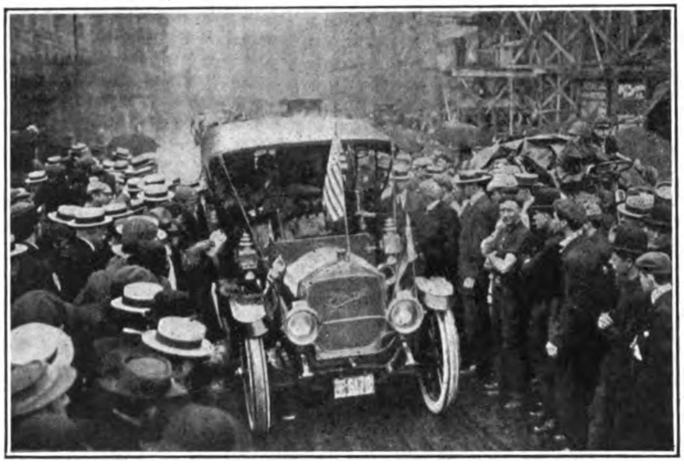
The ferry at West Point, which it was thought would offer some difficulty, was easily manipulated. Arrangements were made to have all the cars ferried over, and this was done before 7 o'clock. Through the kindness of L. Lawson of Garrison, N. Y., a fine place was secured to park the cars in front of the station, but a short walk from the ferry.

The greatest enthusiasm exists among all the men in regard to making perfect scores, all recognizing that a good showing in this tour means glory for their cars.

The scores of the day's run were posted on the official bulletin board at 8 o'clock to-night.

As soon as the data were collected this evening Referee Ferguson summoned the officials of the tour to his room and at once made out the reports so that the men could see them in plenty of time and avoid the irritating delays in posting scores which have marred so many tours.

The observers' assignments for the next day were also given out and the other business of the tour despatched early. This thorough method of handling the official business of the tour on the very first day made an agreeable impression on the contestants.



Last year's winner, Frank Hardart, and his new Elmore

The official cars of the tour maintained their reputation for good work. The E-M-F pilot car carried the confetti men along the route in fine shape. In spite of the fact that the car shifted off the track several times because of bad directions, it was always able to regain the right course and hold its distance well in the lead without ever being sighted by the other machines.

The Selden pilot car did the work for which it was called on flawlessly, covering a score or more of miles more than were scheduled and still scattering confetti well in advance of the contestants.

The Columbia pacemaker car and the Washington and E-M-F press cars carried the newsmen of the trip through the entire journey in speedy time, running back along the route whenever it was necessary and still covering the course with the contesting cars.

The only untoward incident that occurred during the day happened when the Ohio car was midway between Morristown, N. J., and West Point. A passing team became frightened and plunged into the machine which Ross Henwood, the driver, had brought to a standstill. Two women occupants of the carriage were badly frightened, and the carriage was damaged.

Warren-Detroit, No. 10, a candidate for Class 3A honors

The starters' car came up at that moment and drove the women to their home, nearby, afterwards assisting in taking the carriage to a neighboring blacksmith shop. The owner of the carriage refused to accept any money compensation for the injury done.

Every arrangement which had been made for the handling of the contesting cars en route and the performance of official duties has been found to work out well in practice.

The plan to carry a checker along with the pilot car and then to drop him at the noon control so that he could check in the machines has met with general satisfaction and has resulted in carrying on the business of the tour splendidly. The noon checker is picked up by the last press car and brought into the night control.

The Bay State Automobile Club, of Boston, will have several representatives to go over the road to Providence to meet the tourists and escort them to the Hub.

The selection of the Hotel Lenox as headquarters for the tourists is especially pleasing to the Bay Staters for they have just opened their new rooms there and will give the tourists, during their brief stay, the freedom of the place.

The club is especially well located, its rooms being on the Boylston street side and on the ground floor.

The complete itinerary of the tour follows:

August 16 from Philadelphia to West Point, N. Y..........	160.2
August 17 from West Point to New London, Conn............	167.8
August 18 from New London to Boston, Mass.............	117.2
August 19 from Boston to Portland, Me..................	140.8
August 20 from Portland to Bethlehem, N. H.............	122.7
August 21 (Sunday) Lay-over at Bethlehem, N. H.	
August 22 from Bethlehem to Burlington, Vt..............	102.8
August 23 from Burlington to Saratoga, N. Y.............	200.5
August 24 from Saratoga to Binghamton, N. Y.............	164.7
August 25 from Binghamton to Wilkes-Barre, Pa...........	98.5
August 26 from Wilkes-Barre to Harrisburg, Pa...........	115.8
August 27 from Harrisburg to Washington, D. C...........	159.3
Total Mileage	1,550.3

West Point, N. Y., Aug. 16—Under leaden skies the first day's run of the Munsey Historic Tour of 1910 was run off. A severe shower soaked all hands during the morning, but proved not to be of sufficient weight to make the roads muddy. This is due in large part to the fact that the rain fell in a circumscribed area of New Jersey, where the roads are largely made up of stone or well-kept macadam. All day the threat of more rain was impending, but it did not materialize.

The roughest spot in the entire itinerary of the day was a mile within the limits of Philadelphia, where the asphalt pavement had been suffered to deteriorate and was filled with backbreaking chuck-holes. Next to that terrible stretch of street, a hill paved with cobblestones "au naturel," the edges of the living rock, made many of the tourists wonder why they had undertaken the trip. But these difficulties were easily surmounted by all the entered cars, and it was a 30 per cent. grade, twenty miles south of West Point, that caused the most trouble. The Thomas press car, the same machine that made the world-girdling tour some time ago, was the principal sufferer. The car was ditched half-way up the hill and the whole crew consisting of two newspapermen, passenger and driver were shaken up. None of the injuries to the members of the crew proved to be of moment. The car, however, was laid out on the hill all night.

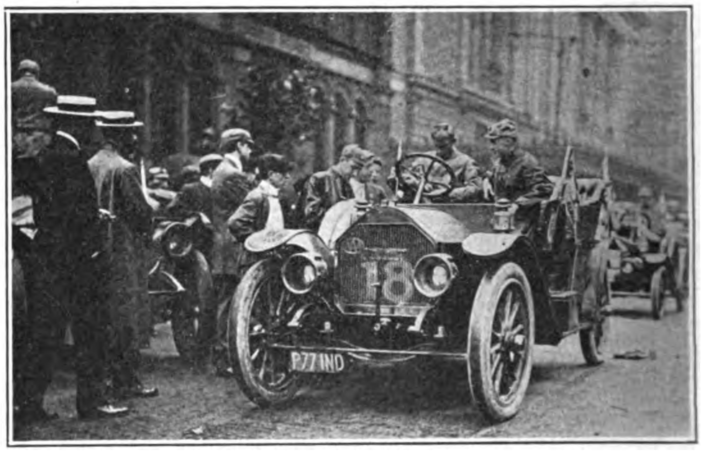
The Inter-State entry was the real sufferer as the result of the day's work as its crew was obliged to put in 46 minutes examining the vitals of the car before it was discovered that a soft steel bolt had been ground up in the transmission and was lodged in the teeth of the gears. I. W. Dill, driver, intimated broadly that the presence of the soft steel bolt was entirely unknown to him and stated that he believed it was put where it would do damage by some malicious person.

Aside from these incidents the day proved an excellent test for both cars and crews.

Arriving at West Point, the tourists witnessed a dress parade of the cadet corps before dinner.

The new scoring plan of Referee Ferguson demonstrated its merit and the complete technical and road showing of all contestants was announced early in the evening.

Only two out of the twenty-eight starters suffered penalties on account of the first day's run. These were Brush Runabout, No. 13, which received three demerits for an involuntary motor stop, and Inter-State, No. 29, which was penalized 46 points for 46 minutes' work in discovering the broken bolt in the transmission and the further penalty of 3 points for taking on lubricating oil out of control—a grand total of 49 demerits for the day.



Great Western, No. 18—C. LaMar—a 3A entry that looks good

The eight-mile-an-hour speed regulation of the military reservation resulted in the arrest of the crew of the pacemaking E-M-F car. The crew of the Corbin were also given a warning. The E-M-F car was summarily banished from the reservation.

The Munsey Historic Tour of 1910 is the second annual automobile reliability event of national importance promoted under the auspices of the Munsey papers—The Washington *Times*, the

Regal Plugger, Class 3A, driven by A. W. LaRoche

Louis Strang and the Pierce-Racine, out for the Class 4A trophy

K. Crittenden's K-R-I-T, contesting for the small car emblem

Ohio, No. 21, looked upon as a possibility for Class 4A prize

Baltimore *News*, the *Evening Times* of Philadelphia and the Boston *Journal*. The Munsey Tour of 1909 from Washington to Boston and return was eminently successful. This year's route is longer than that of 1909, covering 1,550.3 miles. Starting from Philadelphia the course runs to West Point, N. Y., New London, Conn., Boston, Mass., Portsmouth, N. H., and Portland, Me., then through the White Mountains and Green Mountains to Burlington, Vt., and to the Isle La Motte in the upper reaches of Lake Champlain. The course from there is through Plattsburg, Saratoga, Binghamton, Wilkes-Barre, Gettysburg, Frederick and Baltimore, ending in Washington at the office of the Washington *Times*.

Glide, No. 28, Fred Cassel driving, a strong Class 5A probability

Twenty Clean Scores in Brooklyn Dealers' Run

Official announcement of the road work performed by the cars that competed in the two-day reliability contest of the Brooklyn Motor Vehicle Dealers' Association last week was made Saturday by Referee A. R. Pardington. Twenty out of the thirty cars that started finished with perfect scores, as follows:

No. Car	Driver
1—Columbia	I. C. Kirkham
2—Haynes	L. A. Rourk
3—Locomobile	P. Mahoney
4—Hudson	W. H. A. Bruns
6—Inter-State	H. G. Martin
7—Stevens-Duryea	P. J. McDermott
8—Maxwell	E. T. Bloxham
11—Winton	William Braden
12—Auburn	Jacob Stark
16—S. G. V.	J. W. Mears
17—E-M-F	F. A. Ainslee
18—Kline	C. Smith
19—Speedwell	Arthur Gross
21—Columbia	G. M. Wagner
22—Chalmers "30"	Emil Fiedler
23—Midland	Leo Anderson
24—Haynes	R. Smidt
25—Maxwell	C. Fleming
26—Crawford	W. J. Houldcroft
30—Pullman	Ellis Kulp

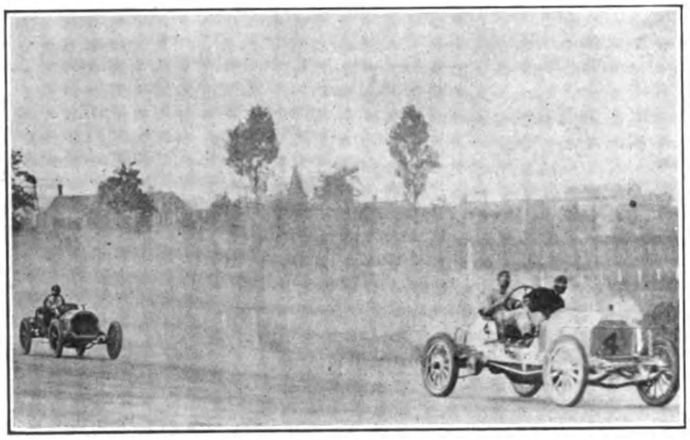
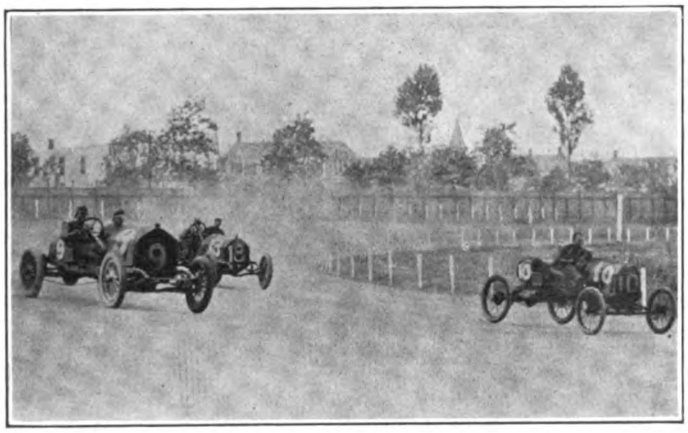
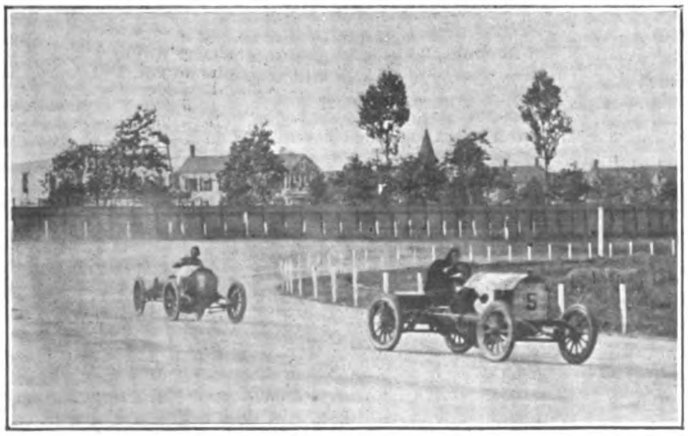
Marion and Stearns passing the Cole "30"



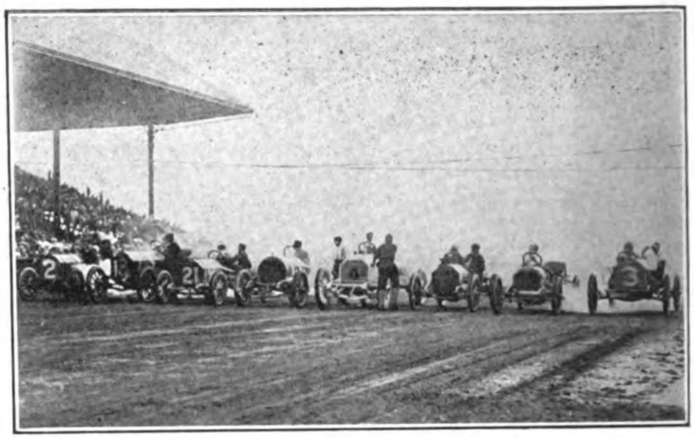
S. P. O. No. 17 overtaking the Stearns



National and Palmer-Singer chasing the Ford



Simplex beat the Fiat in both heats of the match race



Line-up for the hour race, won by the S. P. O.

Brighton Races

S. P. O. AND FORD FEATURES OF A FINE AFTERNOON'S SPORT

FOUR new track records were hung up Saturday at the racing matinée of the Motor Racing Association at Brighton Beach track. The hour mark was set at 59 miles by S. P. O. car No. 20. while the Fiat No. 1 lowered the track record for the mile to 52.26; the five-mile to 4:36.60, and the ten-mile to 9.31.51.

The Simplex "90" administered another beating to the Fiat "60," winning two straight heats after fierce struggles.

The hour race went to the S. P. O. No. 20, which covered 59 miles, the Rainier, No. 15, beating out another S. P. O., No. 17, for the place.

H. M. Swetland acted as referee, while the judges were: J. A. Clark, J. C. Nichols, L. D. Rockwell and George C. John. A crowd of full 10,000 was present. The summaries:

	Car	Entrant	Driver	Time
One-Mile Time Trials				
5	Simplex	Simplex Auto Co.	Robertson	52.71
1	Fiat	Fiat Auto Co.	De Palma	54.76
Pursuit Race				
10	Ford	Ford Motor Co.	F. Kulick	3:29 4-5
7	Hupmobile	H. J. Koehler Co.	A. C. Dam	
6	Staver	Short & Wright	Chris White	
Ten Miles, Class C, Divs. 1, 2 and 3 C				
20	S.P.O.	Henry S. Lake	J. Juhasz	10:40.58
14	Mercer	Mercer Auto Co.	E. H. Sherwood	10:48.88
10	Ford	Ford Motor Co.	Kulick	10:49.22
3	Cole "30"	Colt-Stratton Co.	Endicott	
11	Correja	Correja Motor Car Co.	Joe Taylor	
Ten Miles, Class C, Divs. 4 and 5 C				
1	Fiat	Fiat Auto Co.	De Palma	9:31.51
2	Fiat	Fiat Auto Co.	E. H. Parker	
9	National	Poertner M. C. Co.	W. King Smith	
Pursuit Race, Ten Miles				
20	S.P.O.	H. S. Lake	J. Juhasz	10:27.87
11	Correja	Correja Motor Car Co.	Joe Taylor	10:39.57
3	Cole "30"	Colt-Stratton Co.	Endicott	10:48.07
21	Marion	C. E. Reiss	Disbrow	
Special Match Race, Three-Mile Heats, Best Two in Three				
5	Simplex	Simplex Auto Co.	Robertson	Won straight heats
1	Fiat	Fiat Auto Co.	De Palma	
	Time of winner: 2:43.67 and 2:43.41.			
Pursuit Race, Ten Miles				
9	National	Poertner M. C. Co.	Disbrow	9:55.58
19	Midland	J. M. Boyle	Leo Anderson	10:30.68
2	Fiat	Fiat Auto Co.	Parker	
18	Palmer-Singer	P.-S. Mfg. Co.	Wilson	
Five Miles, Free-for-All				
1	Fiat	Fiat Auto Co.	De Palma	4:36.60
9	National	Poertner Auto Co.	Disbrow	5:07.09
10	Ford	Ford Motor Co.	Kiulick	5:22.50
One-Hour Race				
20	S.P.O.	H. S. Lake	J. Juhasz	59 miles
15	Rainier	Rainier M. C. Co.	Wally Owen	56 1-4
17	S.P.O.	M. P. Batts	Batts	56 1-8
18	Palmer-Singer	P. S. Mfg. Co.	Wilson	56
4	Stearns	J. Rutherford	Rutherford	55
3	Cole "30"	Colt-Stratton Co.	Endicott	53
21	Marion	C. E. Reiss	Disbrow	51
2	Fiat	Fiat Auto Co.	Parker	48

Checking out from Market Street Ferry, Camden

Checking in at "the half-way point," Hammonton

69 BUSINESS WAGONS CONTESTED IN NORTH AMERICAN'S Commercial Run

PHILADELPHIA, Aug. 13—Accompanied by an escort of motorcycle policemen, sixty-nine motor trucks of all sizes, powers and types, participated in the *North American's* Motor Commercial Vehicle Run to Atlantic City, which left here yesterday and ended in Camden, N. J., to-day.

The event was as successful as it was unique, and, being the first contest of the kind ever held, attracted a great deal of attention. It was a wholesale demonstration of the remarkable strides that have taken place in methods of transportation. According to the rules governing the contest, each truck was weighed-in, both empty and full, and in order to facilitate matters three weighing-in stations were established in this city and Camden, where the trucks were weighed-in empty on Thursday and then again weighed loaded to capacity on Friday morning, just before their starting time. All sorts and conditions of truck were represented, ranging in capacity from 600 pounds, the smallest, to seven tons. Each truck before starting was allowed only its minimum amount of gasoline in order to propel it to Camden, where each was loaded and where the actual start of the run was made.

The run was in no sense a speed contest, the trucks at all times conforming to the speed rules, the schedule of which was as follows:

GASOLINE

Class A. 1½ tons capacity and less, 15 miles per hour; Class B, 3001 to 5999 pounds, 12 miles per hour; Class C, under four tons, 10 miles per hour; Class C, over four tons, 8 miles per hour.

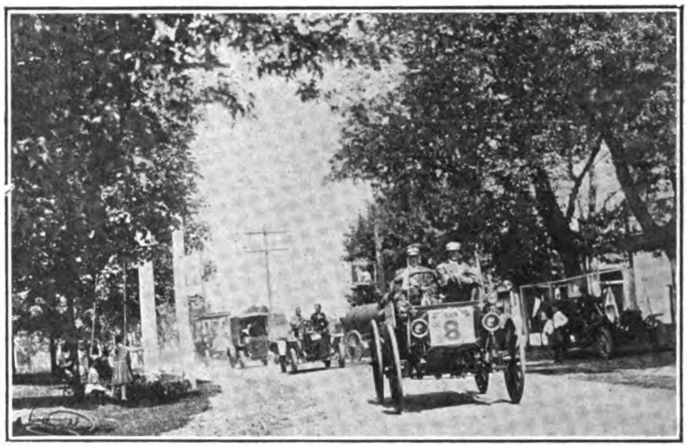
ELECTRIC

Class A. 1½ tons capacity and less, 12 miles per hour; Class B, 3001 to 5999 pounds, 10 miles per hour; Class C, 3 tons and over, 8 miles per hour.

The midway control was established at Hammonton, where each contestant was compelled to make a stop of 15 minutes. Winners of the run will be determined from ability to make time schedule, economy of gasoline, lubricating oil and electric current consumption, and penalties being inflicted for violations of speed rules.

The run down was made by what is called the short route—Camden, Hammonton, Egg Harbor, Absecon, Pleasantville, thence to Park Place, Atlantic City, where the vehicles checked in, right in the heart of the hotel district, and a great crowd gave the contestants a rousing welcome.

Of the 73 original entries but four withdrew, and of the 69 that started 61 completed the entire run. Of the eight that did not finish, five were in Class A and three in Class C. Six of them were from the manufacturers' division and two from the private owners' division.



Passing the White Horse Hotel, Torbensen leading

The big Frayer-Miller checking in at Atlantic City

Reliance, with its big load, reaches the shore

The Autocar had the best representation in line and of twenty cars of this make only one failed to get through. After checking in at Park Place, Atlantic City, the trucks were driven to Young's Million-Dollar Pier, and the exhibition of so many cars of so varied a type attracted a great crowd. Mayor Stoy, of Atlantic City, welcomed the participants last night in Convention Hall.

One of the difficulties feared before the run was held was the effect of the heavily-loaded trucks on the roads, but in spite of the pounding to which the roads were subjected by the weight of the trucks and the tires, some constructed especially for the occasion, no complaints were heard along the route. All of the cars upon their arrival in Camden were found to be in excellent condition.

An unusually large number of press cars accompanied the run, supplied by Automobile Row, consisting of a Welch-Detroit, Premier, Regal, two Buicks, Autocar, Chalmers and Locomobile. The Quaker City Motor Club conducted the event admirably, and, despite the fact that it was an entirely novel affair, everything was carried out with that attention to detail which usually characterizes the Quakers' efforts.

Ten prizes to the amount of $1,000 are to be awarded by the North American, the winners of which will not be announced for several days. Those who had the affair in charge were: Referee, R. E. Ross; starters, G. Hilton Gantert and Joseph L. Keir; chief timer, Paul B. Huyette; members of Quaker City Motor Club's Contest Committee—George M. Graham, Fred. C. Dunlap, A. T. James, A. E. Maltby, Evans Church; chairman of Technical Committee—Charles Stead; judges of weighing-in, Harry C. Volk, Clarence Cranmer, Clyde Woolson; judges, E. K. Leech, Robert M. McCormick, George W. Hipple, H. L. Hornberger, George E. Daniels, H. de B. Keim, J. Archer Paul, E. S. Foljambe, W. C. Jackson, E. H. Lewis.

In reckoning the results, a penalty of 1 point was imposed for every half minute a car was late and awards were based on the ability of cars to make time schedule and for smallest outlay for gasoline, lubricating oil and electric current. The summary:

No.	Car	Entrant	Driver	Time Penalties	Cost per mile per ton
		MANUFACTURERS' DIVISION—Class A (1½ tons capacity and less)			
1	Strenuous Randolph	Randolph Motor Car Company	H. Powers	†	†

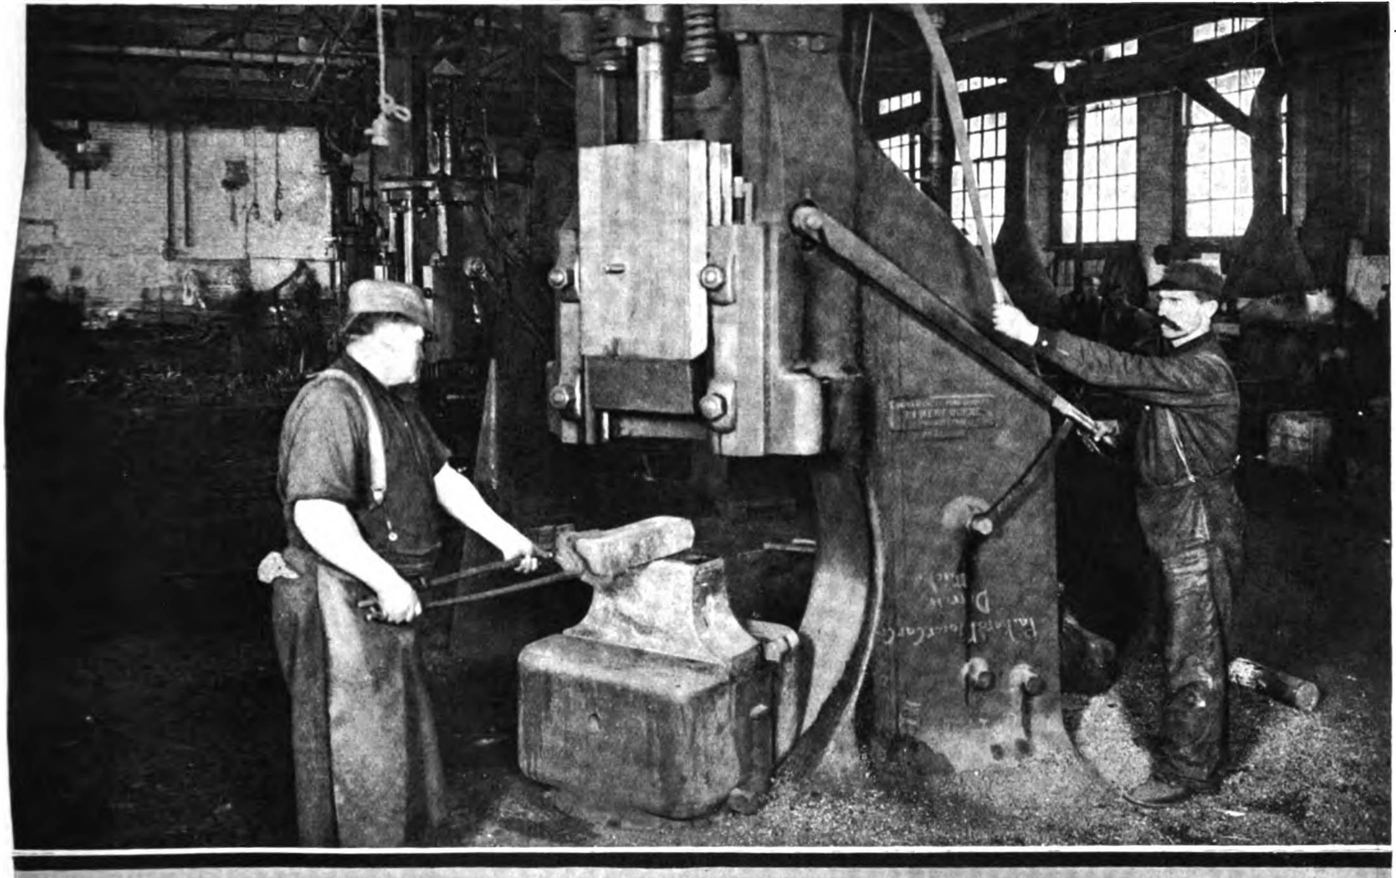
Quality is Induced in the Process of Forging



UNDER THE HAMMER—TAKEN FROM LIFE IN THE PACKARD PLANT AT DETROIT

THAT there is an undercurrent of strength which will sooner or later dominate the engineering side of the automobile situation is apparent to those who penetrate below the commercial level and discover what engineers are thinking about and what the problems are that confront them. When an automobile is completed and the last coat of varnish is applied, it represents crystallized endeavor, but not necessarily an engineer's complete version. Unfortunately, or otherwise, it is not always possible to accept the versions of engineers. The object in building a car is to put it into commercial service, and frequently it is found that the commercial demand is in high discord with the engineer's version. Were the engineer's complete plan to be adopted under conditions as above enumerated, the commercial history of a completed automobile would never be written.

It may seem strange to a casual observer that automobiles are revised year after year. Each new model as it is presented to an indulgent public is represented as embodying all that is good, and the casual observer wonders why there should be any change. This character of observer is like one of the subscribers of THE AUTOMOBILE, who, when requested to renew his subscription, appended a foot-note to the request which read like this: "Kind Friends—Your journal has furnished me all the information I require and I will not be able to subscribe further; so please discontinue." If this subscriber wakes up in two years, and will then look at the automobiles of that time, he will have to ask somebody what they are.

The word "standard" as applied to anything means absolutely nothing, excepting that it conveys the impression that contemporaneous things may be on a certain basis. Evolution is ever going on, and standards shift, due to its onslaught. When an engineer lays out the latest and most approved type of automobile he does the best he can with his light, considering the character of materials available, not forgetting the wants of the supporters of the industry. If the best materials available can be improved upon by fabricators thereof, it stands to reason that the designer will find himself behind progress the very instant that the new materials arrive. If the purchasing public reaches new conclusions the engineer will take the hint.

Each year brings its crop of refinements, and they permeate every phase of the entire situation. In summing up the possibilities for improvement there will scarcely be any chance of disagreement if they take on the phases as follows:

(A) Improvements in manufacturing processes have the effect of (a) reducing the cost of manufacture and (b) making it possible to finish stronger and better materials.

(B) A closer study of designs suggests the possibility of utilizing different methods, multiplying production processes, and taking advantage of automatic means.

(C) Experience on the road enlightens the users who transmit that experience through commercial departments back to the designing office, and attempts are made to incorporate the new ideas.

(D) Stress of circumstances, as a famine of certain kinds of material, introduces new complications, affecting not only the methods of design, but the processes of manufacture as well.

(E) Style has its marked effect. The artistic eye is no more fixed than the standard. As the eye is trained it sees things differently. The result is a change in the appearance of the product.

(F) Legal restrictions are loosened up in time, and designs are changed to conform with the new demands.

(G) Racing and other contests, while they are in a sense sporting events, are in all fairness severe methods of testing, and the capable engineer learns more about the factor of safety than he might otherwise know, with the chance that changes have to be made to bring about unity in the factor of safety as it resides in the several members in order that all the links in the chain will be of the same length.

(H) Locality influences the situation. If a car is produced with the intention that it will best serve in a certain locality, and it proves to be so, the idea will spread, and despite the fact that the car, as produced, is only intended for service in that locality, it will be adopted for other places for no good reason.

With pressure coming from many sources, it would seem as if the time will never arrive when cars will be on a so-called standard basis, nor should there be any complaint on this score. The Navies of the world afford the best illustration of progress along standard lines than anything else ready at hand. The Dreadnought of to-day is probably just as near finality as the 44-gun frigate of the line which was affected by the Navies of the world before even the Monitor was thought of. Each new creation promises to be the best attainable, but those who accept such versions fail to take into account the fact that the promise is invariably advanced by the creator, and that no allowance is made for those who, in the light of all experience, take up the burden with greater vim and advance the work.

Transmission of an Automobile

WHAT K. W. NAJDER, M.E., HAS TO SAY ABOUT A TRANSMISSION GEAR; DEALING WITH IT IN A TECHNICAL WAY

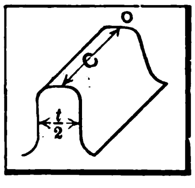


Fig. 1—Diagram of tooth as used in rendering elucidation of formulæ of same

THE speed of a motor may vary between certain limits, and thereby the speed of the car is also affected. Because the power of the motor is directly proportional to the speed, therefore, when the maximum power of the motor is required it must run at its highest velocity. We see that the ratio of the revolutions of the engine to the revolutions of the driving wheels must be capable of variation.

To design a transmission for an automobile, the following data must be known: (1) Normal speed of the motor in r.p.m. (2) Number of speeds required. (3) Value of these speeds in miles per hour. (4) Diameter of the driving wheels. (5) Horsepower of the motor.

Let: V = velocity of an automobile, 20 miles per hour.
D = diameter of the driving wheels, $2r = 36$ inches.
N = normal speed of the motor, 1,000 r.p.m.
n = number of revolutions of the wheels.
12 HP of motor. Then:

$$n = \frac{V \times 60}{2 r \pi}, \quad V = 20 \text{ miles per hour},$$

As 1 mile = 5280 feet, then $V = \frac{20 \times 5280}{60 \times 60} = 29.3$ ft. per sec.

36 inches = 3 feet, so $n = \frac{29.3 \times 60}{3 \times \pi} = \sim 186$ revolutions.

As the speed of the motor is 1,000 r.p.m., therefore, the transmission must be of ratio $T = \frac{1,000}{186} = \sim 5.3$ or $T = 1:5.3$.

Assuming that the maximum velocity should be 20 miles, and the minimum velocity 5 miles per hour, then the ratio must be:

$$T = \frac{5}{20} = 1:4, \text{ or 250 revolutions.}$$

We must figure the strength of the tooth:

$$\text{Circular pitch } t = \sqrt[3]{\frac{M d \times 2\pi}{\Phi K \times Z}} \text{ (from Hütte).}$$

$$\text{Twisting moment } Md = \frac{63,025 \times HP}{\text{r.p.m}} = \frac{63,025 \times 12}{1,000} = 756 \text{ inch-pounds.}$$

$$\Phi = \frac{b}{t} = 1.2 \text{ for auto transmission gears.}$$

Z_1 = 16 teeth on the first gear.
K = 1,000 pounds per square inch.

$t = \sqrt[3]{\frac{756 \times 2\pi}{1.2 \times 1000 \times 16}} = \sqrt[3]{\sim 0.24} = 0.62''$, or the thickness of the tooth is $\frac{t}{2} = 0.31'' = \sim 5/16''$, and this corresponds with 6-8 diametral pitch.

The length of tooth is $C = t \times \Phi = 0.62'' \times 1.2'' = 0.744 = \sim 3/4''$.

$$\text{Pitch diameter} = \frac{\text{number of teeth}}{\text{diametral pitch}} = \frac{16}{6} = 2\tfrac{2}{3}''.$$

$$Z_1 \begin{cases} \text{Pitch diameter} = 2\tfrac{2}{3}'' \\ \text{Number of teeth} = 16 \\ \text{Length of tooth } C = \tfrac{3}{4}'' \\ \text{D. P.} = 6-8 \end{cases}$$

The transmission countershaft shall make half revolutions of the motor, or:

$$Z_1 N_1 = Z_2 \frac{N_1}{2} = Z_2 \times N_2.$$

$$N_2 = \frac{N_1}{2} = \frac{1000}{2} = 500 \text{ revolutions.}$$

$$Z_2 = \frac{Z_1 N_1}{N_2} = \frac{16 \times 1000}{500} = 32.$$

$$\text{Pitch diameter} = \frac{32}{6} = 5\tfrac{1}{3}''.$$

$$Z_2 \left\{ \begin{array}{ll} \text{Pitch diameter} & = 5\tfrac{1}{8}'' \\ \text{Number of teeth} & = 32 \\ \text{Length of tooth C} & = \tfrac{3}{4}'' \\ \text{D. P.} & = 6-8 \end{array} \right.$$

We took the maximum velocity 20 miles and the minimum 5 miles per hour. It is suitable to take for the second speed the mediate speed of these two maximum and minimum speeds:

$$V_2 = \frac{20+5}{2} = 12.5 \text{ miles.}$$

$$N = \frac{1000+250}{2} = 625 - 640 \text{ revolutions.}$$

We need for these revolutions following ratio of pair of gear:

$$\frac{Z_4}{Z_3} \times N_2 = N_3.$$

$$\frac{Z_4}{Z_3} \times 500 = 640,\ Z_4 + Z_3 = 48 \text{ teeth.}$$

$$\frac{Z_4}{Z_3} = \frac{640}{500} = \sim \frac{27}{21}, \text{ then } Z_4 = 27;\ Z_3 = 21.$$

$$\text{Pitch diameter } D_3 = \frac{21}{6} = 3\tfrac{1}{2}''.$$

$$\text{Pitch diameter } D_4 = \frac{27}{6} = 4\tfrac{1}{2}''.$$

$$Z_3 \left\{ \begin{array}{ll} \text{Pitch diameter} & = 3\tfrac{1}{2}'' \\ \text{Number of teeth} & = 21 \\ \text{Length of tooth C} & = \tfrac{3}{4}'' \\ \text{D. P.} & = 6-8 \end{array} \right.$$

$$Z_4 \left\{ \begin{array}{ll} \text{Pitch diameter} & = 4\tfrac{1}{2}'' \\ \text{Number of teeth} & = 27 \\ \text{Length of tooth C} & = \tfrac{3}{4}'' \\ \text{D. P.} & = 6-8 \end{array} \right.$$

The minimum velocity is $N_4 = 250$ revolutions.

$$N_4 Z_5 = N_2 Z_6, \text{ or}$$

$$1000 \times Z_5 = 500 \times Z_6, \text{ then } Z_5 + Z_6 = 48 \text{ teeth.}$$

$$\frac{Z_6}{Z_5} = \frac{500}{1000} = \frac{16}{32}, \text{ then } Z_5 = 32;\ Z_6 = 16.$$

$$\text{Pitch diameter } D_5 = \frac{32}{6} = 5\tfrac{1}{3}''$$

$$\text{Pitch diameter } D_6 = \frac{16}{6} = 2\tfrac{2}{3}''$$

$$Z_5 \left\{ \begin{array}{ll} \text{Pitch diameter} & = 5\tfrac{1}{3}'' \\ \text{Number of teeth} & = 32 \\ \text{Length of tooth} & = \tfrac{3}{4}'' \\ \text{D. P.} & = 6-8 \end{array} \right.$$

$$Z_6 \left\{ \begin{array}{ll} \text{Pitch diameter} & = 2\tfrac{2}{3}'' \\ \text{Number of teeth} & = 16 \\ \text{Length of tooth} & = \tfrac{3}{4}'' \\ \text{D. P.} & = 6-8 \end{array} \right.$$

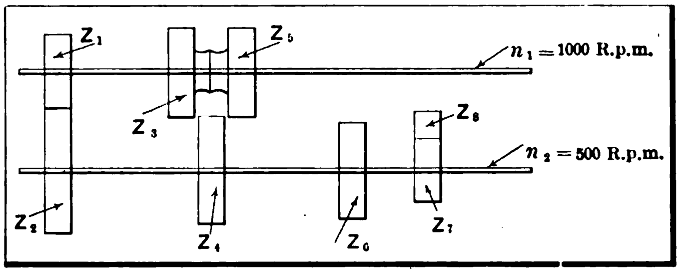

Fig. 2—Sketch showing relation of prime and lay shafts of a sliding gear transmission used in figuring speeds and other relations

We take for reverse 220 revolutions

$$Z_5 + Z_8 = 48 \text{ teeth.}$$

$$Z_8 = 48 - Z_5 = 48 - 32 = 16.$$

$$\text{Pitch diameter} = \frac{16}{6} = 2\tfrac{2}{3}''$$

$$Z_5 \times 220 = Z_8 \times N_8.$$

$$N_8 = \frac{32 \times 220}{16} = 440 \text{ revolutions.}$$

$$Z_7 \times 500 = Z_8 \times 440.$$

$$Z_7 = \frac{Z_8 \times 440}{500} = \frac{16 \times 440}{500} = \sim 14.$$

$$\text{Pitch diameter} = \frac{14}{6} = 2\tfrac{1}{3}''.$$

$$Z_7 \left\{ \begin{array}{ll} \text{Pitch diameter} & = 2\tfrac{1}{3}'' \\ \text{Number of teeth} & = 14 \\ \text{Length of tooth} & = \tfrac{3}{4}'' \\ \text{D. P.} & = 6-8 \end{array} \right.$$

$$Z_8 \left\{ \begin{array}{ll} \text{Pitch diameter} & = 2\tfrac{2}{3}'' \\ \text{Number of teeth} & = 16 \\ \text{Length of tooth} & = \tfrac{3}{4}'' \\ \text{D. P.} & = 6-8 \end{array} \right.$$

Applying the direct drive we get:

$$N_1 = 1000 \text{ revolutions} = 20 \text{ miles per hour.}$$

Applying the second speed we get:

(Z_3 with Z_4)

$$N_2 = 500 \frac{Z_4}{Z_3} = \frac{500 \times 27}{21} = 650 \text{ revolutions} = \sim 12.5 \text{ miles.}$$

Applying the third speed we get:

(Z_5 with Z_6)

$$N_3 = 500 \frac{Z_6}{Z_5} = \frac{500 \times 16}{32} = 250 \text{ revolutions} = 5 \text{ miles.}$$

Applying the reverse speed we get:

(Z_5 with Z_8)

$$N_4 = 500 \frac{Z_7}{Z_8} \times \frac{Z_8}{Z_5} = 500 \frac{14}{16} \times \frac{16}{32} = \sim 220 \text{ revol.} = 4.4 \text{ miles.}$$

Vulgarized Pyrometry

BY MARIUS C. KRARUP. HOW THE PRACTICAL MAN MAY MEASURE THE HEAT OF STEEL ACCURATELY BY IMPROVED METHODS FOR COLOR COMPARISON

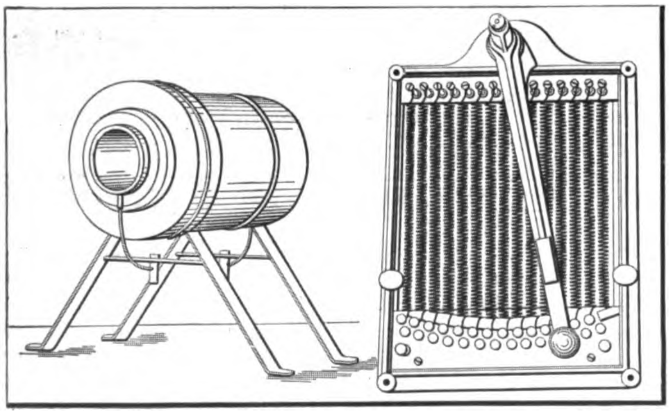
NEARLY every scientific instrument destined for popular uses passes through a stage in its employment at which a certain fondness for its difficulties permits its most obvious practical utility to be obscured. Successively the micrometer, the plotted curve which shows the inwardness of things (when it is not doctored), and the diagrams of the manograph (which dexterously used will prove any theory to be right or wrong), have passed from the scientific stage into daily life and work, and now the pyrometer, the birth companion of special steels, seems to be shedding the fuzzy feathers of the laboratory and donning its overalls.

For a few years it has been pointed out to visitors at ambitious factories as the *pièce de résistance* of the technial manager's intelligent care and discrimination, and in some instances the "temper man" has been induced to believe in its readings almost with as much confidence as he would repose in his own eyesight and native judgment of heat colors. But this is far from saying that he would ordinarily consult it when work was brisk and unobserved or would exercise spontaneous zeal to see that the heat at the hot couple and the heat in the work were alike. It was a nice, instructive pet, however, abundantly fruitful in hot, persuasive terms of more than one syllable. With its catalytic, platinogene metals and the eccentricities of recalescence humps for Ar 1, 2 and 3, it was a dear little storehouse for Latin and Greek derivatives and reflected real dignity on the shop and the calling; and it could very properly, if needs be, charged to the advertising department, which carries all those other overhead expenses for which no one wishes to be responsible.

Finally the pyrometer, by sheer intrinsic merit, is emerging from under the encumbering load of erudition and is proving its ability to pay real money for board and lodging. The recent discourse on its evolution and possibilities at the meeting of automobile engineers at Detroit and the subsequent articles in this journal on the same subject have excellently defined its status in the factory and blacksmith shop. It is useful for all and necessary for those who are determined to produce the best from any given set of steel materials, whether the materials be the most expensive or selected on a strictly economical basis. Among the simple and practical methods for using the pyrometer properly one seems to be omitted, however, which the writer would judge to be particularly well adapted for rapid work under all circumstances, for hand and drop forging, for which a pyrometer is now seldom used, and for hardening, tempering, casehardening and annealing in all shops in which the furnaces and ovens cannot be relied upon to give an absolutely uniform heat. As the suggested method has evidently not been tried very widely, there may be drawbacks to it which have escaped the writer's attention, and it is offered with those reservations which should accompany untried propositions.

Among ladies and dry goods men the human faculty for matching colors by sight is as well established as the disappointment which follows attempts at matching colors by memory or description. On the very rapid and spontaneous action of this faculty the proposed method is based. If a sample of steel may be kept heated to the degree which it is desired that the work shall reach for any given process of heat treatment or forging, the comparison of the work with the sample gives immediate ocular evidence as to whether the heat of the work is right. It must be of the same color as the sample. The eye detects at once the slightest shade of difference. It is not even necessary that the sample shall be the same grade or kind of steel as the work. The same heat produces the same color in all steels.

The makers of pyrometers themselves offer the means for always having a sample of steel at hand heated to any desired degree. The diminutive electric furnaces employed in connection with a recording pyrometer for plotting the rescalescence curve of any sample inserted in the crucible, are in some instances arranged so as to have the sample visible and in other cases may be so arranged without difficulty. They are also equipped with a rheostat and may be equipped with a better or more finely graduated one, if necessary; one which will prevent the heat of the sample from rising above any desired degree. And if the current is produced in the shop its regularity may be assured so as to further safeguard the control by rheostat.



One type of Heraeus horizontal electric laboratory furnace, with rheostat

The blacksmith usually has a dark place near at hand if he judges heat color by sight and from experience. In a corresponding place, preferably shaped as a box with one side open, the little electric furnace with the steel sample may be placed and the recording pyrometer should be conveniently near. When the work is to begin, the current is turned on and the rheostat is adjusted to arrest the heat generation at the temperature which is the desired one for the operation in hand, whether this be forging or any other. The foreman may do the adjusting, with the pyrometer-reading for his guide, and may return occasionally to observe that the reading remains unchanged. If more than one temperature is desired to be represented, as for two or more operations or two different steels requiring different temperatures, a corresponding number of electric furnaces may be placed side by side, each with its rheostat, and they may be adjusted from a single pyrometer, successively, though one pyrometer for each furnace gives a better chance for checking the work as it proceeds.

For work with particularly delicate steels, the use of two crucibles, one with a sample at highest permissible heat and another with the lowest permissible heat, would probably be highly advisable and would train the blacksmith to rapid accuracy in the matching of colors.

By comparison, the most elaborate provisions made at present for the use of pyrometers in factories offer no handy method for deciding when the work has cooled too much for proceeding without reheating, while with the method proposed the workman can readily stick the work into the dark box and make an instantaneous comparison with his heat samples.

Evidently the "constant-heat sample"—to coin a brief term for designating the proposed method—cannot replace either the salt bath, where this is employed mainly for securing the uniform penetration of heat into the work or for the rapid heating of the surface, with the core maintained at the finer texture of a more reduced temperature. Neither can it take the place of a pyrometer connected directly with the forge, the casehardening oven or the annealing oven, since it is necessary to protect against overheating in these places, but it may be a matter of development to arrange for employing the same set of pyrometers for all these purposes.

In practice there may be a few other things to look out for. While it is known that electric furnaces on a large scale may be constructed with very satisfactory guarantees for the steady maintenance of the same identical heat and are so built in conjunction with salt bath apparatus of very moderate size, the requirements in this respect are not very strict with regard to those used for ascertaining the critical points in steel, because they are simply run up to a high temperature and the observations of recalescence are made on "the cooling curve," so that no necessity exists for employing a high grade of materials. It seems possible that the steady, prolonged use of the apparatus might develop inequalities from day to day and perhaps during the progress of a day's work, but even so it would seem that, so long as the pyrometer itself remains in working order, and is consulted once in a while, no misleading can result. But in using this method for guidance in the hardening and tempering of high-speed steels, where it would be especially useful, an apparatus which is known to be reliable above 1,000° C. is of course necessary, and, on the other hand, as salt baths are rarely used here for high-speed heats, while quick work is extremely desirable, the "constant-heat sample" may in the end prove itself more necessary and economical for high-speed tool making than in any other field of work.

The accompanying illustration shows a type of the electric furnaces at present used for recalescence research in the laboratory, and statements may doubtless be obtained from the makers of similar devices with regard to the principal points of interest. The feasibility of making a goodly portion of the area of the steel sample visible is one of these points in question, which perhaps suggests the use of hollow rather than solid cylindrical samples. The other relates to exact data on the variations of temperature to which a steel sample is subject under certain normal conditions of current and resistance, such as at two different trials each maintained for a given length of time. From casual observations it seems safe to predict that the range of variations under test will be found sufficiently contracted to afford all needed security, only one question remaining undecided after such test and this having reference to the sensitiveness of the pyrometer and its faithfulness in recording whatever changes in temperature actually take place in the sample; and this uncertainty applies with equal force to every other method for employing pyrometers.

A trial of the "constant heat sample" method is recommended to engineers and shop managers in the belief that its practical development will prove congenial under average labor conditions and a source of both saving and safety in production.

Export Possibilities

EXTRACTS FROM THE REPORTS OF UNITED STATES CONSULS IN VARIOUS PARTS OF THE WORLD SHOW MANY OPPORTUNITIES FOR OUR AUTOMOBILE MAKERS

One of the recent issues of the Daily Consular Reports by the Federal Department of Commerce and Labor contains seven articles from as many countries, all dealing with some phase of the automobile trade. The leading article is by Consul-General George N. West, of Vancouver, B. C., in which he sets forth the need of an adequate establishment in Vancouver for supplying automobile parts for replacements and repairs.

In his report the Consul General says that 250 new American automobiles have been brought into Vancouver this year and that the motor car is of particular value there because of the rapid growth of the city and the heavy demands for quick transportation.

Under the Canadian customs rules, a second-hand car, two or more years old, is required to pay duty only on the actual cost price, while newer cars must pay the same rate as those of current make. This has resulted in a considerable trade in used cars.

He points out the fact that runabouts are growing in popularity on account of the unpaved streets, which are more easily and economically negotiated in a light car than in the heavier types.

"No establishment here carries a full line of parts for repairs to auto cars," says the Consul-General, "and owners have great delay in procuring parts that may be broken."

Consul William J. Pike, of Kiel, Germany, furnishes some interesting figures on the vogue of the automobile in the German Empire. He reports that there are 49,922 automobiles registered in the Empire, and of the 12,934 foreign cars classified, the United States furnished 686. The increase in registration over the preceding period considered was 7,500 cars.

From Malaga, Spain, Consul Edward J. Norton reports that there are only 32 gasoline cars registered in that city. None of these is an American car. Consul Norton says that the field is limited in Malaga; that there are few wealthy persons residing there; that the streets are very narrow and that the regular price of gasoline is 60 cents a gallon. He says that despite these drawbacks, a few low-priced American cars might find a market.

In this connection it may be stated that Thomsen & Co., of Sydney, Australia, have applied for and have accepted the terms of the Cole Motor Car Company for the exclusive selling rights for the Cole in that territory.

Automobiles are curiosities in Venezuela and are unknown even in such a large island as Curaçao. The use of the motor so far has proved rather too much for the average Venezuelan to grasp and it is recounted in the report of Consul Isaac A. Manning, of Maracaibo, that while the need of such motors is quite apparent little effort has been expended in trying to introduce them. He says there is only one good automobile in Caracas, despite the fact that there are hundreds of miles of excellent roads adjacent to the city. In the island of Curaçao there is not a single machine. As to other uses of the motor, he says that recently the owner of several coasting sail vessels sought to augment his equipment by the purchase of a power boat of some size. He received the boat in due course, but owing to the unfamiliarity of the native and resident engineers with the use of gasoline motors, the boat is still lying up, out of commission.

Consul-General Frank D. Hill, at Barcelona, Spain, outlines a great highway project that may be undertaken in Spain in the near future. Mr. Hill states that there are only 3,000 automobiles registered in Spain and that parties of intending tourists have sometimes been warned not to undertake contemplated pleasure trips through the country on account of the uncertainty of getting through and the likelihood of encountering unbridged streams at awkward periods.

He says, however, that the Barcelona Automobile Club, through its president, the Marquis de Marianao, is urging the construction of a circuit highway from Bayonne through Central Spain to Seville, thence following the Mediterranean Coast to the French frontier, touching many of the chief cities of interest in the land. The circuit highway as proposed would be about 1,674 miles long. The initial outlay would only be about $1,500,000 and the annual upkeep in the neighborhood of $300,000. It is proposed to inaugurate the new road when it is finished with a road contest over its full length under the auspices of the Government.

Consul-General Richard Guenther, at Frankfort-on-Main, Germany, outlines the uses of the international certificate, recently adopted at the conference at Paris and endorsed by seven European countries and the United Kingdom.

He says: "An international certificate has been adopted which will only be issued if the cars and the drivers meet the requirements agreed upon. This certificate is in the form of a booklet, on the cover of which and on the first and last pages the certificate is stated in the language of the country where it was issued. On the other pages this text appears in the language of the various countries parties to the agreement, so that the frontier officials can examine the certificate without difficulty. It is also provided that the motor cars in addition to the home number must show a sign denoting their nationality. The present German mode of attaching a sign to the car by the frontier officials is therefore done away with for the traffic between the several countries to the agreement. For marking dangerous places along the roads, special numbers have been agreed upon. This international agreement became effective recently."

An American Consul reports that a European government is contemplating the purchase of quite a number of automobiles, not the armored automobile type for actual fighting purposes, but for transportation and scouting purposes. The Consul states that a high-class American machine would stand a good chance for performent to the extent of several orders, merely for the purposes of trial, and these might lead to a very large order six months hence; consequently, American manufacturers who are interested should take note before it is too late to demonstrate their product and make preparations accordingly. The Bureau of Manufactures can furnish details.

Letters

ANSWERS TO INQUIRIES WHICH WILL THROW SOME LIGHT ON THE COMPLEX RELATIONS OF FUEL AND TIMING, GIVE ADVICE AS TO GEARING A CAR HIGHER, AND DISPENSE OTHER INFORMATION OF A GENERAL CHARACTER WHICH MOTORISTS WILL FIND OF INTEREST

Complex Relations of Fuel and Timing

Editor THE AUTOMOBILE:

[2,352]—Will you please enlighten me through "Letters Interesting, Answered and Discussed" on the following subject which has puzzled me for some time. What is the variable quantity which causes varying explosion pressures and thereby varying engine speeds and power output when the throttle is manipulated? I believe it is accepted that there is an ideal point in the cycle for the explosion to begin and that the spark should be timed with the idea of firing the charge at this point rather than with any thought of controlling the speed of the engine by this means. The variable, then, that I speak of must be some condition of the charge. Now there are only two things that I can think of which would affect the final explosive pressure, either the proportion of air to gasoline in the mixture, or the quantity of the mixture taken into the cylinder. On the latter depends the initial pressure and the compression pressure. Now as there is a certain proportion of air to liquid fuel that the carbureter is supposed to maintain, there is left but one conclusion, namely, that the amount of a mixture (which proportions are constant) taken into the cylinder, varies with the speed and the power output. If this is so, what is the condition of the charge at the beginning of the induction stroke? If it is at atmospheric pressure, what is the pressure at five times the power output or one-fifth the power output? It would seem that the proportions of the mixture being constant the power would be proportional to the volume at any given engine speed, which I suppose is true. This being the case, how is it that the compression of engines, as shown by experiments, is so nearly constant whether the engine is delivering 10 horsepower or 60? I understand that the engine was turning much faster at 60 than at 10 horsepower, possibly six times as fast, which would permit of the same amount of gas per explosion in both cases; but this only leads me to wonder why the engine accelerated to the faster speed when the throttle was opened. Please let me hear from you on this point, explaining exactly the causes which make an engine turning at, say, 300 R.P.M. under load to accelerate to 1,000 R.P.M. or more when the passage between carbureter and cylinder is more fully opened.

Memphis, Tenn. EVERETT D. WOODS.

Time. If the ignition is early some of the force of the expanding gas will be wasted in arresting the motion of the mass. If the ignition is late, the terminal pressure will be relatively high, but the efficiency of the gas performance will be below the normal level. The ignition should be so timed that the ignition line on an indicator card will be substantially straight. There should be no continuation of the ignition, such as would fatten the expansion curve, nor should the ignition swell the compression curve. This entire subject is very thoroughly elucidated in the engineering number of the THE AUTOMOBILE of July 28, under the caption "The Prediction of Efficiency in Internal Combustion Motors," in which Fig. 1 represents an indicator diagram for the Otto cycle; in other words, for an ordinary four-cycle motor, or as it is properly termed, a four-stroke cycle motor, but if we are to be precise, the so-called Otto cycle is really the Beau de Rochas cycle because the inventor of this name discovered the plan before Otto introduced it, the date of discovery being 1862. If the reader will take the pains to examine the article in engineering number above referred to, even though it is somewhat mathematical, enlightenment will follow, since the indicator card, Fig. 1, brings out very clearly the fact that ignition should become effective at the instant of compression and before the beginning of the expansion stroke. Effective ignition, then, must take place while the piston is on the dwell point at the top of the stroke of a vertical motor as used in automobile work. There is no objection to controlling the speed of a motor by varying the timing of the spark, with the proviso, however, that the motor is not permitted to overheat, which will be true if the spark is maintained too far retarded for too long a time. It cannot be claimed that the thermal efficiency will be maintained at its maximum if the spark variation is used for speed regulation, it being the case that this method of regulating is one which is based upon reducing the efficiency of the motor until it is barely capable of doing the work to be done under certain conditions of speed. The correspondent in this case raises a considerable number of questions, and it is doubtless true that thew hole matter might be discussed much more efficaciously were he to confine himself to some one angle of this large problem for the time being. However, the ignition question has at least five proper subdivisions: (a) the efficacy of the sparking mechanism, (b) the timing of the spark, (c) if the mixture is rich, (d) if the mixture is poor, (e) involving the compression.

(a) There are a hundred reasons why the ignition system might fall below the most fitting requirement, and even with a very efficient magneto, there still remains the question of the ability of the spark plug. It has been found by a series of laboratory tests that spark plugs are frequently incapable of interpreting good magnetos; in fact, it is useless to employ a magneto that is capable of delivering a 30,000-volt spark if the spark plug breaks down at 2,000 volts. This condition obtains in practice to some extent, and it is necessary to find out just what the ignition in a given case is capable of, rather than to assure that the ignition equipment is operating in a satisfactory way, then lay all the trouble onto the mixture or timing.

(b) In the timing of the spark, to blindly assume that some angle of advance as measured upon the flywheel should prove to be satisfactory is to court a fallacy. In the first place, the timing depends for its value upon the compression, then upon speed, again upon the lag angle of the coil, finally upon the burning qualities of the mixture. In solving any complex problem it is necessary to eliminate some of the unknown quantities in order to fix values for the others; this is a particular example of a complex nature, and a process of elimination must be utilized before stable values can be arrived at.

(c) In discussing the quality of the mixture, it will be a waste of time to talk about what it will do before an attempt is made to find out what it is composed of. The chief constituents of gasoline are as follows:

CHARACTERISTICS OF CONSTITUENTS OF AUTOMOBILE GASOLINE

Constituent	Specific Gravity	Chemical Composition
Pentane	0.640	$C_5 H_{12}$
Hexane	0.676	$C_6 H_{14}$
Heptane	0.718	$C_7 H_{16}$

Pentane is a mixture of hexane and heptane, the proportions varying with specific gravity. The composition of the product as it is to be had varies considerably, depending upon the source of supply, but if the specific gravity is 0.683 with a boiling point of 154 degrees Fahrenheit, the proportions by weight are a reasonable expectation, as follows:

PROPORTIONS BY WEIGHT OF GASOLINE

Pentane 2 per cent., hexane 80 per cent., heptane 18 per cent., total 100 per cent.

This composition would carry 83.8 per cent. carbon and 16.2 per cent. hydrogen, requiring about 3.5 pounds of air for a theoretically right mixture per pound of the gasoline.

(d) If the mixture is rich, the low limit will be between 3,400 and 4,000 volumes of air to 1 volume of liquid gasoline. At 3,400 volumes of air per volume of liquid gasoline, the mixture is substantially non-burning; at all events, the ignition system would have to be highly efficient to start the burning and the rate of flame travel would be very slow, indeed. For the best result there should be 1 volume of liquid gasoline to about 8,000 volumes of air, and a poor mixture would be made up of 1 volume of gasoline to about 10,000 volumes of air.

It is a reasonable assumption that some results may be realized under the worst conditions between 4,000 and 10,000 volumes of air per volume of liquid gasoline, but it is also plainly evident that the highest efficiency will only be realized when the air is in the ratio of 8,000 volumes to 1, and there are an infinite number of possibilities within the allowable limits which, if given consideration, will adequately account for many of the variations to be noted in every-day practice.

(e) Involving the compression it will be remembered that the amount of air required will have to be increased as the compression is increased for the reason that there must be a greater excess of oxygen present, otherwise the hydro-carbon fuel will not be burned to carbonic acid and water in its entirety due to the fact that the time is so shortened that in the absence of an excess of oxygen some of the hydro-carbon will fail to grab an oxygen mate. But the very fact that increasing compression increases the inflammability of the mixture adds to the efficiency of the process if enough oxygen is present, and, theoretically, the higher the compression the better will be the result, although in practice premature ignition creeps in when the compression approximates 95 pounds per square inch absolute pressure, beyond which it is not feasible to go under the conditions which govern a four-cycle motor in automobile practice.

Some of the Facts Are Slightly Deranged

Editor THE AUTOMOBILE:

[2,353]—Please answer the following questions in "Letters Interesting, Answered and Discussed."

1. Why should not friction transmission of the simple disc type be on the high gear as well as the car with any other transmission?

2. Why should manufacturers equip their cars with a dual ignition when there are some makers of magnetos who guarantee their magnetos to start any engine of any size and horsepower on a quarter turn of the crank without the use of batteries?

3. Which do you think it would pay a prospective purchaser to buy, a car equipped with solid or pneumatic tires?

4. Will an air-cooled motor stand as much hard usage and last as long as a water-cooled motor?

5. Why can some manufacturers build six-cylinder, 50-horsepower cars and sell them for $2,000 when other manufacturers ask from $1,000 to $2,000 more for the same style car, made of the same grade of material, or is it true that the material is the same?

Palm, Ala. R. F. HENRY, JR.

1. Some cars are built that way.
2. Habit.
3. Pneumatic tires.
4. Yes.
5. Do they?

Rather Pointed Questions About Important Matters

Editor THE AUTOMOBILE:

[2,354]—Will you please answer the following inquiries:

1. In turning a curve, which of the two hind wheels pulls the most, and why is the propelling power lessened?

2. Will more or less gasoline be consumed by running under the same conditions for a certain distance at the rates of, say, 15 and 40 miles per hour?

3. When will the Selden patents now in force expire?

4. Is there any relation between the horsepower used by a horse in pulling a machine and the same power applied by the engine in self-propelling?

5. Is the impact on a pneumatic tire under a certain pressure, against an obstacle, required to be greater than the pressure in pounds per square inch before the pressure in the tube will be raised? In other words, will a loaded car show greater pressure on the tires than when the wheels are jacked up?

Rome, Ga. R. M. H.

1. The outer wheel. The reason for this lies in the fact that it presses on the roadbed with greater force. The reason it presses on the roadbed with greater force is because it serves as the fulcrum when the car tends to turn over, and the inner wheel tends to leave the ground. The propelling power may not be less. If the speed of the car is not reduced it is self-evident that it takes more power to maintain that speed on a curve than it would on a tangent (straight line).

2. Power is required by a car on an increasing basis as the speed is increased. Just what the increase in power will be depends upon the condition of the roadbed, shape of the car, wind resistance, etc. In view of the variable nature of the problem, it is not possible to definitely state just what the increasing power will be unless definite measures are taken in the process of finding out. It is certain, in any event, that the power required to go a certain distance at 15 miles per hour will be less than the power required to go the same distance at 40 miles per hour.

3. The Selden patent is No. 549,160 and was taken out November 5, 1895. The life of a patent is 16 years. There is a chance that this patent may be given a new lease of life; if so, it will run for 16 years more.

4. One horsepower is equal to the force of 33,000 pounds lifted 1 foot in 1 minute, or the equivalent. It makes no difference how the effort is made, whether it be by a horse or an automobile; it is immaterial as to whether the weight is lifted 1 foot in 1 minute or if the reverse holds and the weight falls 1 foot in 1 minute. It will be the same horsepower if 33,000 foot-pounds are expended in 1 minute in drawing a vehicle. It will be the same effort if the vehicle is propelled.

5. Any force that will compress the gas in the tube will raise the pressure in pounds per square inch. When the wheel is jacked up the volume of air in the tire is afforded a certain space, hence a certain pressure will be manifest; but when the wheel is supporting the load, the volume of the air will be reduced, hence the pressure per square inch will increase accordingly.

Looking for Trouble in the Most Direct Way

Editor THE AUTOMOBILE:

[2,355]—I have a 40-horsepower shaft-drive motor geared about 3 1-2 to 1. My desire is to gear the car higher, as I want more speed. Could you suggest a proper gearing, and the best way to change the original? The transmission is of the progressive type and no "direct on the high" or third speed.

New York City. ARTHUR J. SHAFER.

The sum of the teeth in each set of gears in the transmission system must be the same. This means that the sum of the teeth of any one set cannot be changed; it will be possible, however, to subtract from one gear as many teeth as are added to another, but it is highly improbable that there is sufficient room in the gearset to allow of increasing the number of teeth in any one of the gears. The bevel-gear set offers small opportunity for the purpose here mentioned for the reason that there may be no room available which will permit of using a large diameter gear, although the bevel pinion could be reduced in size if it has more than 14 teeth as now constituted. In all probability the motor would be overloaded were the ratio changed to give a higher speed to the car. It is also to be remembered that the life of the car will be enormously decreased if its speed is increased. It is well to remember that tire depreciation becomes a serious matter with increasing speed.

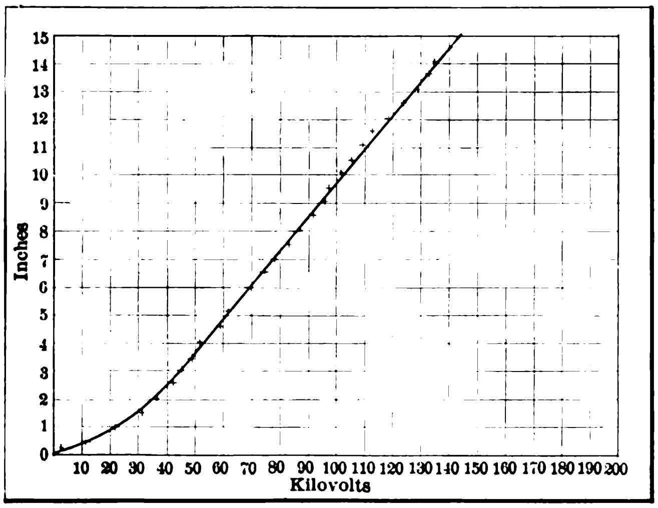
Questions That Arise

FORMULAE FOR SPRINGS; STUB TOOTH GEARS; AUTOMATIC VALVES; SHOCK ABSORBERS; HIGH VOLTAGE MEASUREMENTS; THE FLAMING ARC

[205]—There seems to be a good deal of uncertainty in the minds of users of automobiles as to the legitimate scope and practicability of shock absorbers. Just what is the reasonable expectation with their use, and why do some of them seem to fall short of the requirement?

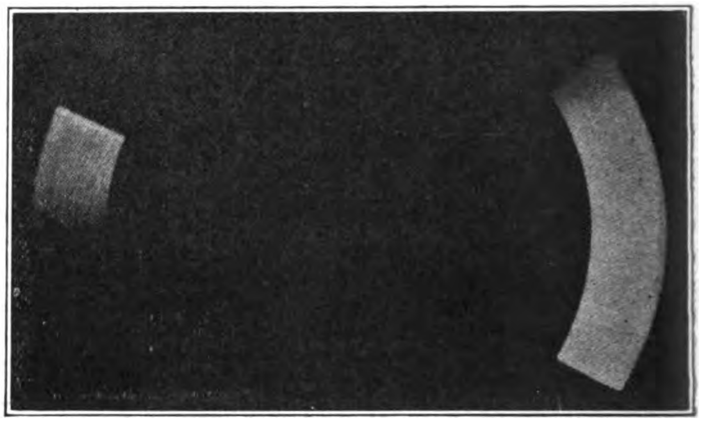
There is absolutely nothing new about the shock-absorber idea; it had its inception when railroad trains were brought into vogue, and the so-called bumper on a freight car would be incomplete without a shock absorber. In freight-car work, where the shock absorber has to contend with strenuous conditions, there are two principles in common use, one of which depends upon the action of a spring, and the other upon friction. Discussing these two principles, it will be readily appreciated that the spring idea takes into account the desirability of gradually absorbing the energy stored in the moving mass. Spring bumpers produce train oscillations, due to the fact that the springs give back, in a reactive sense, the energy stored in them, and enough work is done in the form of oscillations to absorb the energy of impact of the cars as they bump into each other. That the energy must be absorbed before the cars will be brought to rest is self-evident, but a more quiet way of obtaining the desired result is represented in the form of bumper that dissipates the energy through the medium of friction, which is the second principle involved. The friction bumper has no reaction component; all the work is dissipated in the form of heat. As regards the instability of some forms of shock absorbers employed in automobile work, it can only be explained on the ground that the method of utilizing the principle is too frail. If bumpers can be made which will do the work in freight-car practice, involving long trains, surely they can be so contrived that they will serve perfectly in stopping the vertical bounce of the chassis frame and its load as represented in an automobile. The illustration here afforded shows the performance of a friction type of shock absorber under road conditions. The vertical bounce of the chassis frame is represented by the series of irregular lines above and below zero. The zero position is representative of the position of the chassis frame when the car is standing still. The test was made on a 50-horsepower Léon Bollée touring car with an Ellsworth Bumpometer.

[206]—How are high voltages measured in spark coil work? Are there any instruments, as voltmeters, of the conventional sort that will do this work?



Ratio of length of spark gap to voltage in the arc as arrived at in regular alternating current work

When it is desired to measure thousands of volts, conventional forms of instruments fall short of the requirement, and the length of the spark gap is measured instead, from which length, through the use of a calibrating curve, the voltage is estimated. The estimate is of course somewhat inaccurate, but the chances are that the error is within 2 or 3 per cent. The curve here given will suffice to illustrate the idea. In this curve the abscissæ read kilovolts (kilo means 1,000, hence thousands of volts) and the ordinates read inches, length of the spark gap as measured in the open air. It will be remembered that the resistance of the gap will increase with the pressure of the gas, and in ignition service on this account allowance must be made for the increased resistance due to the gas in the cylinder. The curve here shown indicates that it takes 20,000 volts to jump a gap substantially 1 inch long. In other experiments it has been found that a spark that will jump a 1-2 inch gap in the open air will barely suffice for a 1-32 inch gap in a spark plug under pressure in the cylinder. It would seem that a 1-2 inch gap in the open air will be broken down under an electromotive force somewhat below 9,000 volts.

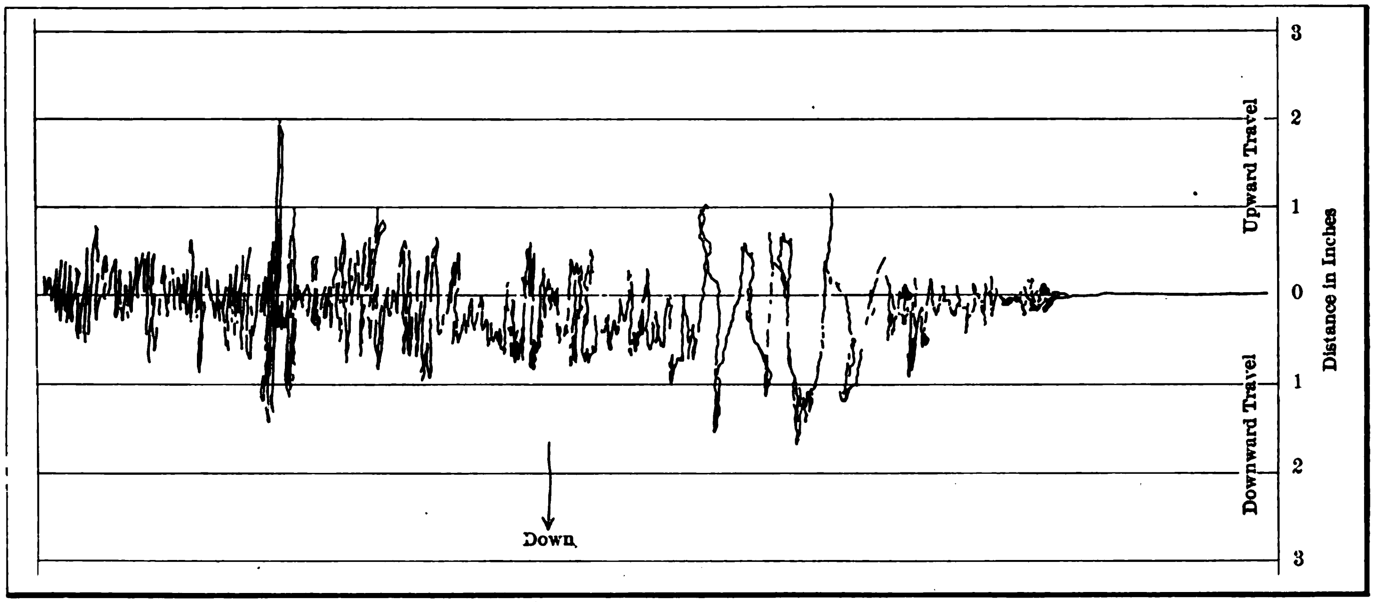


Photograph of spark from a Bosch magneto used to illustrate the text descriptive of what is designated as the "flaming arc"

[207]—What is the meaning of the designation "flaming arc" as applied to a magneto?

When an ordinary spark coil is used, the energy dissipated in the spark-plug gap is limited to that which is represented by the voltage at the instant of breakdown multiplied by the current in amperes. The spark coil is a transformer of electrical energy rather than a generator thereof. In view of this fact no energy can be expected from the spark coil, excepting that which is represented at the instant of breakdown. The so-called "flaming arc" is present when the energy is delivered by a high-tension winding in connection with the armature winding on the armature of a magneto. The high-tension winding does all that a spark coil can do in that the electromotive force impressed thereon is sufficient to disrupt the gap in the spark plug, but since the magneto is a generator as well as serving in the capacity of a transformer there is a follow-up current supporting the initial discharge, which produced the so-called "flaming arc." The situation is adequately depicted in the illustration here afforded, which was made by photographic methods, utilizing a Bosch high-tension magneto in the process.

[208]—Is it not true that a great many spring breakages occur in even the better class of automobiles, and does this not indicate that there is a lack of appreciation of



Record taken from an Ellsworth bumpometer showing the vertical bounce of a 50-horsepower Bollée car on ordinary New Jersey roads representing an average condition

the desired qualities in springs for this service? Does the fault lie in poor material, or are the methods of design so complex that spring makers are incapable of putting them into practice?

There is a fundamental reason why the best obtainable material for spring suspensions is worked to the limit of its ability, and is likely to fail in service in the course of time, although the evil day should be deferred. Take the half-elliptic type of spring suspension, for illustration; the best result comes if the span of the spring in each case is long, but the extreme fiber strain must be a near approach to the elastic limit of the material. No spring of this type will give the desired easy riding qualities unless the material is worked at a high stress. If there is too much material in the spring and the extreme fiber strain is low, the action will be soft, and the spring will fail to respond to the induced oscillations due to road inequalities. There are two points of view for the designer, one of which is independent of the formulæ as here given, i. e., the life of the spring will be long or short depending upon the quality of material used in the spring, independent of the quantity required as indicated by the formulæ. In other words, the foot-pounds of work that should be put upon the material on a basis of safety must be limited. It is very likely that a safe basis is inside of five foot-pounds per pound of material used. The formula as follows is in the simplified form, and will suffice for a spring maker of competence. It will be of small value, however, to a novice.

In the designing of semi-elliptic springs, while it is true that there must be a certain mass of material to properly do the work no matter what the conclusion may be from the formula point of view, the fact remains that an approximation of the true size will help in the process, such as the following: Let,

S = span or distance in inches between the eyes at the extremities of the spring;

B = breadth of the spring-plates in inches;

t = thickness of the plates in 1-16 inch units;

N = number of the plates in the make-up of the spring;

W = load in tons of 2,000 pounds on the spring;

k = a constant depending upon the character of material used. When,

$$N = \frac{WSk}{Bt^2}$$

The value of k is 11 for ordinary work; it should be lowered somewhat if the springs are to be more perfect; it may be increased a little if the character of the material used in the spring-plates is on a high plane; care should be exercised in any process which adds to the burden of the material.

It is frequently desired to check back with a view to determining the deflection in inches, per ton of load, considering a given spring. A formula that is regarded as comprehensive for this purpose is written as follows: Let,

D = Deflection in inches per ton of load, S, B, t, N, represent values as before

When,

$$D = \frac{S^3}{k\,B\,t^3\,N}$$

The employment of a capable formula is really a small detail in the manufacture of springs. The question of material is of the utmost importance. The better the material the more quickly it will be spoiled in a poorly equipped plant, or if it is manipulated unscientifically. The best results come if the methods for heat treatment are adequate for the needs, assuming that a pyrometer takes the place of "rule-of-thumb" methods which formerly obtained in the manufacture of carriage springs. But a pyrometer may be the source of much trouble if it is not handled in accord with its characteristics. The readings taken from a pyrometer will be absolutely wrong if the cold end is not maintained at a constant temperature; preferably the temperature should be 0 degree centigrade, unless the pyrometer is calibrated at some other fixed temperature that can be maintained more readily.

[209].—Why were motors formerly built with automatic valves instead of valves with a positive action?

In the early days of motor building, due to mechanical imperfections, the speed was relatively low, and automatic inlet valves work best at low speeds. When it was found desirable to operate motors at higher speeds, trouble was experienced with automatic valves, and with the perfection of positive valve motions, more power was realized, and the uncertainties which always attended automatic valves, together with the fact that they stood in the way of more power, led to their final abandonment.

[210].—What is the advantage of a stub tooth gear?

The tooth of a gear is related to a cantilever beam so that the longer it is the greater will be the fiber strain at the fixed end of the beam. Since the ability of a gear depends upon the strength of the material up to its limit, and limiting fiber strain for the rest, it is safe to conclude that a short tooth will offer the greatest resistance and is desirable from that point of view. As a general rule, the Brown & Sharpe shape of involute tooth offers so many attractions that it is accepted as satisfactory, and there is a certain advantage present in maintaining a standard unless some serious objection is brought against the same.

The Pyrometer

ITS DEVELOPMENT AND USE. BEING THE THIRD INSTALLMENT OF AN ARTICLE BY WM. H. BRISTOL READ BEFORE THE SOCIETY OF AUTOMOBILE ENGINEERS AT ITS SUMMER MEETING

In Fig. 10 a complete portable outfit is illustrated with the fire end, leads and portable instrument.

In Fig. 11 an indicating instrument is illustrated with an extra compartment containing a rotary switch. Several sets of leads and fire ends may be connected to the different points of the switch so that by turning the handle the operator can throw into circuit the fire end of any of the different furnaces, and instantly the instrument will respond, giving an indication of the temperature in the furnace to which it is connected.

The diagram Fig. 12 shows a recording instrument arranged in combination with three independent indicating instruments, each connected to its own independent fire end for three different furnaces. The indicating instruments can be located at convenient points for the observation of the operator, while the recorder may be located in the superintendent's office at a distance, and by means of switches he can connect the recorder to any one of the different furnaces, the operator having no knowledge of which furnace is switched on to the recorder. The moral influence upon the operator of the furnaces with a single recorder is in some cases almost as valuable as if there were three recorders.

The electromotive force developed by the base metal thermocouple, even though it is a great deal more powerful than that produced by the platinum-rhodium couple, is insufficient to operate the recording arm resting continuously on a moving chart. Several different designs for overcoming the friction between the moving arm of the galvanometer and the chart upon which the record is traced have been devised. The methods most commonly used in these recorders consist in either pressing the arm periodically against the chart, or vibrating the chart against the arm. The method of vibrating the chart so as to bring it into contact with the arm periodically and leaving it free to move under the influence of the comparatively feeble current between the intervals of vibration has proved very satisfactory.

By semi-transparently smoking the charts it is only necessary to vibrate the chart periodically into contact with the tip of the indicating arm, thus removing a small particle of the lampblack from the chart. The series of marks made by the periodic contact of the recording arm where the carbon is removed from the chart forms a continuous curve.

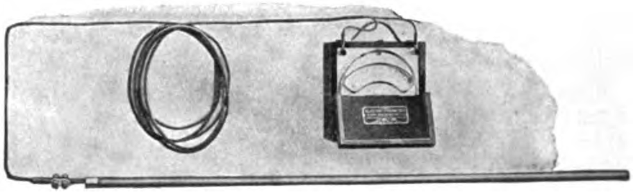


Fig. 10—Complete portable pyrometer outfit

A reduced photographic reproduction of a smoked chart record is shown in Fig. 13, the curves of this chart being made in determining the absorption and recalescent points of different metals.

The smoked surface of the charts is extremely sensitive to the recording arm, and after the record is completed the chart may be removed from the instrument and "fixed" by immersion in a fixative solution. After fixing, the records are permanent and can be filed for further use.

In illustration Fig. 14 an ink type of recording pyrometer is shown. In this instrument an inking pad is located in front of the chart over the arc traversed by the end of the recorder arm. A tiny capillary gold tube open at both ends is carried at the end of the recorder arm. When the chart is periodically vibrated it is pressed against one end of the tube and at the same time the other end of the tube is pressed against the inking pad. A dot of ink is left on the chart and a further supply is simultaneously taken up by the tube from the pad. Between the vibrations of the chart the pen arm is free to move without friction. The periodic vibration results in a continuous record, as the series of dots will form a curve corresponding to the changes of temperatures.

For very open scales the indicating or recording instruments are made with an initial tension upon the indicating or recording arm so that they do not begin to indicate until the working range of the scale is reached. For illustration, a scale can be readily made beginning with 800 deg. Fahr. and ending with 1800 deg. Fahr., and if a large size instrument is used the gradua-

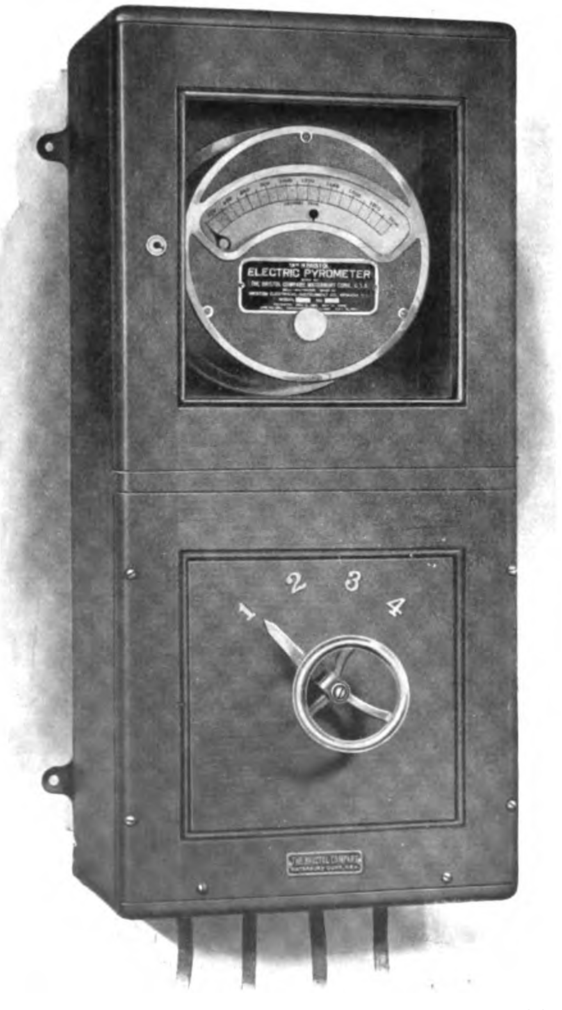

Fig. 11—Indicating instrument for electric pyrometer, with extra compartment containing rotary switch

Fig. 14—Ink type of recording pyrometer

tions may be made for 5 deg. each, making it possible to easily estimate to a fraction of these 5 deg. divisions.

Automatic Compensators

For many operations it is important that the temperatures be maintained very constant or that they be known very accurately, and it becomes necessary to take further precautions regarding the temperatures at the cold ends of the thermo-couples than shown above by the descriptions and illustrations of the extended couples. For such refined measurements, which are becoming more and more necessary, allowance must be made for changes of temperatures at the cold ends of the couple or means must be provided to maintain them at a constant temperature. A constant temperature at the cold ends is sometimes artificially produced by immersion in ice water or by having a waterjacket around the ends, through which water is made to flow. Except for laboratory and test purposes these artificial methods of taking care of the cold ends by maintaining them at constant temperature are as troublesome as they are expensive.

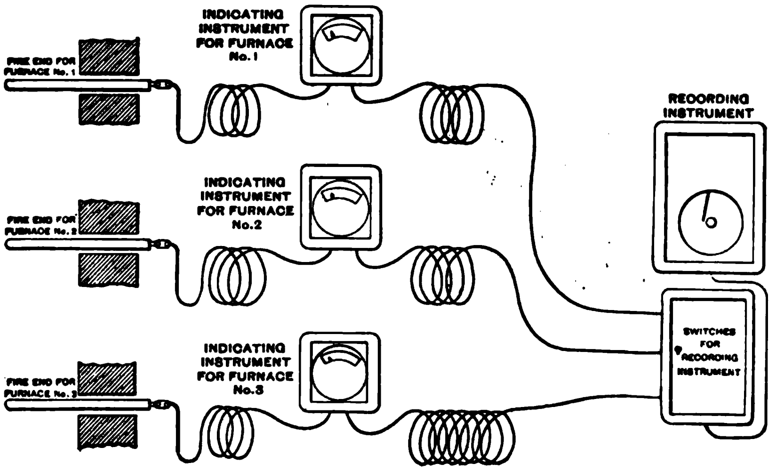

Fig. 12—Diagram of recording instrument in combination with three independent indicating instruments

In a low resistance thermo-electric system comparatively small changes in the actual resistance of the circuit, including the couple, leads and instrument, will produce sufficient effect to correct for the average changes at the cold ends of the thermocouple. A compensating device to automatically correct for changes of the temperatures at the cold end of a thermo-electric couple has been devised, which makes it possible to eliminate the need of any corrections for changes of temperature at the cold ends of the thermo-couples and to dispense with artificial means of maintaining the cold ends at constant temperatures.

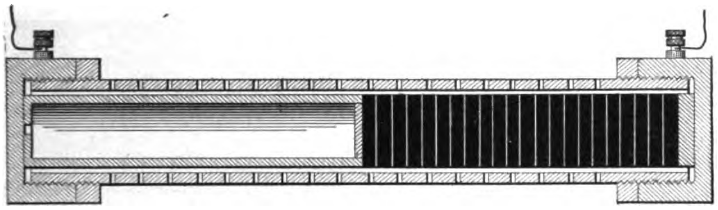

Fig. 16—Cross section of a new model of unbreakable compensator

An especially useful device, which is illustrated in Fig. 15, consists of a glass bulb with a short stem similar to an ordinary mercurial thermometer. Two platinum wires are fused into same near its tip. These are connected within the flattened bore by a loop of platinum wire, thus completing the circuit as indicated in the diagram. The size of the bulb, the cross-section of the bore, and the cross-section of the platinum wire are proportioned to suit the particular instrument and its range.

This compensator will perfectly compensate for any particular point on the scale for which it may be constructed, as for instance at the working point where it is desired that the temperature shall be absolutely independent of the changes in temperature at the cold ends of the thermo-couple when the compensator is connected in series at the cold end of couple. It is evident that if the temperature rises at the cold end of the couple the mercury rising in the stem will short-circuit a portion of the platinum loop, thus reducing the resistance of the entire circuit by the necessary amount, so that the diminished electromotive force of the thermo-electric couple, due to the rise of temperature at the cold end, will cause the same amount of current to flow through the instrument, and give the same reading, as if there had been no change of the temperature at the cold end of the couple.

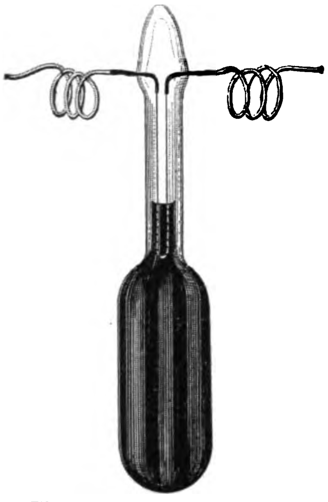

Fig. 15—Compensating device used in automatically correcting temperature changes

The compensator acts on the same principle but in a reverse manner when the temperature falls at the cold end, the resistance of the mercury being increased as the column of mercury falls. The increase of resistance in the circuit prevents an increase in the electromotive force of the couple due to the fall of the temperature at the cold end from increasing the current through the instrument, and, therefore, the reading remains unchanged. It will be seen that the same type of compensator may also be employed within the indicating instrument to compensate for changes of temperature at the instrument which would have a tendency to affect its reading.

The automatic compensator described above has been used quite extensively and successfully. In adapting these compensators for commercial service extra care has to be taken in their manipulation. Being made of glass they are fragile and when turned upside down, as sometimes occurs during transportation, the column of mercury is liable to separate in the stem.

To meet the demand for an automatic compensator which would overcome the difficulties mentioned, one has been devised which is illustrated in Fig. 16. The operation of this new model depends upon the differential expansion of a piece of metal and the tube encasing it. The tube is made of an insulating clay material, which has a very low coefficient of expansion. A tube

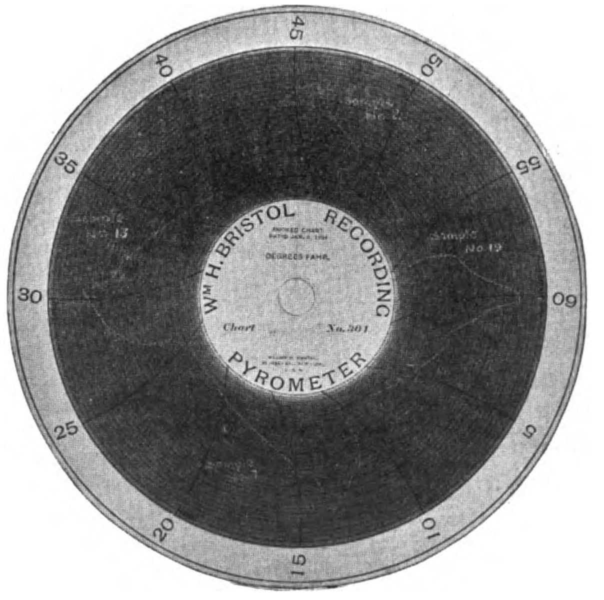

Fig. 13—Reproduction of a smoked-chart record made in determining absorption and recalescent points of metals

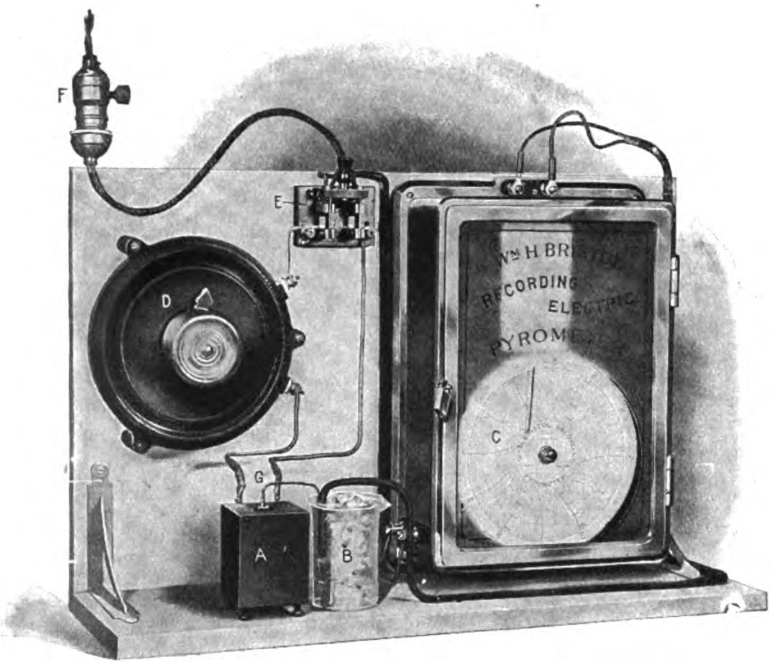

Fig. 17—Recording pyrometer, electric furnace, rheostat and connecting plug

of zinc is placed inside of the clay tube, which about half fills its length, the balance of the space being filled with discs of pure graphite. The ends of the tube are covered with metallic caps provided with screw threads and lock nuts. Electric connections are made to the caps at the ends of the tube, and the compensator is placed in series with the leads to the instrument close by the cold end of the thermo-electric couple. In Fig. 16 a cross-section of the compensator is shown, and if connected in series at the cold end of the couple its operation is as follows: When the temperature at the cold end rises the zinc tube expands more than the clay tube, and a pressure is brought to bear upon the graphite discs which reduces the resistance through the circuit from the cap at one end to that at the other where the connections are made. If the temperature at the cold end of the thermo-couple falls the zinc tube will contract, reducing the pressure and correspondingly increasing the resistance through the graphite discs.

By initially adjusting the resistance, by means of the screw caps and lock nuts, it is a simple matter to make the initial resistance such that if the temperature rises or lowers at the cold end of the thermo-couple the resistance of the compensator will be diminished or increased by the proper amount, so that the reading on the instrument will not be affected by the change of temperature at the cold end.

This compensator has not been tested out in practice, but as it will stand rough handling without any change in the resistance it is hoped that it will prove valuable in meeting the great demand for a practical automatic compensator for commercial use in connection with the thermo-electric couples.

In hardening, tempering and annealing, and other heat treatment of steels for the various parts of automobiles, since various grades of steels are used in these parts, it is an important matter to have pyrometers which can be depended upon to accurately indicate and record the temperatures during the processes and treatment of such steels.

It is a comparatively easy matter to injure steel by overheating, but by the proper use of an accurate pyrometer such mistakes are absolutely unnecessary.

As is well known, it is impossible to harden steel unless it is heated beyond the absorption point; therefore, one of the important applications of a pyrometer in this connection is to determine the absorption point. This can be done by using the apparatus shown in Fig. 17, consisting of a recording pyrometer, a small quartz-lined electric furnace, with a rheostat for regulating temperature and plug connection for attaching to lamp socket. *(To be continued)*

Digest

BRIEF RÉSUMÉ FROM 50 FOREIGN PAPERS: WORK OF A TESTING STATION—METHOD FOR REDUCING THE HEATING OF LUBRICANTS—DIFFERENCE BETWEEN TIRES—THE E. N. V. MOTOR—PHOTOGRAPHS OF EDDIES—BRAKING BY MOTOR—HINTS FOR EXPORT

Among the tests which have been demanded of the Section for Metals in the *Laboratoire d'Essais du Conservatoire des Arts et Métiers* (Testing Department of the National Conservatory of Arts and Trades), Prof. L. Guillet of this institution mentions the following in the report for 1909 just published: Mechanical and micrographic tests on a rail broken by the passage of a train, on tubes and sheets from boilers which had bursted, on chains and cables broken in service. A series of tests was made with lubricating oils and with various anti-friction metals to determine the coefficient of friction and the consumption of oil in terms of speeds and pressures. Micrography has been used right along, and has revealed particularly cases of *écrouissage* in metallic pieces only a short time in service (*écrouissage* is a deterioration of the fibre of metals, akin to fatigue but ascribed especially to the processes of cold drawing and rolling). Construction pieces and materials used in aviation, especially cables, shafts, propellers, cords and cloths, have occasioned more and more numerous tests. In the section for machines tests have been made of steam engines, internal combustion engines, gas producers, hydraulic machines, autmobiles, ventilators, etc., also tests of aerial propellers of various designs and of aviation motors. In the chemical section many of the examinations and reports have been supplementary to those in the mechanical sections, such as with reference to lubricants, rubber, fuels, metals and other construction materials. —*Le Génie Civil*, July 16.

For testing oils and bearing metals the Conservatory of Arts and Trades has two Martens machines which measure the coefficient of friction at pressures up to 100 kilos per square centimetre at speeds up to 6 meters per second, and up to a temperature of 80° C. In order to study oil heated up to 200° the laboratory makes use of a Kappf machine, consisting of a tub, or churn, in which a stem is turned by an electric motor, the stem being charged with variable weights and rotated at variable speeds. By means of the Martens machine it has been possible to show how an oil acts with regard to heating and consumption when the load and speed are varied. To this end the machine is operated at constant speed and pressure and the increase of temperature as well as the oil consumption are measured. This is repeated with the required changes of speed and pressure, one or both of these factors being kept constant throughout each test. One arrives by this method at a remarkable differentiation between oils and is able to establish the two characteristics which are of especial interest to the consumer. For the same oil it has been determined that: (1), at constant speed the coefficient of friction diminishes rapidly when the pressure increases, passes through a minimum and then rises at pressures varying generally from 60 to 80 kilos per square centimeter; (2), at constant pressure the coefficient of friction increases with the speed at low pressures, thereafter passes through a stage where it is reduced with the speed and finally increases with the speed at high pressures. The question is throughout of the friction coefficients at equal temperatures. At constant speed the time required for reaching a given temperature diminishes with the increasing pressure according to a law which appears complicated, but which the operators of the Conservatory expect to be able to formulate before long. "The Martens machine," says the report, "has permitted us to place in evidence by special tests a certain favorable influence on the friction obtained with an oil, which may be secured by introducing in this oil a somewhat volatile lubricating product which will vaporize slightly when the oil begins to get warm and by grace of the latent heat absorbed in vaporization will retard this heating of the oil. By this method it has been possible to lubricate with superheat oil, thick and viscous as a syrup, and which was injected in the machine by means of compressed air at a pressure of 8 kilos per square centimeter.

"The metals which are studied by the aid of this machine are formed as small bushings, and it is possible to determine on these bushings, besides the factors mentioned, also the amount of metal removed by friction. In this respect the metals vary considerably from each other. Some of them show a loss which is negligible, while others, especially the phosphor bronzes, lose too much of their substance by detrition, though their friction coefficient is low."—*La Technique Automobile et Aérienne.*

With reference to the wearing qualities of rubber tires P. Breuil states in the annual report of the Conservatory for Arts and Trades that the tests conducted at this institution show that some of the rubber mixtures used in tires wear ten times as long as others under the same operative conditions, so that there is plenty of room left for continued experimentation and testing, even though rubber may properly be classified as "an organic material which has strayed into mechanics."

A cursory description is offered of the E. N. V. motor, which shares with the *Gnôme* the preference of the most successful French aviators. The 8 cylinders form a right-angled V with four in each branch. The shaft has four crank pins disposed in pairs 180° apart, six ball bearings and a ball end-thrust bearing to receive the pull or thrust of the propeller. The cams are integral with the hollow camshaft which serves all eight cylinders, the admission and exhaust valves being placed side by side in individual valve chambers for each cylinder, these valve chambers extending L-wise and inward from the top of the V. The axes of the admission valves are inclined with relation to the axes of the cylinders, by which provision dead space is reduced. The crank pins and crankarms are bored to carry lubricant by force feed to all shaft and connection rod bearings, and from the pins the oil is sent through the hollow connecting rod to the hollow piston pin, and thence to the piston, but a special provision prevents exit of the oil to the bearing surface of the piston until the latter is at the end of the power stroke. (So says the description, but gives no details explaining how an emission of the oil at the end of the suction stroke is prevented. The provision carries into effect the old demand that the main oiling of the cylinder should take place at a definite point in the cycle of movements, so that the relation of the lubricant to the heat generation may be constant and subject to rational regulation. Possibly the cylinder lubrication is limited to the period at the end of the power stroke by synchronizing the strokes of the oil pump with the cycle of the motor).

The walls constituting the water jackets for each cylinder are formed of copper precipitated by electroplating process, and internal partitions are provided in the jackets to regulate and retard the cooling. The water circulation is forced by a small turbine wheel, and the radiator is placed underneath the crank-chamber in the direct current of air produced by the forward movement of the aeroplane. The ignition is by magneto and storage battery, each system having its own plugs. The distributor for the battery ignition is operated from the end of the camshaft.—*Le Génie Civil,* July 16.

Photographs of the eddies produced by an atmospheric propeller have been taken by novel means by A. Tanakadate. He sends a stream of hot air into the cold air and thereby produces certain variations in the refraction of the light and these become visible to the camera by a quick and strong flash-light. While the hot air has a movement of its own, determined by its variation in temperature from the rest of the air which is agitated by the screw propeller, this is negligible in comparison with the much more violent movements caused by the latter.—*Comptes Rendus de L'Académie des Sciences,* July 18.

For mountaineering by automobile it is recommended to arrange a special air intake on the induction tube between the carbureter and the cylinders, and to provide means for opening this intake when desired, so that the driver, when descending long inclines, may admit fresh air to the cylinders under full compression and get the brake effect thereof, rather than cutting off both gas and air, as is more commonly done. In the latter case a vacuum is produced above the piston, and lubricating oil in considerable quantity is forced past the piston rings into the combustion chamber, where it will foul the spark plugs.—*La Pratique Automobile,* July 25.

Hints for export, in some instances relating to construction, have been compiled by a German engineer from various reliable sources. None of the data are older than the end of 1908. They are, in abbreviated substance, as follows: Imports to Russia in 1908 amounted to 3.1 million rubles, of which sum 2.8 million was for trucks or touring cars with at least four seats, and only 0.3 million for runabouts. Most of the motor trucks and omnibuses came from Germany, and most of the pleasure cars from France. In Holland the best market has been for very light vehicles at 2,000 to 3,000 francs ($400 to $600). In Egypt the demand has so far been for closed carriages of small power. Larger automobiles have been bought somewhat extensively by the ministry of finance for use by the road and street departments and by the gendarmery. The imports to the Cape Colony have reached 60,000 pound sterling annually since duties were lowered in 1906. The cars must be high and stout for rough use over the veldt. They are indispensable for communication between the cities and the mining districts, and are used in preference to the railway for one hundred mile trips by engineers and inspectors. British India, in 1908, took automobiles to the value of 6,344,300 rupees, of which the shipping trade of England received 5,294,400; Belgium, 609,700. The market is now depressed by over-imports. American cars at 3,500 to 4,000 rupees have lost ground in Bombay, where the demand is mostly for large, expensive cars, up to $16,000 apiece, for the rich rajahs, merchants and government officials, who use them for lengthy trips to the inland. The gasoline and oil tanks must be large, spare parts amply provided, and there must be provisions for strapping considerable baggage to the vehicle. For city use, to take the business men from the remote residence sections to their offices, a consular report says that cars of 16 to 30 horsepower are preferred, and that the carriage work should be conspicuous in design and color to meet the native taste, red leather being much liked, and the vehicle should be low, easy of entrance and noiseless. Single-cylinder De Dion cars of up to 8 horsepower, and with four seats, phaeton style, are sold in considerable number at 4,500 rupees. The French firm, Chenard-Walcker, has sold many chassis to which are fitted Indian-made bodies constructed from woods suitable for the climate. In Siam the demand is mostly for small automobiles of 12 to 16 horsepower and with closed or semi-closed bodies. Argentina has few roads. American high-wheelers from Chicago have been sold there to some extent. In the cities nearly all cars are French or Italian. The market in Brazil is limited to the city of Rio Janeiro, where 350 automobiles are in use, many of them bought in Paris by their owners on the occasion of European trips, and in the central State of Sao Paulo, where the country is flat and rich. The Australian yearly import trade in automobiles is represented, according to recent reports, in the sum of 262,000 pound sterling, of which the United States received 14,300 and England nominally 166,000.—*Zeitschrift des Mitteleuropaeischen Motorwagen Vereins, medio* July.

Don't

ANOTHER INSTALLMENT OF SHORT-METER ADVICE TO THE TYRO—AND THE EXPERT—THE FOLLOWING OF WHICH MAY SAVE THE MOTORIST HEAPS OF TROUBLE, PERHAPS SOME MONEY, AND PROBABLY A LAWSUIT OR TWO

Don't run the motor on a retarded spark; it is damaging to the motor; excess heat is the first manifestation; leaky valves follow; weak performance is the further expectation.

Don't let calcium carbide ash remain in the generator after it has rendered a good night's service; the residuum (ash) is a biting mass that will ruin the generator and compel the purchase of a new one; it takes but a moment to clean out the generator.

Don't expect a raw patch to stay on a tube; it is like a scab; it will fester and peel off.

Don't think that it is an extravagance to purchase a vulcanizer.

Don't have a vulcanizer and not use it; tire-life depends upon care; the latter without a vulcanizer is impossible.

Don't have lubricating oil in such quantity that you can afford to let it drip on the garage floor; it ruins tires. If, through some inadvertence, oil gets on the floor, clean it up before the car is rolled in; one daub of lubricating oil on a tire and it will depreciate perhaps 50 per cent.

Don't fail to place an adequate supply of lubricant in the case with the inner tube in putting a tire on. What is lubricant for tubes? Talcum!

Don't be careless when putting tires on; the inner tube should be carefully inserted; laps are sure to do damage; just take the extra moment to examine the inner tube and see if it is properly in place.

Don't stand in your own light; cheap lubricating oil is the most efficacious means for a high cost of maintenance.

Don't labor under the impression that quantity will suffice for quality when it comes to lubricating oil; make it quality first, last, and all the time.

Don't get the impression that a gallon of good lubricating oil in the "sump" in the lower half of the crankcase will be of any value in keeping a main bearing from freezing; better results will come from a drop of oil on the bearing surface—look after the circulation.

Don't be fooled by the chauffeur who keeps the brass work polished; you can get that work done for a nickel by a bootblack; see that the "man" cleans out the gearcase, crankcase, and other lodging houses for stale lubricant.

Don't handle a squirt-can as if you are trying to put out a fire; clean out the oil-hole and then properly insert the spout of the can in place and make sure that a few drops of the lubricant will reach the surfaces to be lubricated.

Don't forget that lubricating oil wears out just as shoes and other things depreciate in service. Clean out the old oil before putting in new—what's the use of spoiling the new supply and defeating the aim.

Don't forget to take the jack along.

Don't high-gear it to a mud hole in the road; you cannot be sure of the depth of the hole; go slow; use the low gear; that is what it is for.

Don't race down every hill you come to just to get up the impetus necessary to make the facing grade on high gear; what is the matter with using a lower gear on the hill?

Don't forget that trouble hates a systematic man.

Don't persuade a lazy chauffeur to use the seat in your car as a bed to sleep in.

Don't expect to procure all the Cardinal Virtues for $15 per week; a good chauffeur is worth a price.

Don't forget, it is not what a man knows, but what he does, that is worth money. Get a chauffeur that knows less if necessary.

Don't fail to strap the top down to prevent breaking the bows.

Don't lose hub-caps off a wheel and then run the car for a thousand miles without them; caps are placed to keep dust out of the bearings.

Don't ignore a squeaking sound for a moment; it means that some bearing is crying for lubricating oil; it knows what it wants; be accommodating.

Don't let your "profound" knowledge interfere with your success; an absent-minded moment may cost you a crankshaft; there is danger in racing the motor.

Don't run your car week after week without cleaning out the gasoline tank and piping, even down to the carbureter; water accumulates and leads to trouble on the road.

Don't allow yourself to be persuaded that a screen or a chamois skin will abort water trouble; they may be the cause of it.

Don't imagine that the carburetion is perfect just because there is no frost on the intake manifold; poor gasoline may be in use. If so, it will not evaporate until it contacts with the heated cylinder walls, and in this fact may lie the reason for the absence of frost on the surfaces of the intake manifold, and carbon trouble with the motor.

Don't understand that it is desirable to have a frost accumulation on the surface of the intake manifold; far from it, but heat must be supplied to the liquid gasoline in order to vaporize it; this heat should be supplied to the same before it enters the cylinders.

Don't jump to the conclusion that the chauffeur is incompetent just because you have indigestion—his stomach may be in good working order.

Don't be a road hog; you are only one in 90,000,000. If you want a whole road for yourself, build one in your own back yard.

Don't give the repairman *carte blanche* if you only want him to generate a $10 repair bill.

Don't assume too much; the repairman is working for number one; to him, you are number two.

Don't go to a repair shop without having a schedule made of the work to be done; make it clear that you know what you want; stick to the schedule; insist upon getting what you pay for and pay for what you get.

Don't let the repair man mumble the price; there may be a lurking difference; have it put down in black and white.

Don't think that all repair men are robbers; some of them are so honest that they scarcely make both ends meet; it is too bad to have a good repair man go out of business because he does not know how to charge; if you are in the sugar business and sell 15 ounces to the pound, you can afford to treat him liberally, but if you give full measure you will understand his motive.

Don't be surprised if the spare tire that you left exposed to sun and weather for six months proves to be short-lived; tires depreciate when exposed to light as well as to weather; why not purchase a cover and use it?

Don't think that a 25-cent pump will do good work; a large tire pump is a paying investment.

Don't come off the road with your car all splashed up with mud and let it remain on until it forms a dry crust. It will come off, of course, but the varnish will adhere to the mud instead of the car.

Don't start rubbing down the varnished surfaces of the car before the sand is all removed; grindstones are made of sand; you might just as well use a grindstone.

Touching Up and Varnishing

DIRECTIONS FOR THIS WORK BY M. C. HILLICK. SKILLED HANDLING AND PROPER EQUIPMENT ARE REQUIRED

THE car that comes to the paint shop in a slightly soiled and worn condition to be simply touched up and varnished, or to be lightly painted and varnished, as the condition of the surface, upon examination, may suggest, invites careful handling and the best sort of skill to put it in proper shape again at minimum cost.

The first requirement to handle the automobile work economically is a good, light, well-ventilated working space equipped with either a floor pit over which to locate the car, or a couple of strong wooden horses securely bolted to the floor and reached by an inclined runway up which the car can easily be pushed or pulled.

At this elevation anyone can work under the car without much inconvenience. Having located the car so that the parts may be cleaned handily take narrow strips of burlap, say 3 inches, and saturating a small bunch of waste with turpentine proceed to wet up the old crusty accumulations, after which rub smartly with the strips of burlap. Some parts naturally will need, and in fact, must have, more or less scraping with either the putty knife or steel hook scraper in order to start loose and clean off the unusually hard, crusty substances. After the mechanism has been scraped and rubbed clean of the grease and dirt, wash the parts off, as a final cleaning process, with turpentine, and dry off, after a few minutes, with clean strips of burlap. In case a car is received with the parts so unusually crusted over with grease that it cannot be moved with the ordinary medium, start the accumulations with the scraper, and then apply soft soap carrying a small quantity of sal-soda, and use a handful of coarse hair to scour the surface with. The main thing is to get the surface clean before going forward with other operations.

Rub the body surface with pumice stone flour to eliminate dirt specks in the former coats of varnish; also, to flatten out and make the old surface of varnish fit to receive the new supply of paint and varnish.

If the surface discloses a condition which a single coat of varnish will amply renew, and furnish a body of sufficient brilliancy, proceed at once to match some color to the old color, to accomplish which use enough rubbing varnish in the match color to cause it, when applied to the surface, to dry with enough gloss to counteract the natural light-absorbing properties of the new color.

Where the color dries "dead," or without gloss, it invariably absorbs more light than it reflects, with the result that the match is almost certain to be of a different shade—possibly several shades—from the old color. With enough varnish in the match color it undergoes practically no change in drying out, and if mixed to match precisely, or nearly so, the old color, it stays so throughout the drying process. However, at best it is almost next to the impossible to make all colors match up exactly, and the necessity, therefore, of touching as few places as possible, and those places made of a size just sufficient to cover the surface defect, is at once apparent. Assign this work to one of the most skilled as well as one of the most painstaking painters. Moreover, touch only the actual defects. This applies to all parts of the car, body and chassis. In touching up use a small pencil brush, preferably. Give the match color plenty of time in which to dry before varnishing, otherwise not a few colors will be found to show anywhere from two to four, or more, different shades of the same color. Having deftly touched the parts requiring such work, and the touch up spots having dried thoroughly, wash the surface throughout very carefully using a water tool or brush to work about all moldings and carvings, etc., thus removing pulverized pumice stone accumulations, and any other adhesive particles, in fact. With special dusters, dust off all the surface perfectly, after which flow the surface—the body surface first—with a rich, full coat of some wholly trustworthy elastic finishing varnish. Handle the chassis similarly, coating up with all the varnish the surface will safely take care of.

The automobile that shows the surface bitten with minute missiles, with worn patches, and possibly some parts faded and perished quite beyond touching up properly, but which the owner is anxious to have put into presentable appearance at a minimum cost, may be treated about this way: Wash and clean up body and chassis as described in the preceding case. Detach as many of the parts as may be necessary to facilitate operations.

Then with pulverized pumice stone, flour and water rub the surface of the car down uniformly throughout body and chassis, washing thoroughly. Then make choice of some good, opaque, one-coat color, approximating the old color sufficiently to render such color a fit supporting ground for the new, and mixing it with raw linseed oil and turpentine in the proportion of one part oil to eight parts turpentine, apply to the surface using a camel's hair brush for the work.

However, should the surface be fractured and chopped up some with nicks and gouges, before applying the coat of color it should be touched over such surface defects with a bit of lead and color, or with color alone, either pigment containing a dash of raw linseed oil as a binder. The following day putty the cavities and fractures with a hard drying lead putty, made, say, of three parts dry white lead and one part potted whiting worked to the proper consistency in equal parts of brown coach japan and quick drying rubbing varnish. Let this putty stand 24 hours and then level down to the main surface with a block of rubbing brick or stone and water. This brings the surface to a level and uniformly intact condition throughout, and after twelve hours for drying out the color, as already detailed, may be laid on.

On this flat color apply whatever lines of striping the car owner may choose, or delegate you to choose, after which, as quickly as the lines are safely dry, flow on a full, generous coat of heavy body finishing varnish. Brighten up the polished fixtures, renovate the top, if any, and report the job finished.

Should the surface be parched and poverty stricken in the body of varnish, and lacking in capacity to hold out with adequate brilliancy the proposed new coat, it may be necessary to apply a coat of rubbing varnish directly upon the new coat of color, in which case the rubbing varnish should carry a stain of the new color in order to counteract the discoloring property of the varnish.

In due time—this time, of course, depending materially upon the drying conditions of the shop—rub down nicely with pumice stone flour and water, wash perfectly, and finish with the varnish recommended for the one coat varnish method. When the rubbing coat of varnish is used with color in the varnish, apply the striping on the rubbing coat after it has been surfaced with water and pumice stone. If the rubbing varnish is used clear, stripe upon the flat color, thus giving the lines the protection of an extra coat of varnish.

Should any material be applied to the automobile top use it sparingly—the least used, in fact, the better.

Contests on Highways

LEGALITY OF PRE-EMPTING THE HIGHWAY FOR CONTESTS.
BY XENOPHON P. HUDDY, LL.B. INCLUDING A DISCUSSION
OF OTHER PHASES OF THE MATTER

FOR a number of years automobile speed contests have been held on public highways and also on private courses. Experience has taught that there exists more or less danger connected with automobile racing. It is fitting to inquire if these races are legal. Automobile races tend to show the qualities of the cars participating. These speed contests also afford means of advertising good cars. They constitute what mignt perhaps be termed an excellent sporting event. They also bring business to the community and to the railroads. In considering the advisability of continuing racing of this character the fact that the contestants may be gambled over is not a good argument for abolishing them, since it is possible to gamble concerning anything.

The most serious element entering into automobile racing consists of the danger to life. Are the advantages derived from automobile speed contests on public and private ways greater than the disadvantages? We must concede that in almost every line of human activity and progress the sacrifice of life is inevitable. Our railroads could not be operated without at least a certain number of persons being injured or killed each year. The fact that persons may be injured or killed is no legitimate argument to be advanced for the purpose of discontinuing any particular line of necessary commercial or other activity of great benefit to the public, but in automobile racing are there not features which present very serious consideration in determining whether it should be allowed to exist?

What may the government if it wishes do about automobile racing? The State does not possess authority to prohibit anything it pleases. There exists, especially in the United States, a guarantee of individual freedom and liberty which permits a person to do about as he pleases, if he does not injure either the person or property of another, and if he does not commit any wrong against the public. Prohibitory legislation without reason is illegal, therefore the government cannot arbitrarily command that a particular act must not be done.

The vital legal question concerned in holding automobile speed contests on the public ways consists of two propositions: first, whether a public way can be closed for any length of time for the purpose of holding a speed contest on it and, second, whether such a speed contest does not constitute a public nuisance even though the authorities close the highway under color of authority. We will consider racing on private ways later.

The public avenues of travel were established for certain uses. These uses cover the passing of vehicles, animals, and pedestrians, also they consist of affording a thoroughfare for the placing of telephone and telegraph poles and wires. All these constitute legitimate uses of the public highways, since they are all connected with or in aid of travel, intercourse and communication.

Now, what legal grounds exist for closing the public highways? Manifestly necessary and proper improvements may close a road or street, such as excavations, laying of sewer or water pipes and railroad tracks. So too, a house may be moved through a street and the thoroughfare temporarily may be closed for that purpose, but no longer time than is absolutely necessary to move the house can be taken. The nearest thing which approaches an automobile race, perhaps, is that of a parade, but because parades are educational and inspire patriotism they have been held to be legitimate causes for temporarily closing public avenues of travel.

An automobile speed contest held on the public highways stands in a different position from any of the foregoing. It is not a public necessity, nor is it a public utility. The fundamental theory that a public way may be closed for a public purpose using the same reason that private property may be taken for a public purpose does not apply to automobile racing. An automobile race is not held for a public purpose. It may be said that automobile racing has a tendency to develop and perfect the automobile. If this were the only result such speed contests would be legitimate. The danger, however, which is connected with holding these races, and the closing of the public highways, are sufficient to stamp them as illegal it may be argued. Suppose that one desired to hold a funeral, or suppose a house caught on fire, could the funeral or fire engines be stopped because an automobile race was being held?

The common law on the subject is as follows:

"To operate a vehicle along a public road or street, greatly to the danger and inconvenience of all persons traveling along said highway, is such a wrong as injuriously affects the rights of the public, who are entitled to travel along such public thoroughfare, laid out and kept up by the public for their convenience and accommodation, without exposure to such danger and inconvenience. While any person may drive his vehicle at such speed as he may please, yet, in enjoying the privilege of free use of his property, he has no right to expose others to injury or to infringe upon the rights of the general public. Running and racing a vehicle along a public road, no necessity being shown for such speed, is not the ordinary and proper mode in which such roads are used by prudent men. They were not intended, by the very purpose for which they are opened and kept up, for any such use, but for the ordinary and usual travel of the public.

"To run a race on a public highway or to excessively speed a vehicle, to the danger and inconvenience of people, is a common law misdemeanor. It is to add, that there may be necessity for riding at high speed along even the public road, as in cases of sickness, or to give a neighbor notice of great personal danger to his property. Such necessity is a matter of defense."

Considering the holding of automobile races on private tracks there are difficulties standing in the way of controlling these races by legislation.

Prize-fighting is conducted on private property, but the government has the power to legislate against it, or to control it to a considerable extent. Duelling also which may take place on private property can be prohibited and is prohibited throughout the civilized world excepting one or two places. In fact, any conduct, whether it takes place on private or public property, may be regulated or prohibited if it has a tendency to destroy human life, because it is considered that dangerous acts constitute a wrong against the community and that the people are sufficiently interested in dangerous conduct to prohibit it. It might be argued, what business is it for the people or the government to prohibit a chauffeur from driving a high-powered machine in a speed contest on private property. May I not do as I please with my life and limb? The answer to this question is, no. Self-inflicted injury is illegal. Suicide has always been considered a felony. An attempt to commit suicide is punishable. Of course, for one to knowingly and intentionally engage in a highly dangerous act cannot be placed in the same category as suicide, but where the act has no direct public benefit it can be controlled more or less by legislative action.

In some of the States automobile laws prohibit the holding of speed contests on public highways. No statute has as yet made an attempt to declare it unlawful to race on private ways.

Motor Valves

ABSTRACTS FROM THE THIRD INSTALLMENT OF PAPER BY EUGENE P. BATZELL READ AT SUMMER MEETING OF SOCIETY OF AUTOMOBILE ENGINEERS DEALING WITH SLIDE, ROTARY AND PISTON VS. POPPET VALVES

STILL another type of valve is shown in Fig. 12, designated by the author as a "simple barrel type of rotary valve." In relation to barrel types of rotary valves the author goes on to say: "Cylinder or barrel types of rotary valves also give triangular opening diagrams. The simplest of these is represented in Fig. 12. Here a valve *a* is formed with a straight central passage *b* through which the inlet and exhaust passages communicate with the interior of the cylinder at the proper moment. This valve rotates at 1-4 crankshaft speed. With an inlet of 210 duration the valve channel can occupy at each end an arc of 26 1-4 degrees, if the greatest possible inlet opening is desired. In such a case the inlet port of the cylinder head will also extend over 26 1-4 degrees, and the exhaust port for 225 degrees duration over 30 degrees. For a cylinder of 5-inch bore, the valve could be made about 3 inches in diameter with a channel 4 inches long." The author gives the maximum inlet area as equal to that of the channel passage, or 2.75 square inches. He estimates that this opening will be 25 per cent. larger than that with poppet valves.

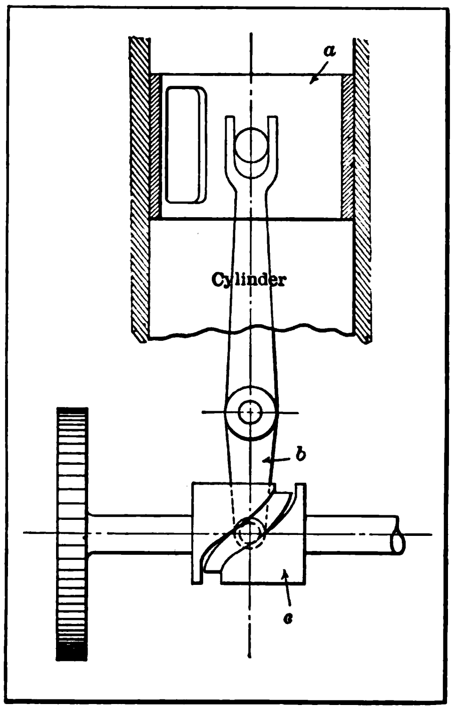

Fig. 13—Cam-operated oscillating valve

Besides a variety of other phases of the valve problem, the author touched upon the question of reversing and throttling motors by means of valves, which represents a phase of the motor building situation that is at present quite foreign to automobile practice. It is nevertheless an interesting angle, and nearly every autoist, at some time or other, has compared the automobile type of internal-combustion motor with steam engines, and regretted that the automobile motor seemed to fall short of the facility offered by steam engines from this point of view. The one redeeming feature lies in the fact that automobile motors do not have to be reversed. The sliding gear transmission system permits of reversing the direction of travel of the car without reversing the motor. In relation to reversing and throttling motors, the author goes on to say: "The motor of a rotary valve system generally can easily be made reversible by reversing the direction of valve rotation, or by changing the moment of the inlet relative to the exhaust, which can be accomplished by an auxiliary valve. An auxiliary valve can be used conveniently also for a throttling means for the motor. Such a valve can be placed between the inlet valve and the cylinder port, so as to alter the size of the opening, or simultanously its size and duration. The inside member of the inlet valve in Fig. 12A serves the last purpose; it does not rotate but can be turned more or less, whereby its channel changes the direction, altering the inlet, timing and opening. However, neither reversibility nor throttling by the valves is to be considered as a feature of rotary-valve systems exclusively. With poppet and other valve systems, these objects can be obtained with as little complication, though in different ways.

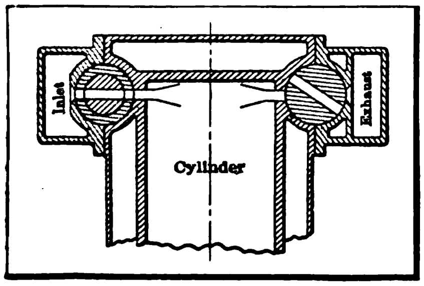

Fig. 12A—Double inlet valve

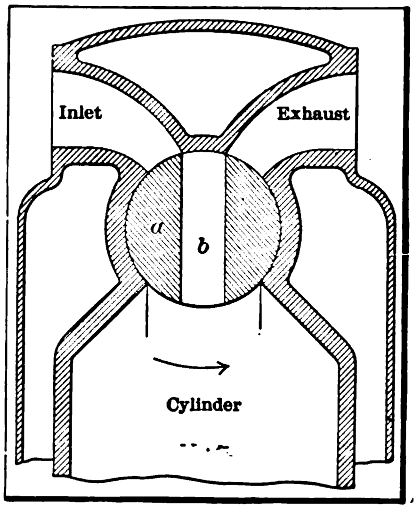

Fig. 12—Simple barrel type of rotary valve

"Referring to oscillating valves, similar to those just described as rotary systems, they can also be made with an oscillating motion. With the single valve of this type, proper engine timing will be obtainable only if the valve has an irregular motion, for instance, produced from a cam, etc. This is necessary because the time from the inlet closing to the exhaust opening is much longer than the time from the exhaust closing to the inlet opening. Double oscillating valves registering with each other similar to double sliding valve systems can have a continuous movement from eccentrics, or otherwise. In Fig. 13 a scheme is given of a cam operated oscillating valve. The groove cam *c* transfers motion to the valve *a* through a lever *b*. The valve can have a greater or smaller swing according to the cam size, the leverage, and other things. If it is assumed that the dimensions are such that a 3-4-inch maximum inlet opening is obtained, the diagram of the opening elapsing will depend upon the cam shape. If it is the choice to make the cam so that its developed surface is like the one presented in Fig. 14, the inlet and exhaust periods will be in their proper relation. It will be seen that the valve openings change in size in proportion to the revolving of the cam, but their maximum port openings remain unchanged for a certain period of time. If the valve opening increases and decreases at the same rate, its diagram will be a symmetrical trapezoid as given by curve v_4 in Fig. 4. The maximum port area remains constant for a period of 50 degrees crank motion. The respective theoretical intake gas velocity is

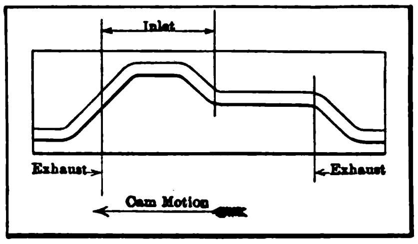

Fig. 14—Diagram of cam for actuating oscillating valves

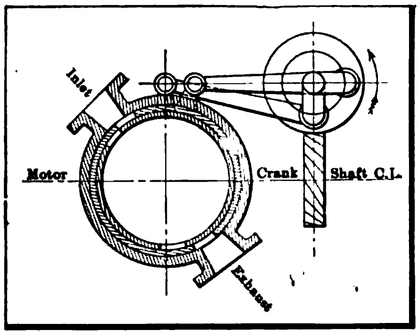

Fig. 15—Horizontal section through motor cylinder, showing oscillating double-valve system

represented in Fig. 4 in curve w_4. This system can be looked upon as being very favorable for motor power, but it still remains to be seen how it can be developed to become of practical value. The comparatively small movement of the valve should also give it some advantages, but, on the other hand, it would probably be difficult to preserve this mechanism from showing backlash, owing to wear in the cam and the pivot. In Fig. 15, which is a horizontal section through the motor cylinder, is shown an oscillating double-valve system with sleeve valves operated by rods from cranks, moving in the horizontal plane. These cranks are rotated from the motor crankshaft by means of a pair of spiral gears. The valve port diagram is obtained in the easiest way graphically. In laying out it is assumed that the radius of the valve crank will be 1 1-2 inches, and that the outer sleeve valve will be actuated from the crank, which revolves 75 degrees ahead of the other one operating the inner sleeve. The maximum inlet port size, counting on the circumference of the inner sleeve, will be found to be 15-16 inch, which gives a total area of 2.625 square inches with a port 2 inches high. The curve resulting from the performance of a motor such as this appears to be practically an equilateral triangle, and as such will result in a theoretical intake gas velocity curve of a shape similar to w_2 in Fig. 4, but of a slightly different scale. The curve v_5 starts and ends more lingeringly than curve v_2 and proves that the generally claimed quick opening of ports by means of a double-valve mechanism operated through eccentrics occurs less quickly than with regularly moving rotary valves. The double oscillating valves of the size assumed here are not noticeably different from the poppet valves in the area enclosed by their diagram curve. The curve v_6 gives a trifle quicker opening start than is obtained with Nos. 1 and 2 (Fig. 1), of the roller cam follower. On the other hand it is less quick than the curve of follower No. 3 (Fig. 1), and besides it is enclosed by all three cam-follower curves during a considerable part of the following crank movement; but it can be concluded that the system after Fig. 15 is more favorable for efficient inlet gas flow than poppet valves having a good shape of inlet port.

"Some other arrangements of oscillating valves are possible besides the one just referred to, for instance, double spherical cap valves are made to fit inside or outside the spherical combustion chamber, the motion for the valves being given through a pair of eccentrics. This system shows the same valve diagram as Fig. 15 and from a theoretical standpoint it is equal.

"Regarding the construction of the valve operating mechanism, hardly any simplification will be noticed in oscillating valves comparatively with poppet valves; gears, shafts with cranks, or eccentrics, rods, bearings, etc., are as well required there. The care required to keep the motor in good shape of course increases with the mechanical complication. If poppet valves are liable to get out of order, the oscillating valves also have peculiarities of construction which will render their correct functions only temporary, nothing being gained in this respect. For instance, places liable to cause trouble in oscillating valves are the cams, the bearings, different joints and pivots, the valve ports themselves, which can burn out, etc. Wear occurring here might result in considerable play of parts, and their correct motion in relation to each other will become changed. In this respect rotary valve systems are different. Their drive through gears and shafts is of a nature where wear is not followed by play or backlash.

(*To be continued.*)

Industrial Aeroplanes

BY MARIUS C. KRARUP. DESIGNS OF AEROPLANES ARE SHOWN EMBODYING IMPROVED MEANS FOR SECURING EQUILIBRIUM AND SEVERAL NEW DETAILS OF CONSTRUCTION

CARPENTRY and dry goods are elements in aeroplanes which fail to inspire full confidence. The woodwork and the textiles absorb moisture from the atmosphere, expand and contract unexpectedly and, in conjunction with guy wires which refuse to stretch, shift strains from here to there without notice or outward indication. The tangled debris which submits itself to inspection afterwards is eloquently silent. The cause may have been a weakened part, the aviator's blunder or the inherent unreliability of woodwork joints.

Though textiles will probably remain indispensable for a long time yet, the mechanical mind looks forward to an aeroplane machine which shall be a reliable product of the machine shop in all its large responsible features—an industrial aeroplane which may be produced in large number and all alike by industrial methods. So far, constructions conceived under some influence from this idea have been frustrated by the weight limit; they were unable to leave the ground, and in this fatal failure their other merits or defects escaped discussion. It was too much to expect that a design which had been evolved experimentally with woodwork as a basis and piano wires as a source of salvation could be transferred bodily to an imitation wrought in tubing and brazed metallic joints.

The transition to the industrial aeroplane which nevertheless is foreordained, unless the most modern transportation machine shall remain an anomaly in the age which created it, must evidently be accompanied with the changes in design which the changes in material involve. If these changes include an increase in weight per square foot of sustaining areas, as they are likely to do at first, the sustaining capacity of the areas per square foot must somehow be raised. If they include an increase in cost of production, it is reasonable that great care should be employed to develop those possibilities for a ready and instinctive preservation of equilibrium which are known to exist, since they are developed in Nature's fliers, and which constitute the only safeguard against having a considerable value destroyed by a trifling accident.

Even from a purely economical viewpoint, improved means for securing equilibrium must be a prominent feature of the aeroplane which shall be more than a dangerous and fascinating toy. And the sportsman who insists that the dangers of the sport should be reducible in proportion to the skill he employs, can readily concur in this view.

An aeroplane which offers opportunities for an industrial development, one which places the preservation of equilibrium in the hands of the aviator even in severe weather and without too exacting demands for special skill and one whose leading features may be tried out without too sudden or too radical departures from existing design and materials, seems to be one of the necessities of the moment. With these leading and other more or less subordinate considerations in mind, the writer has

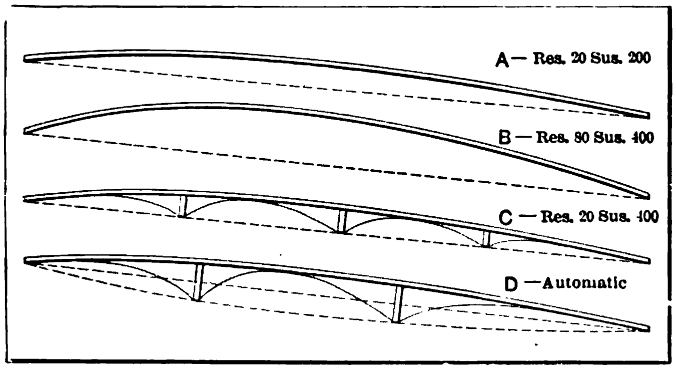

Fig. 1—Diagrammatic sections of aeroplanes illustrating the principle of placing curvature "in series"

developed a design for aeroplanes which, if it does not afford a starting point for a fresh development, should at least suggest some of the possibilities which must be materialized sooner or later. The accompanying drawings show an outline of the main features, and more detailed illustrations of the elements will be shown subsequently.

Certain peculiarities of the planes which may not easily be shown in drawings on a small scale are indicated diagrammatically in Fig. 1. It is known that a plane shaped in section somewhat as Fig. 1A meets with a resistance against propulsion which, at a given tilt and speed, may be denoted by the numerical value of 20, when the value of the sustentation which it affords at the same tilt and speed is denoted by 200. Another plane shaped, in section, somewhat as Fig. 1B meets, at the same tilt and otherwise similar circumstances, with resistance 80 and affords a sustentation of 400. The dimensions of the planes do not influence these relations much, excepting that the fore-and-aft extension should not be much more than one-fifth of the length of the front edge under penalty of excessive irregularity in the pressures created. The relations are in the main decided by the degree of the curvature. Such is, with only the inaccuracy of an extreme brevity, the upshot of the experimental research which has been carried on at various aerodynamic testing stations. The most desirable relation to establish in an aeroplane would of course be the combination of the resistance of A with the sustentation of B, provided the resistance of A is the minimum obtainable and the sustentation of B is the maximum obtainable. This combination may, in accordance with the established data, be effected in a considerable measure by placing the curvature of B "in series" under the general contours of A, as in Fig. 1C. Each of the subdivisions of plane C is thereby made to afford sustentation at the rate of 400, while the resistance, which depends very largely upon the shape of the top surface of the plane, remains essentially at the figure of 20. An uncertain element creeps in, because the air, in passing from under the foremost curvature in the series to the next one and from the second one to the third, is not in the same condition as the air of the atmosphere meeting a single hollow plane of larger fore-and-aft dimensions, and some experimenting is therefore necessary in order to determine what particular succession of curvatures in the series produces the best results. On the other hand, the pressures under, and over, a large plane of single curvature shift, with changes of tilt or wind, from the middle of the plane to an axis of pressures much nearer the front edge, and at very small tilts, below 5 degrees, as well as at tilts exceeding twenty degrees the shifting is sometimes rather violent and unaccountable. By placing the curvature in series the shifting of pressures should be distributed under the sub-curvatures and should be reduced in linear extension in proportion to the number of elements in the series. The arrangement indicated in Fig. 1C should therefore serve to increase the fore-and-aft stability as well as the sustentation for a given propulsive thrust. Finally, the formation indicated in Fig. 1D, in which the chords of the arcs of curvature themselves form a convex pressure surface for the plane in its entirety, should have distinctly self-righting qualities, since any tendency to tip forward or backward will be immediately antagonized by stronger or weaker action of the rear portions of the plane.

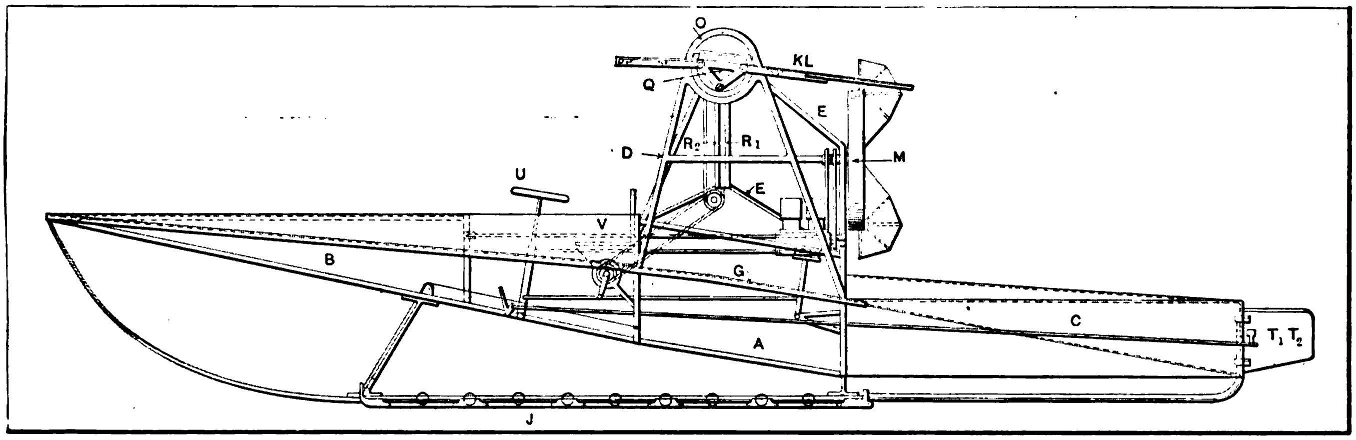

Fig. 2—Side view of machine with large upper adjustable wings and smaller fixed lower wings. A, body; B, prow; C, tail; D, left wing support; E, central control base; F, right wing support; GH, lower wings; J, skid; KL, upper wings; M, propeller; N_1 N_2, control levers; O_1 O_2, guard over trunnioned bearing ring; P_1 P_2, stays; Q, triangulated axis of wings; R_1 R_2, central slides; S_1 S_2, motors; T_1 T_2, oblique rudders; U, steering post; V, seat

In applying the design of Fig. 1C to practice it is found expedient to use the two upper spars in the triangulated axis, Q, of the wings KL, Fig. 2, as means for dividing the surface under the wings into curved sections or shallow air pockets.

In the aeroplanes outlined in the drawings, Figs. 2 to 5, the main upper wings *K* and *L* are designed on the plan of Fig. 1C with flexible and highly resilient sectional rear extensions intended to act as the springs on an automobile in permitting the structure to ride over humps in the road, *alias* sudden gusts, without deflection from its course, the flexible extensions allowing the gusts to pass while their resiliency determines the value of the extensions for sustentation in normal flight. The lower wings *G* and *H* are also designed on this plan but may approach the plan of Fig. 1D and may be without flexible extensions.

In accordance with the conditions for ability to preserve equilibrium, whether the machine is speeding along or the motor is stalled and gravitation is the only force available for propulsion, as these conditions have been analyzed in previous articles, the control is secured through the mobility of the main planes *K* and *L*, and the small oblique rudders T_1 and T_2 at the rear end of the tail surfaces are intended only as a handy means for control in fair weather and an auxiliary for difficult steering and alighting. In order to secure mobility of the planes without an impracticable employment of power, these have been suspended near their middles, where they are mounted in a trunnioned bearing ring admitting of their rotation around their rigid axes

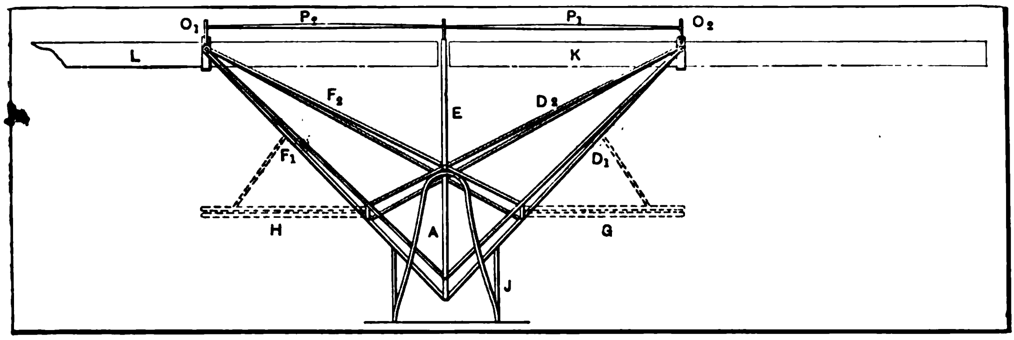

Fig. 4—Diagrammatic front view of construction applied to a monoplane or intermediate type

(formed of three trussed spars, shown as tubes) and also of raising their outer ends while lowering the inner ends, at which the control elements operate. One wing may be turned to a higher tilt while the other is at the same time and by the same control movement turned to a correspondingly lower tilt, or both wings may be tilted higher or lower in one movement. These movements may be accomplished whether the outer ends of one or both of the wings is raised or not.

The control devices serving these purposes consist briefly in two central slides R_1 R_2 in which the inner ends of the wings may slide up and down by means of sliding blocks and universal joints, the blocks being actuated through sprocket chains or equivalent means reaching lock-handles at the right and left sides of the aviator's seat. Two levers N_1 N_2 secured to the universal joints control the tilt of the planes. Their lower ends are held or moved forward or backward between rollers in a cable, one end of which winds on when the other winds off the steering post U, and, when the steering post is tipped forward or backward, both levers are turned correspondingly, thereby turning the planes. The two rear rudders T_1 T_2 placed at a V are actuated through pedals, and their action is accentuated by their position in continuation of the sharp rear edges of the covered tail portion of the structure, where the air displaced by the machine conflues.

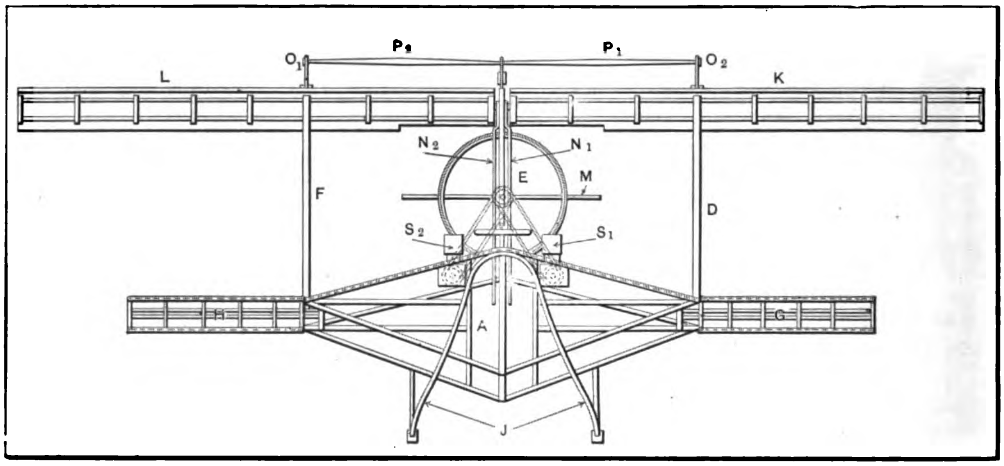

Fig. 3—Front view; reference letters denote the same parts as in Fig. 2

In order to support the planes under their middles, as well as their inner ends, it is necessary to have a rigid central body *A* and the uprights or standards *D*, *E* and *F*, and in order to reduce air resistance against this body, while also utilizing the resistance for sustentation and, withal, having this lower portion of the machine so shaped as to assist in securing a considerable measure of automatic stability, it is necessary to have a prow *B* and a tail *C*. Both prow and tail are covered, and the prow is formed of converging spars of which the upper one is normally horizontal, while the lower ones form supporting triangles with a forward tilt of about fifteen degrees and lateral tilts of about twenty to thirty degrees. The air waves created by the forward movement of the prow are caught under the fixed lower wings *G* and *H*, increasing the sustentation afforded by the latter. The lateral tilts of twenty to thirty degrees represent the range of angles at which a disturbing sidewind or irregular gust has its maximum effect to raise one side of the machine and disturb the balance. An attack upon the equilibrium therefore spends itself in turning the machine into a new position against which the attack has less effect than at first, and a limit for the disturbance is quickly found, so far as lateral disturbances are concerned. The tail *C* is formed in two parts which may be joined at the bottom or split apart (the latter giving easier access to the motors or motor). Each of the parts is bounded by triangular surfaces coming together in an oblique sharp edge at the rear, and between them at the top is formed an air trough facilitating the confluence of displaced air at the rear. The under-surfaces of the tail are about horizontal, in the fore-and-aft direction, so that they do not contribute to sustentation unless the machine is tipped backward. In other words, the prow, body and tail are, in conjunction, of a self-righting formation and contribute much to support when the machine is moving forward either by motor power or gravitation, but their susceptibility to disturbance is much smaller than that of an equal area of wing surface, owing to the lateral tilt and the planity of the surfaces. Much of the faulty equilibrium of biplanes, which is due to the high susceptibility to disturbance of the lower plane and of the rudder elements placed far in front and to the rear of the machine, is therefore remedied without much, if any, sacrifice of sustentation per square foot of surface.

The monoplane type of this design is indicated in outline in Figs. 4 and 5. Here the difficulties in obtaining sufficient surface for the weight to be carried are mechanically greater than in the type shown in Figs. 1 and 2, but on the other hand the stability and equilibrium should be improved. The sketches show the bottom angle of the body sharper than it should be in practice and the body too far removed from the plane of the wings. The control system as well as the formation of prow and tail and wings are the same as in the other type. An intermediate type is indicated in dotted lines, representing lower fixed wings of small area and possibly secured by stays. The propeller and the skids are the leading features which remain to be described.

(*To be continued.*)

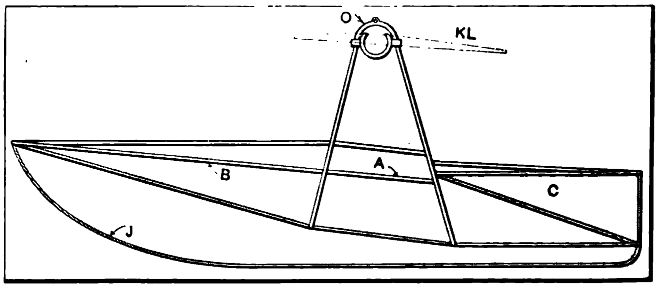

Fig. 5—Diagrammatic side view of monoplane type; all construction deta'ls omitted

Touring in Switzerland

THAT COUNTRY IS RAPIDLY BECOMING THE MOTORIST'S PARADISE. SOME OF THE BEAUTY SPOTS VISITED AT THE ANNUAL MEETING OF THE SWISS CLUB

THERE are more motor parties in Switzerland this season than ever before. Automobile tourists from the United States, England, France, Germany and Austria are numerous in the picturesque fastnesses of the Swiss Alps and in contradistinction to other years, there are few complaints of harsh official action or of bad treatment by the populace.

The Government of Switzerland has secured the endorsement of a uniform road code in twenty-one out of the twenty-two cantons and the agreement of the single outside division is looked for in the near future. The result of the active work of President Empeyta, of the Swiss Automobile Club, and his associates is to be seen in the fact that the high road to the Engadine is now open as far as the village of Chur, while formerly motors were halted at Ragaz.

The Swiss mountain roads have a world-wide reputation, not only for their excellence of construction, but even more largely on account of the superb quality and quantity of the mountain scenery.

Automobile parties may start from half a dozen places in France, Italy and Germany and reach the foot hills of the Alps in a day's journey. Favorite starting points are at Nice, Venice, Lyons and Toulon. From Lucerne, nestling close to the rippling bosom of the mountain lake of the same name, the tourists are within striking distance of the grandest of all European natural scenery.

Lucerne, where Swiss Automobile Club held its meeting (railroad station at left, Mount Pilatus in background)

As is shown in the accompanying illustrations, the lordly peaks of Pilatus rise almost from the edge of the waters, towering into the blue in unspeakable majesty.

There is something unreal and fairylike about the Alpine scenery and an impression of the atmosphere may be gained from these remarkable pictures. At a recent meeting of the Swiss Automobile Club, Lucerne was the starting point from which the club members began their tour of the Burgenstock and Engelburg.

Rivaling the Canadian Selkirks in its precipitous grandeur, the Bergenstock and its surrounding country is so accessible that touring automobilists are able to enjoy its wonders with much facility and lately they have been taking advantage of their opportunities.

The Engelberg, another peak that bears a striking resemblance to Mount Hood in Oregon, save for the fact that Hood stands practically alone, while the Engelberg is surrounded with sister mountains, was one of the points made on the itinerary of the S. A. C. in its recent tour.

There are dozens of other magnificent short trips to be made in the Swiss Alps and at the rate that section is growing in favor with foreign motorists, the time is at hand when with a uniform road code applying to all the cantons, thousands of automobile parties will be attracted.

The more liberal touring laws in Switzerland have served to turn attention strongly toward that section and as a result the Republic has not been the only gainer. The facility with which the tourist may now proceed in that country has given an impulse to traveling by automobile in contiguous territory, particularly as it applies to Americans.

A number of French tours have proved exceedingly attractive as a foretaste to the scenic grandeur and solid enjoyment of culminating pleasure to be found among the Swiss mountains.

Several of these tours, through the wilder and more mountainous portions of that country have been made by Americans in conjunction with more extended travel.

Automobile Club of Winnipeg

STURDY YOUNG ORGANIZATION OF MANITOBA WHICH HAS DONE MUCH TO POPULARIZE THE AUTOMOBILE THERE

WINNIPEG, MAN., Aug. 15—Away up in western-central Canada, where motor vehicles traverse the streets for four months of the year in snow, there is an automobile club with a membership of more than 200, and a policy of progressiveness which might be emulated to advantage in more populous centers. This club flourishes in Winnipeg, Manitoba, the gateway city to the Canadian Northwest.

The thought of motoring in comfort, with a temperature far below zero, to a southern tourist is hardly palatable, but up in Winnipeg they revel in the frosty elements and are as ardent auto enthusiasts as can be found on the continent.

Seven years ago there were but twenty power-propelled vehicles coursing the streets of the Northwestern metropolis and most of these were owned by dealers. A few, however, were held by adventurous business men who joined with the dealers in the formation of an automobile club. The object was to centralize the interests of motorists and to inspire confidence in the conveyance which was afterward to supersede the horse.

Social interests rapidly gained a portion of the club's existence and so rapidly did the automobile business grow that inside of two years special legislation for regulating motor traffic was necessary and the club was active in drawing up this legislation.

From a precarious infancy the club grew rapidly under the management of some of the most capable men of the city, until now, in the strength of its youth, it is accounted one of the best organizations of the kind on the continent and certainly the foremost of Canada. Every question pertaining to the interests of club members is carefully handled by the compact body and at present, although touring and race meetings are occupying a good deal of time, the club is preparing an effort to secure equitable legislation for horse and power vehicles at the next session of the legislature.

It is in the matter of good roads that the club is now most deeply interested. As a factor in building up the highways of the province it has carried the greatest weight. Miles and miles of impassable highways have been turned into good roads by the co-operation of the club with the government and the municipalities. Sign boards giving notice of approaching road difficulties have been erected over many leagues of prairie trail and in some districts the club has at its own expense replaced old wooden road culverts with modern appliances, which do away with many dangerous crossings and make touring more pleasant, not only to motor owners, but all travelers.

The club last year secured and remodeled a club house, 28 miles from the city, to the northwest. A handsome brick building is now equipped with an excellent garage at the rear and has been entirely refitted to meet the requirements of modern motoring. Week end tours to the club are an established feature of the summer season and its patronage during the present month has been so large that extensions are being considered for accommodation. The roads between the city and the club have been particularly well looked after and now less than an hour's spin from the heart of the city will land any ordinary car in the garage at the other end.

The annual club runs have become so popular that it is now proposed to make them semi-annual occurrences. One closed July 5, in which more than 80 autoists participated in a five day run of 507 miles. The distance traversed was not great, but the inspection of the country and the hospitality of the outside points forced the tourists to cut down the distance programme and to return after the tour had been about half completed. It is to complete this run that the members of the club are now proposing to hold a fall tour.

The whole of the west is enthusiastic about the automobile. This year more than 1,000 cars have been disposed of through Winnipeg agencies alone, and of all Western auto centers Winnipeg leads, and the Winnipeg Automobile Club is the parent body of motor owners.

During the past winter almost every car owned in the city was used right through every kind of weather. It was the first winter when motor cars were generally operated. Coupés, limousines and general touring cars with top equipments were run through everything. There was little trouble with frost on the mechanical workings and from the confines of the closed car, traveling was as comfortable as in summer. The members of the club were foremost among the demonstrators of winter possibilities of the automobile. Almost every member of the club drove his car all winter and the few which did remain in the various garages for the most part belonged to owners who were sojourning in other climates.

Among the clubs of the west, the Winnipeg Automobile Club has a very high standing. It is comprised of many of the best men of the city and stands for progressive but not speedy motoring. When the club tours, public receptions are always given by outside points visited and when other clubs tour into Winnipeg, they are royally received by the members of the local club.

The officers of the club are: Patron, Sir Daniel McMillan; honorary president, R. McLeod; president, C. H. Newton; first vice-president, B. D. Sprague; second vice-president, W. L. Parrish; secretary-treasurer, W. E. Wright; executive committee; S. P. Belcher, E. C. Ryan, W. C. Power, F. E. H. Luke, W. R. Bawlf, W. A. T. Sweatman and A. A. Gilroy.

Coming Events

CALENDAR OF FUTURE HAPPENINGS IN THE AUTOMOBILE WORLD THAT WILL HELP THE READER KEEP HIS DATES STRAIGHT—SHOWS, RACES, HILL CLIMBS, ETC.

Dec. 1	Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.
Dec. 31-Jan. 7, '11	New York City, Grand Central Palace, Eleventh Annual International Automobile Show.
Jan. 7-14, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Manufacturers.
Jan. 16-21, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Jan. 28-Feb. 4, '11	Chicago Coliseum, Tenth Annual National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Pleasure Cars and Accessories, Exclusively.
Feb. 6-Feb. 11, '11	Chicago Coliseum, Tenth National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Commercial Vehicles, Pleasure Cars, Motorcycles and Accessories.

Races, Hill Climbs, Etc.

Aug. 16-27	Munsey Tour.
Aug. 19-20	Brighton Beach, L. I., Twenty-four Hour Race.
Aug. 23	Cheyenne, Wyo., Track Meet.
Aug. 26-27	Elgin, Ill., Road Race, Chicago Motor Club of Chicago, Ill.
Aug. 31	Minnesota State Automobile Association's Reliability Run.
Aug. 31-Sept. 8	Kansas City, Mo., Reliability Run, Auto Club of Kansas City.
Sept. 2-5	Indianapolis, Ind., Speedway Meet.
Sept. 3-5	Run and Labor Day Race Meet of North Wildwood Automobile Club.
Sept. 5	Cheyenne, Wyo., Track Meet.
Sept. 5	Denver, Col., Road Race, Denver Motor Club.
Sept. 5	Los Angeles, Cal., Speedway Meet.
Sept. 5-10	Minneapolis, Minn., Track Meet at State Fair.
Sept. 7-10	Buffalo N. Y., Reliability Run, A. C. of Buffalo.
Sept. 9-10	Providence, R. I., Track Meet.
Sept. 10	Los Angeles, Cal., Mount Baldy Road Race.
Sept. 10	San Francisco, Cal., Golden Gate Park Road Race, Automobile Club of San Francisco.
Sept. 10-12	Seattle, Wash., Race Meet.
Sept. 15	Algonquin, Ill., Annual Hill Climb of Chicago Motor Club.
Sept. 16-26	Asbury Park, N. J., Aviation Meet, Aero Club of America.
Sept. 17	Syracuse, N. Y., Track Meet of Automobile Club of Syracuse, Syracuse Automobile Dealers' Association and the New York State Fair Association.
Sept.	Chicago, Commercial Car Reliability Contest of Chicago Automobile Club.
Oct. 1	Long Island Motor Parkway, Vanderbilt Cup Race, Wheatley and Massapequa Sweepstakes.
Oct. 3	Louisville, Ky., Reliability Run, Louisville Automobile Club.
Oct. 6-8	Santa Anna, Cal., Track Meet.
Oct. 7-8	Los Angeles, Cal., Speedway Meet.
Oct. 8	Philadelphia, Fairmount Park Race, Quaker City Motor Club.
Oct. 15	Long Island Motor Parkway, Grand Prize, Automobile Club of America.
Oct. 15-18	Chicago, Ill., Chicago Motor Club's 1,000-Mile Reliability Run.
Oct. 20-22	Atlanta, Ga., Speedway Meet.
Oct. 23	San Francisco, Cal., Road Race, Portola Cup.
Oct. 27-29	Dallas, Tex., Track Meet.
Nov. 5-6	New Orleans, La., Track Meet.
Nov. 6-9-13	San Antonio, Tex., Track Meet.
Nov. 24	Redlands, Cal., Hill Climb.
Nov. 24	Savannah, Ga., Road Race, Savannah Automobile Club.

Foreign Shows and Races

May 1—Oct. 1	Vienna, Austria-Hungary, Automobile and Aviation Exposition.
Aug. 1-Sept. 15	French Industrial Vehicle Trials.
Oct. 15-Nov. 2	Paris, France, Aeronautical Society Show.

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

QUALITY, as it is measured in an automobile, is so deep-seated that it escapes the notice of the average purchaser until he finds out after a period of actual service that the repair bill he has to meet is conspicuously below that which is charged up to his neighbor for repairs to a car of another make.

* * *

WHY is it that the average purchaser seems to think that quality is measured by the color of the paint on the body, or the striping of the wheels, or some other exterior "blemish"? Is it not a common statement "Handsome is as handsome does"?

* * *

WHAT is the proper diagnosis of the disease which fastens its fangs upon the man who insists upon "domino" as the brand of sugar for use in his coffee, but who disregards every consideration for quality when he selects an automobile?

* * *

IS is not a fair inference that defects, if there be any, will be covered up by a "swell" appearance? Does a real tailor ever inflict a "swell" suit of clothing upon the attention of a discriminating man?

* * *

JUMPING to the conclusion that an automobile should be measured by the purchase price is a habit that is devoid of a substantial foundation.

THE wonder is that anyone would be so short-sighted as to believe that the rules which govern wise purchasing of every other commodity should be inefficient when applied to the purchase of an automobile.

* * *

PERHAPS it is not too much to say that the quality of an automobile depends upon appropriateness of design in view of the service to be rendered, character of the materials employed in the construction throughout, and skill of the artisans engaged in the work.

* * *

EVERY automobile that will run and continue to do so without a disgruntling cost of upkeep has quality in its makeup to a marked degree, but it may not be the quality that some particular autoist will enjoy.

* * *

CERTAINLY appropriateness must be measured on a gauge based upon the intended service of the car, without disregarding the service expected by the purchaser.

* * *

IF the roads to be traversed indicate that a transmission gear is a necessity, for instance, to disregard the fact and purchase a car not having this facility is to make a grave mistake.

* * *

NEXT to leaving out the sliding gear entirely is the relatively unwise neglect to provide a sliding gear of the character which utilizes a sufficient number of speed changes to properly serve the purpose.

* * *

SINCE everyone knows that an internal combustion motor is not inherently flexible, and its principles demand that it be run more or less on a constant speed basis, what is the use of disregarding the fact that speed changes must be made through the good office of a sliding gear or some other equally efficient auxiliary device?

* * *

LIKEWISE in the several other particulars, the question of quality must be arrived at; but it will be a fallacy to suppose that this quality is abstract in its character and confined to the car. It is not the quality of the car that a buyer should be sure of, but the quality of the service he wants. An automobile that is good for one thing may be useless for another, and yet the quality of the car *per se* may be on a high plane.

* * *

PROGRESS will probably never be made in the attempt to impart useful information of a mechanical character to the non-mechanical mind until the literary surgeon returns to the earth, eliminates superlatives, confines himself to a single subject for a given occasion, and gives clear reasons for his premises. The average writer, desiring to hold an estimable position among his confrères, disdains to tread in the path of simplicity out of fear of ridicule, and misses the target that he aims at, blinded by the smoke of his own lack of clearness. It is a false pride, with nothing of glamor to be gained, but the penalty is sure—the audience snores.

Selden Decree Filed

U. S. CIRCUIT JUDGE HOUGH ENTERS ORDER AGAINST FORD AND PANHARD, REQUIRING THEM TO FILE HEAVY BONDS PENDING FINAL HEARING. PERPETUAL INJUNCTIONS ISSUED

IN accordance with the substantial ideas expressed in the decree submitted to Federal Judge Hough by attorneys for the A. L. A. M., at Narragansett Pier, July 19, the court has signed decrees in the principal suits under the Selden patent. This action was taken rather unexpectedly last Thursday.

The full text of that tentative decree was published in THE AUTOMOBILE at the time and its terms were sweeping and of such breadth as to form a complete basis for future action. The status of the decree is interlocutory and may not be the last word in the litigation. This is all the more probable because the defendants, the Ford Motor Company and the Panhard Company, will undoubtedly take the cause to the Federal Court of Appeals.

The decree holds the Selden patent to be legal and valid and valuable and declares that the rights of the plaintiff under it have been infringed. An injunction is ordered to restrain the manufacture, use and sale of infringing automobiles. But simultaneously with this action, Judge Hough also filed a memorandum opinion covering the contingency of appeal from the order of court. This opinion states that in case the defendant companies decide to perfect their appeal, the injunction shall be raised upon the filing of a bond of $350,000 by the Ford Company and one of $16,000 by the Panhard. The opinion requires that pending a final hearing in the Court of Appeals, the defendants shall file sworn monthly statements of their business.

The only particular in which the foregoing procedure differs from what was outlined at the hearing held at Narragansett Pier is in the amount of the bonds required of the defendants. It was suggested at that time that the bonds be placed at $500,000 for the Ford Company and $50,000 for the other concern.

The original opinion of Judge Hough was filed in the United States Circuit Court last September. The merits of the case were passed upon substantially as they were in the decree of last Thursday, but owing to the fact that the Columbia Motor Car Company, which had succeeded to the rights of the Electric Vehicle Company as lessee under the Selden patent, had not been made party complainant, it was necessary to substitute that company and the process proved to be rather long drawn out.

Following is the memorandum filed by Judge Hough:

UNITED STATES CIRCUIT COURT, SOUTHERN DISTRICT OF NEW YORK.

Columbia Motor Car Company and George B. Selden, Complainants, vs. C. A. Duerr & Co. et al., O. J. Gude Co., John Wanamaker, et al., André Massenet, et al., Henry Neubauer, et al., Defendants.

On settlement of final decree.

MEMORANDUM.

I.—Upon a fair reading of the entire bill in equity it does not seem to me to be true that the sole cause of action set up in the bill is for joint infringement. In the typical case against the Ford Motor Company the bill as a whole shows distinctly that the Ford Company was engaged in selling within the Southern District of New York through Duerr & Company, and that Duerr & Company were in some way the agents of the principal defendant. The allegations of confederation and conspiracy must be read in conjunction with the basic fact of agency.

Infringement has been found by both defendants on an issue deliberately tendered in defendant's answer which denied infringement by the defendants both jointly and severally. The principal defendant having tendered this issue itself does not seem to me to be in a position now to insist on so narrow a view of the pleadings—a view, however, which apart from the answer I am unable to take.

II.—Without an assignment or transfer made in accordance with the requirements of the various patent acts I do not think that the legal title to a patent passes to a receiver. Undoubtedly he has the equitable title, and he may by equitable process compel an assignment; but it does not appear that this was ever done with respect to the patent in suit. In my opinion the action was originally brought in the name of the proper parties.

III.—Under the established practice in this Circuit I do not think that complainants can insist upon terms of suspending the injunction more severe than this: They should have a bond in the sum sufficient to secure the payment of such a recovery as now seems allowable, and they should also have sworn information furnished monthly of the business transactions during the preceding month in machines infringing under the decision filed herein.

The proper amount to be fixed for this bond is a point which might be much discussed; but such discussion could not be had without revealing the affairs of the defendants in a manner which under the practice I have alluded to seems to me improper. Suffice it to say that comparing the information furnished me by defendants' counsel with the impressions of complainants (as stated in argument) there is a much smaller difference than I expected to find. It is to be remembered that a very large part of either the list or selling price of many, if not most, automobiles includes accessories having no relation to Mr. Selden's patent. Upon the whole I think it would be just to require from the Ford Motor Company a bond, in a form to be settled upon notice if not agreed upon, in the sum of $350,000, and from the Panhard Company a similar bond in the sum of $16,000.

The reports of sales are to be filed with the clerk of the Circuit Court, to be by him deposited in a safe place to which the public shall not have access; notification of the time of filing is to be served on complainants, who shall be entitled to examine the same upon the order of a Judge duly authorized to sit in the Circuit Court of the United States for the Southern District of New York. Upon filing the bonds above described an order may be entered suspending injunction in the cases of the Ford Motor Company and the Panhard Company pending appeal, which order will contain the provisions above indicated in relation to the filing of reports. Final decrees in all of the cases above enumerated are signed and placed in the hands of the clerk this day.

August 11, 1910. C. M. HOUGH, D. J.

(Endorsed) U. S. Circuit Court, Southern District New York. Filed August 11, 1910. John A. Shields, Clerk.

Perpetual injunctions restraining John Wanamaker, Thomas B. Wanamaker, L. Rodman Wanamaker, Robert C. Ogden, The O. J. Gude Company, Henry Neubauer and Albert C. Neubauer from infringing upon the Selden Automobile Patent were issued by the United States Circuit Court for the Southern District of New York on Saturday.

Wanamaker formerly handled the Ford car as a dealer, the Gude Company were users of unlicensed cars, while the Neubauers acted as agents for a line of unlicensed imported cars.

The injunctions were issued under Judge Hough's recent decision and under the provision of the decrees in suits brought against these parties, in which he sustained the Selden Patent, granted the injunctions and also accountings of damages and profits.

The injunctions, which were personally served by U. S. Marshal Henkel on John Wanamaker, the firm of John Wanamaker and the O. J. Gude Company, command all of the defendants as well as their associates, officers and agents under penalties, in case of disobedience, to immediately and until the expiration of the Selden Patent,

> "desist from, directly or indirectly, making or causing to be made, using or causing to be used, or offering or advertising for sale or causing to be offered or advertised for sale or importing or causing to be imported, or selling or causing to be sold to others in any manner, or disposing of in any way within the United States any road engines, vehicles, automobiles, devices or apparatus containing or embodying or employing any of the inventions described in said letters patent and claimed in the said first, second and fifth claims thereof, or substantial or material parts thereof, or from infringing said claims of said letters patent in any way whatsoever."

Under the provisions of these injunctions the parties enjoined cannot directly or indirectly make, offer or advertise for sale, sell, use, import or dispose of any gasoline automobiles in infringement of the Selden Patent, without violating the injunction and being liable to punishment as for contempt of court.

Program at Elgin

FOUR RACES TO BE RUN OFF OVER THE NEW COURSE OF THE CHICAGO MOTOR CLUB ON AUGUST 26-27. ENTRY LIST PROMISES TO BE VERY LARGE

CHICAGO, Aug. 15—The program to be run off over the new course laid out just west of the city of Elgin, August 26-27, under the auspices of the Chicago Motor Club, includes four events. All four are for stock cars under the strict interpretation of the rule. The fields in each of the events will be large and representative, according to the entries so far made. While the list will not be closed until August 20, the present indications point to a total entry of about forty cars.

The course has been repaired and improved with painstaking thoroughness, and at present half a dozen of the entered cars are engaged in daily practice upon it.

The first race is limited to Class B, division 2B, cars having a piston displacement of from 161 to 230 cubic inches. The trophy is called the Fox River Valley emblem, and a typical entry list has been received, which will probably be augmented by several additional contestants. The minimum weight of entrants in this class is fixed at 1,400 pounds. The distance will be sixteen times around the course, which is 8 1-2 miles, or about 135 miles. In addition to the trophy, a purse of $300 will also be awarded to the winner. The Fox River trophy becomes the absolute property of the winning entrant.

The second race is for the Kane County trophy and a similar purse. The cars are those of Class B, division 3B, of 231-300 cubic inches piston displacement. Minimum weight is 1,700 pounds, and the distance, twenty laps of the course, or about 170 miles. This trophy becomes the permanent property of the winner.

The third race, and the final one for the first day's sport, is for cars of Class B, division 4B, 301-450 cubic inches displacement, of a minimum weight of 2,000 pounds, and the distance is twenty-four laps, or about 204 miles. The trophy, which will become the property of the winner, is called the Illinois trophy. In addition the winner will receive $400.

On Saturday, August 27, the only contest carded is the race for the Elgin National trophy. This will be the star event of the meeting and is open to stripped chassis in Class B with a piston displacement of under 600 cubic inches and a minimum weight of 2,300 pounds.

The Elgin National trophy does not become the outright property of the winner, but under the terms of the race it will be held by the winner for one year. But along with the cup will go $1,000 to the successful entrant. The second car will be awarded $300 and the third $200.

The lists do not close until next Saturday night, but already 26 cars are entered, while there are hanging fire enough more to bring the grand total up to at least forty.

As matters stand right now the Chicago Motor Club has a most representative field in, which includes most of the best drivers in this country. In Harroun, Dawson, Grant and Mulford they have four drivers who have won their spurs at long distance racing and whose struggles for the $4,500 trophy in the big race should be worth going miles to see. Hearne is another star who will be in; he will officiate at the wheel of a Benz. Oldfield also will be in the galaxy, while nearly every other man is well known in the racing game.

With everything running smoothly in the entry line, the Motor Club is putting forth its best efforts toward having the course in readiness for the struggles. The contractors have not been doing as well as they expected because of the lack of rain, water being a necessity in order to bind the gravel and clay that have been dumped on the soft spots on the south leg of the course. Because of this delay it will not be possible for the training to begin before Monday hardly, although it was expected the drivers and cars could get to going by the middle of the week. When training does start the men will be allowed the freedom of the circuit from 11 a. m. to 2 p. m. each day, while the racing each day will start at 10 o'clock.

Already most of the teams have engaged quarters at the course, and the Marmon, National, Cino, Lozier, Cole and Falcar are now awaiting the chance to begin training.

The Motor Club has secured the Warner timing apparatus to time the races, the first time this has been had for a road race.

With the exception of the Elgin National Trophy race, all the cars are of 1910 design, with four-cylinder engines. In the big event the Lozier and the Matheson are 1911 models, and the Alco harks back to 1909. The Matheson and the Alco are the only six-cylinder cars. Following is a list of the entries:

FOX RIVER TROPHY

Car	Entrant	Bore	Str.	Driver
Ford	Ford Motor Co.	3¾	4¼	Kulick
Cole	Cole M. C. Co	4	4	Endicott
Staver-Chic.	Staver Car. Co.	4	4	Cheney
Staver-Chic.	Staver Car. Co.	4	4	Monkmeier
Benz				Hearne
KANE COUNTY TROPHY				
Marmon	N. & M. Co.	4	4½	Dawson
Marmon	N. & M. Co.	4	4½	Buck
Cino	Haberer & Co.	4⅜	5	Fritz
Overland	Overland Mot. Co.	4¼	4¼	Schillo
Kisselkar	H. P. Branstetter	4¼	4¼	Endicott
Corbin				Matson
ILLINOIS TROPHY				
National	A. W. Greiner	5	5 11/16	Greiner
National	National Auto. Co.	5	5 11/16	Livingstone
Marmon	N. & M. Co.	4½	5	Harroun
Falcar	Fal Motor Co.	4⅛	5¼	Pearce
Falcar	Fal Motor Co.	4⅛	5¼	Geinaw
Kisselkar	H. P. Branstetter	4⅞	4¾	Schoeneck
Midland	Midland M. Co.	4½	5	Ireland
ELGIN NATIONAL TROPHY				
National	A. W. Greiner	5	5 11/16	Greiner
National	National Auto. Co.	5	5 11/16	Livingstone
Marmon	N. & M. Co.	4½	5	Dawson
Marmon	N. & M. Co.	4½	5	Harroun
Lozier	Lozier Motor Co.	4	5⅜	Mulford
Matheson	Matheson Auto. Co.	4½	5	Reynolds
Alco	American Loco. Co.	4⅘	5⅗	Grant
Simplex	L. A. Shadburne	5¾	5¾	Saynor
Kisselkar	H. P. Branstetter	4⅞	4¾	Schoeneck
Black Crow	Black Mfg. Co.	4 5/16	4⅞	Stinson
Knox Six				Oldfield
Jackson				Schieffler
Simplex				Robertson

Norristown Club to Promote a Track Meet

NORRISTOWN, PA., Aug. 15—The Norristown Automobile Club has arranged a comprehensive program of events for its race meet to be held at the Belmont Driving Club's track, Narberth, on September 24. In addition to the big race of the day, a match race between a Simplex and a Fiat, best two out of three 5-mile heats, the following list is announced:

1—Class B, Division 8, 5 miles, open to any gasoline stock chassis with a piston displacement of 161 to 230 cubic inches.
2—Class B, Division 2, 5 miles, open to any gasoline stock chassis, piston displacement 301 to 450 cubic inches.
3—Class B, Division 5, open to any gasoline stock chassis, piston displacement 451 to 600 cubic inches.
4—Class B, Division 2, 10 miles, open to any gasoline stock chassis, piston displacement 161 to 230 cubic inches.
5—Class B, Division 4, 10 miles, open to any gasoline stock chassis, piston displacement 301 to 450 cubic inches.
6—Class B, Division 5, 10 miles, open to any gasoline stock chassis, piston displacement 451 to 600 cubic inches.
7—Free-for-all handicap, 5 miles, open to cars of all types and motive powers. First prize, $100; second, $50.
8—Free-for-all handicap, 10 miles. Prizes same as in No. 7.
9—One-mile record trials. Prize, cup.
10—Amateur handicap, 5 miles. Prizes, cups to first and second cars.

In the first six events the prizes will be: First, $50; second, $25.

In order to assure accuracy in timing to establish records for the course, the times will be clocked automatically.

Detroit Doings

NEWS OF THE WEEK FROM THE AUTOMOBILE MANUFACTURING CAPITAL OF THE COUNTRY—NEW COMPANIES ORGANIZED AND OLD ONES REORGANIZED; NEW FACTORIES GOING UP; TRADE CHANGES, ETC.

DETROIT, MICH., Aug. 15—Since Jan. 1, the records of the Secretary of State show 92 new motor car and parts companies have been organized in Michigan and nearly 75 per cent. of these are located in Detroit. This is at the rate of three new companies per week. To be more explicit, there were 49 motor car companies and 43 parts companies, and of these Detroit contributed 36 and 30 respectively. The capital stock represented is $6,822,500, of which Detroit's share is $4,503.000. These figures do not include corporations organized previous to Jan. 1, 1910, that have increased their capitalization since that date.

The 36 new motor car companies organized in Detroit during this eight-month period have a combined capitalization of $3,432,000, and many of them are actively engaged in turning out cars. The other 13 companies are distributed as follows: Two in Mt. Clemens and one each in Birmingham, Bad Axe, Port Huron, Kalamazoo, Owosso, Ionia, Gaylord, Alpena, Niles, Ann Arbor and Saginaw. The 30 parts manufacturing concerns organized in this city have a combined capital stock of $1,071,000. Of those outside Detroit, Lansing gets three, Jackson two and Battle Creek, Flint, Ludington, Port Huron, Wyandotte, Muskegon, Hastings and Rochester one each. The outside car makers are credited with a total capitalization of $1,589,500 and the parts makers with a $730,000 investment.

Reorganization of the Anhut Motor Car Co. under the name of the Barnes Motor Car Co., which has been in contemplation several weeks, was effected at a meeting of the stockholders last Friday afternoon. The capitalization is $300,000, of which $225,000 is common and $75,000 preferred stock. William M. Walker will continue as president and will take a more active part in the affairs of the company than formerly. Creditors have granted an extension of 18 months and Mr. Walker hopes to have the business on a solid foundation by the end of that period. For the 1911 trade the company will manufacture a six-cylinder car to sell at $2,250 and a four-cylinder car to sell at $1,400. The reorganized concern takes its name from Henry C. Barnes, the factory superintendent. He was formerly with the Overland Co. Charles E. Henkel is secretary and treasurer of the Barnes Co. There is no change in the directorate.

In the readjustment, Senator John N. Anhut, former president of the company, with whom the officers have had some trouble over the disposition of stock, was left out of consideration. He will no longer have any active connection with the company, it is said. Anhut, whose continued absence from the city has given rise to numerous stories and whose whereabouts have been something of a mystery, has finally been located in Europe. In a letter to a friend he explains that he went away for a rest preliminary to his campaign for re-nomination as State Senator from this district and incidentally to meet his sweetheart. He expects to return home about Sept. 1.

Building permits have been taken out for a $14,000 addition to the Warren Motor Car Co.'s plant, extending the length of the main building, which is two stories high and 60 feet wide, from 280 to 600 feet. This addition, together with two new buildings to be erected by the same company on Holden avenue, between Brooklyn and Lincoln avenues, will more than double its present capacity. The estimated cost of the two new structures is about $27,000, according to the permits.

The Hupp industrial group in the Fairview district is beginning to assume stupendous proportions. The "family circle" now comprises the Hupp-Turner Machine Co., the Hupp-James-Halloran Foundry Co. and the Hupp-Johnson Forge Co., all of which are operating in new buildings. They will be joined presently by the Rotary Valve Motor Co., which is building a six-cylinder car with a new and practical engine, and the Hupp Yeats Co., which is soon to put out an electric coupé. Buildings for the accommodation of these last named concerns are nearing completion. It is the intention later on to provide quarters in the same group for the Hupp-Ellis-Rutley Construction Co. and the Hupp-Detloff Pattern Co. Robert C. Hupp, who is prominently identified with all these companies, holds the title to the land which constitutes the site, comprising 53 acres.

News that Judge Hough had handed down his decree in the Selden patent case failed to create even a ripple of excitement among the officers of the Ford Motor Co. here. Henry Ford betook himself to his country home hours before the battery of reporters and correspondents descended on the plant. In his absence, James Couzens, secretary and treasurer of the Ford Co., talked freely.

"It is a decree that should have been rendered 11 months ago," said he, "but it has taken the Columbia Motor Car Co. that length of time to establish its title to the patent. No injunction will be issued restraining us from manufacturing cars. We have already prepared an appeal to the higher court and in place of the $350,000 bond required we are planning to put up the cold cash. The case has been noticed for hearing some time in October and we are in hopes that it can be disposed of before Christmas. In the meantime the Ford Motor Co. will keep right on turning out cars."

The E-M-F Co. announces the appointment of Charles F. Garaghty as assistant to the treasurer of the company. Mr. Garaghty also will take charge of the repair, parts and claims departments and will have special duties to perform in connection with the commercial department. H. A. Mitchell has tendered his resignation as assistant advertising manager of the Abbott Motor Car Co. to accept a position in the engineering department of the Hudson Motor Car Co.

Oct. 1 is the date set for the beginning of manufacturing operations in the Lozier Motor Co.'s mammoth Detroit plant. After that date complete cars will be turned out only in the local factory, it is announced, while the Plattsburg, N. Y., plant will specialize on parts.

Charles E. Baker, Charles H. Gowin and Charles J. Stokes, all of Cheboygan, Mich., have formed the Warren-Detroit Garage & Sales Company and took over the garage and salesroom at 736-740 Woodward avenue, formerly occupied as the local sales branch of the Winton Company. They will be State distributors for the Warren-Detroit "30."

Plans are about completed for the two-story garage and salesroom to be erected for the Michigan Buick Auto Company on Woodward avenue. The building will be of brick and stone.

The Michigan Motor Car Manufacturing Company, at a recent meeting, decided to increase its capital stock to $100,000.

Another new corporation that will soon make its bow is the Detroit Airless Tire & Rubber Company. The organization plans have been under way for several weeks and are now nearing completion. The persons interested have been making airless tires on a small scale in Dayton, O., but the enterprise will be removed to this city as soon as the present plans are perfected.

The newly-organized Lion Motor Sales Company filed articles of association with the Wayne county clerk Wednesday. Fred Postal, proprietor of the Griswold House, holds all but two shares of the capital stock of $10,000, all of which has been paid in. The holders of the other two shares are Robert L. Fee and Harry F. Postal.

Omaha's First Home-Built Car Arrives

Omaha, Neb., Aug. 15—The first Omaha manufactured motor cars were put on the market last week and one or two are already being driven around the streets of this city. They are products of the Rogers Motor Car Company. The new car is designed for business purposes and is in the line of a delivery wagon. Driving on rough country roads has been kept in view by the manufacturers and the employment of a flexible wood frame, a novel type of transmission and scientific adjustment of springs, has produced a vehicle which is wonderfully easy riding and which works remarkably smooth with hard tires. The Rogers Company has a factory with a capacity of 500 cars a year and this will be the output for 1911.

Auto row in Omaha is undergoing a transformation by reason of the recent additions to the ranks of the auto dealers and agencies. Among the recent acquisitions are the handsome new garages of the Van Brunt Automobile Company, the Maxwell-Briscoe branch, the Stanley steamer, the Paxton Mitchell, the Cadillac Company of Omaha and the partially completed building of the Ford branch. The E-M-F which has a branch here is expected to open shortly in its handsome new home.

Syracuse Club Guards Tourists

Syracuse, N. Y., Aug. 15—The Automobile Club of Syracuse has set an example for similar organizations the country over, in safeguarding motor tourists and the general driving public. Upon the West Camillus hill near this city, one of the most dangerous in the State, they have a warning sign for day and night, as it is equipped with a lantern, as shown in the accompanying illustration. The sign is at the foot of the first gradual descent, coming east toward Syracuse, and near the first bad right hand curve. The hill is three-quarters of a mile long and full of twists and turns. An automobilist was killed upon it through his machine being ditched three years ago and there have been many accidents resulting in injuries. The hill is a part of the main highway across the State and is traversed by numberless tourists.

For several years the Syracuse club had the hill boarded, but because of the increased travel of tourists, the officers hit upon this novel scheme. The sign is of cement stone, built by the club, and the light is arranged so as to show a green glare clear from the top of the hill. The headlights of the cars shine directly upon the lettering as the machines come toward it, and if they are not lighted a white light from the lantern serves the purpose.

North of this sign there is another branch of the road running toward Warners, and upon this branch a red light serves to warn tourists of the hill. The club engages a man the year round to care for the sign, replenishing and lighting the lanterns, etc.

Stone warning sign erected on bad hill by Syracuse clubmen

S.A.E. Membership Nearing 400 Mark

The Society of Automobile Engineers membership will soon pass the 400 mark. The following members and associates were elected last week: Thomas W. Warner (Warner Mfg. Co.), Frank H. Trego (Hudson Motor Car Co.), Elliott J. Stoddard, Detroit, Mich., W. Rexford Smith (Warner Mfg. Co.), Charles F. Splitdorf, New York City, Alfred J. Poole, New York City, Matthew B. Morgan (Chalmers Motor Co.), James McIntosh (Hercules Motor Truck & Car Co.), Harry Le Van Horning (Waukesha Motor Co.), F. G. Hughes (Driggs-Seabury Ordinance Corp.), O. C. Friend (Mitchell Lewis Motor Co.), F. C. Frank (General Motors Co.), George Dorris (Dorris Motor Car Co.), John Demmler (Clark Power Wagon Co.), Arthur Dugrey (Holly Bros. Co.), Hugh Chalmers (Chalmers Motor Co.), Eugene P. Batzell (Speedwell Motor Car Co.), Guido G. Behn (Hudson Motor Car Co.), Joseph K. White (French Steel Products Co.), Charles D. Shain, New York City, H. J. Porter (J. S. Bretz Co.), Duncan McConnell (Lovell-McConnell Mfg. Co.), Kenneth B. MacDonald (E. R. Thomas Motor Co.), Charles W. Hatch (Perfection Spring Co.), J. H. Friedenwald, Baltimore, Md., John Craig (Standard Metalwork Co.), Harry G. Baldwin (W. A. Wood Mfg. Co.), Noble C. Banks (Gear Grinding Machine Co.), William M. Barr (Lumen Bearing Co.), R. Frank Bower (Bower Roller Bearing Co.), Benjamin Byron Bachman (The Autocar Co.).

Cannot Exact Inspection Fees for Factory Gasoline

Milwaukee, Wis., Aug. 15—The Thomas B. Jeffery Co. of Kenosha, Wis., maker of the Rambler, has won the case brought by the state inspector of oils of Wisconsin, involving the right of the inspector to inspect the gasoline purchased by the motor car company. The municipal court at Kenosha decided that the State cannot force inspection of oil when it is brought into the State and used for the purposes of a concern like the Jeffery company. The limit of apppeal has now expired, which makes the Jeffery victory complete, as no appeal has been made by the inspector. The Kenosha concern buys large quantities of gasoline annually and refused to permit the inspector to inspect it and charge the usual fee because the gasoline is not placed on sale but reserved for its own use. The inspector brought suit to collect the fees. Several cases involving the constitutionality of the law have been brought in other courts of Wisconsin and all are at variance with each other. The Supreme Court has had no opportunity to rule upon it, the nearest approach being this case at Kenosha, which is now closed by the failure to appeal within the prescribed time.

Cullings from Cleveland Motor Field

Cleveland, Aug. 15—The Consolidated Motor Car Company, of Cleveland, $4,000,000 capital stock, to manufacture automobiles, etc., was incorporated recently by G. A. Howells, L. R. Canfield, Thomas D. Russell, J. L. Bradley and Ralph Blue. The capital stock is in equal shares of common and preferred. The incorporators are Cleveland business men and attorneys. The concern will be one of the largest in the city, it is stated, and it is expected that ground will be broken for the factory building in or near the city at an early date.

The stockholders of the Goodyear Tire & Rubber Company, of Akron, held a special meeting Monday and confirmed the report of the directors to increase the capital stock from $2,000,000 to $6,000,000. The increase will be entirely in the common stock. The directors offer the stockholders for 10 days the right to subscribe for $500,000 preferred stock and $250,000 common, but the stock not taken up at that time will be offered to the public. The directors declared a cash dividend of 12 per cent. and 100 per cent. stock out of the surplus earnings to the common stockholders and to provide for the funds necessary to take care of extensions now being made to the plant so as not to impair working capital.

Jersey Motorists Given a Chance in Bay State

Boston, Mass., Aug. 13—To enable New Jersey motorists who are in the White mountains to cross the Bay State without being arrested, and also to enable those about to cross Massachusetts on the way north to go through all right, the Massachusetts highway commission has authorized the various police chiefs in Springfield, Pittsfield, North Attleboro, Lowell, Newburyport and Greenfield to issue licenses to the visitors and collect the fees so that a trip to Boston may not be necessary. A number of New Jersey motorists have been arrested in Massachusetts for not being registered in the Bay State, and some of them stated that they were on the way to Boston to register their cars and that it was not fair to hold them up. It was decided by the commission that it would be only fair to give the visitors a chance and so the police chiefs will do the work.

San Francisco Dealers Organize

San Francisco, Aug. 10—The effort to organize a Motor Car Dealers' Association in San Francisco appears to be meeting with some success, notwithstanding the discouraging experience of last month. At the meeting held July 21 new officers were elected, as follows: J. A. Marsh, president; Cuyler Lee, vice-president; C. S. Richardson, secretary; and I. J. Morse, treasurer. The board of directors is composed of E. P. Brinegar, H. L. Owesney, J. W. Leavitt, W. L. Hughson and A. E. Hunter. The failure of the former effort was largely due to differences of opinion as to admitting the accessory dealers into the organization. The new association is composed entirely of dealers, agents and factory representatives, the accessory trade being excluded. The second meeting, at which the constitution and by-laws were submitted, was held last Monday noon, when good progress was made toward getting the organization on a permanent basis, and the local dealers feel assured that this time they will be able to accomplish something definite through united action.

Fifty Entries for Omaha "World-Herald" Run

Omaha, Neb., Aug. 15—Fifty entries are assured in the *World-Herald* endurance automobile run which is scheduled for August 24-26 through western Iowa and eastern Nebraska. While the Omaha Motor Club, under whose auspices the run will be made, has not formally affiliated itself with the A. A. A., the run will be given under the sanction of that organization.

Five trophies are to be awarded: The grand prize silver trophy by the Omaha *World-Herald* for the car having the best score; a second prize by the Omaha Motor Club for the second best score and three other trophies in each of the three classes.

The cars are divided into the following classes: First, cars selling for $800 or less; second, cars selling for $801 to $1,600; third, cars selling above $1,600. Cars in the first class will travel at an average rate of speed of sixteen miles an hour; second class, eighteen miles an hour; third class, twenty miles an hour. Otto Nestman is in direct charge of the run.

The first day's run is over into Iowa, lunch at Shenandoah, back through Nebraska City to the night control at Lincoln. The second day's run is from Lincoln to Kearny with the noon control at Hastings. The third day's run is back to Omaha by way of Columbus, noon control, and Fremont, the longest day's run.

Quakers Plan Another "Sociability"

Philadelphia, Aug. 15—F. J. Shoyer, chairman of the Ocean Front Association, Ocean City, N. J., has completed arrangements with the Quaker City Motor Club for the latter's sociability run on September 3 from Philadelphia to Ocean City. The run will leave the Hotel Walton, Philadelphia, and end at the Hotel Normandie, Ocean City. Secretary Harbach, of the Q. C. M. C., will issue entry blanks in a day or two and is confident there will be fully 100 cars in line.

Worcester Club's First Track Meet a Success

Worcester, Mass., Aug. 15—The first track meet conducted by the Worcester Automobile Club was successfully run off last Thursday. A big crowd was present at the Greendale half-mile course. John P. Coghlin, former president of the club, acted as referee. The summaries:

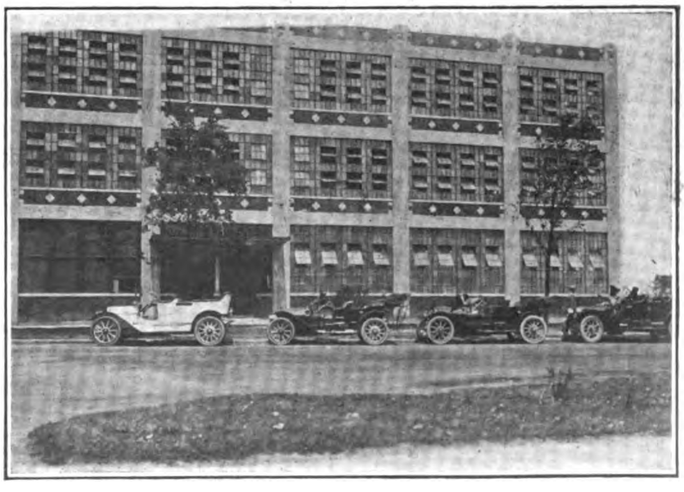
No.	Car	Handicap	Driver	Time
One-Mile Trial Against Time for Half-Mile Track				
1	Benz		Barney Oldfield	1:09 4-5
2	Chalmers 40 (Bluebird)		Louis Strang	1:20 2-5
3	Hupmobile		George Largess	1:56 2-5
Two-Mile Trials Against Time for Half-Mile Track				
1	Darracq		Ben Kerscher	2:25 1-5
Two-Mile Stock Chassis, 161 Cubic Inches and Under				
1	Hupmobile		George Largess	4:09 4-5
2	Hupmobile		Harry Orrendorf	4:11 3-5
Three-Mile Stock Chassis, 301 to 450 Cubic Inches				
1	Chalmers 40		H. C. Grant	4:06 2-5
Five-Mile Stock Chassis, 600 Cubic Inches				
1	Knox "60"		Barney Oldfield	6:52 1-5
2	Chalmers 40 (Bluebird)		Louis Strang	6:53 1-5
3	Chalmers 40		Harry Orrendorf	6:54 3-5
Three-Mile, Free-for-All Handicap				
1	Chalmers 40	17 seconds	Harry Orrendorf	4:11 3-5
2	Knox 60	Scratch	Barney Oldfield	4:11 4-5
3	Chalmers 40	12 seconds	Louis Strang	4:12 1-5
4	Hupmobile	50 seconds	George Largess	5:02
Three-Mile Handicap, Stock Chassis, 600 Cubic Inches				
1	Chalmers 40	40 seconds	Harry Orrendorf	4:50 1-5
2	Chalmers 40 (Bluebird)	35 seconds	Louis Strang	4:50 3-5
3	Knox 60	10 seconds	Barney Oldfield	4:51
4	Hupmobile	70 seconds	George Largess	5:14
5	Darracq*	Scratch	Ben Kerscher	
* Gave up after first mile; engine working badly.				
Special Match Event, 3-mile Pursuit Race				
1	Chalmers 40 (Bluebird)		Louis Strang	4:06 2-5
2	Chalmers 40		Harry Orrendorf	4:26

More Entries for Vanderbilt Cup

According to W. K. Vanderbilt, Jr., president of the Motor Cups Holding Company, there is a strong probability of thirty starters in the Vanderbilt Cup race this year. Among the latest cars to enter are the Roebling-Planche, a new automobile which has four 7-inch cylinders; two Nationals and a Simplex "50."

Wrong Caption Under the Right Picture

In The Automobile of August 4, in the leading article on the annual meeting of the Society of Automobile Engineers at Detroit, there was printed a picture of the new factory of the Gear Grinding Machine Company in that city, but through some error the wrong caption was placed beneath it. We present herewith a partial view of the company's perfectly equipped plant, confident that none of the many who visited it during the convention could have afterward made a mistake as to the identity of the building, despite the misleading caption.



Factory of the Gear Grinding Machine Company, of Detroit

In the Realm of the Makers

E. M. Benford announces that he will enlarge his spark plug factory on Pearl street, Mount Vernon, N. Y., this fall.

The Peck Motor Car Company, 324-26 No. Delaware street, Indianapolis, announces new lines for the season of 1911. They will handle the "Great Western 40" and the Halladay lines.

The De Luxe Motor Vehicle Company, of Cleveland, was incorporated with a capital of $100,000 to manufacture and sell all kinds of motor vehicles. W. G. Moore and others were the incorporators.

A two-story and basement building will be erected for the Fisk Rubber Company at 2210-12 Farnam street, Omaha, the building to cost $15,000. The Fisk Company takes the structure on a long time lease.

The Gaeth Motor Car Company, of Cleveland, has been incorporated with a capital of $400,000 to manufacture and sell motor-propelled vehicles. The incorporators are George S. Patterson, H. A. Stahl, E. J. Thobader, P. C. Carroll and C. P. Gailey.

The Banker Windshield Company, which has been located for years in the Banker Building at Baum and Beatty streets, East End, Pittsburgh, Pa., has moved to the manufacturing plant at Ellsworth avenue and Summerlea street, now occupied by the Pittsburgh Motor Vehicle Company.

The Valve Seating Tool Company has recently been incorporated in Connecticut for the manufacture and sale of a complete line of portable electric drill and hand valve seating tools. Also a combination tool which both oscillates and rotates, so that it can be used for seating valves or drilling, grinding or polishing and as special equipment is fitted with a flexible shaft for valve seating or drilling in inaccessible places.

E. W. Nicholson, formerly with the Midland Motor Company of Moline, Ill., has accepted a position in the sales department of the H. H. Franklin Mfg. Co., Syracuse, N. Y.

The Chamber of Commerce of Akron has taken up the matter of securing the location of the Akron Selle Company, which proposes to erect a large plant for the manufacture of motor trucks and automobile appliances.

Edward C. and Nicholas W. Rassell, of Toledo have organized the E. C. Rassell Company, and will engage in the manufacture of auto trucks in that city. A site has been chosen at Lagrange street on the Michigan Central Belt. The new concern has a capital stock of $25,000.

A new factory for the manufacture of Stroud carbureters has been installed in the building owned by the Electric Vehicle Company, Minneapolis. Work has been started on orders already placed. Mr. Stroud will soon leave for the East for the purpose of demonstrating the merits of the device and to close for distributing rights.

The Toledo Time Test Tire Company has been incorporated by Eugene H. Winkworth, Frank W. Coughlin, Frank B. Miller, Harry W. Eisenberg and Charles Weirich. It has an authorized capital stock of $10,000. The company will manufacture and inflate pneumatic tires, using a patent process, the invention of a Toledo man.

The Stewart & Clark Manufacturing Company has completed its big new addition to the plant, 110 feet front, three story and basement, and 50,000 square feet floor space, which will increase the facilities, and provide for much larger output. The new plant will have a specially equipped department for the manufacture of the Stewart Standards.

The Sheldon Axle Company of Wilkes-Barre, Pa., has opened offices at 68 East 12th street, Chicago. S. B. Russell will be in charge.

George F. Bishop, of the White Company, has bought a half interest in the New Kensington Motor Company of New Kensington, Pa., and will hereafter be its manager.

W. S. Hathaway, district sales manager of the Maxwell-Briscoe Motor Company in the Southwest, has been appointed general supervisor of all branch houses for the Western district of the United States Motor Company.

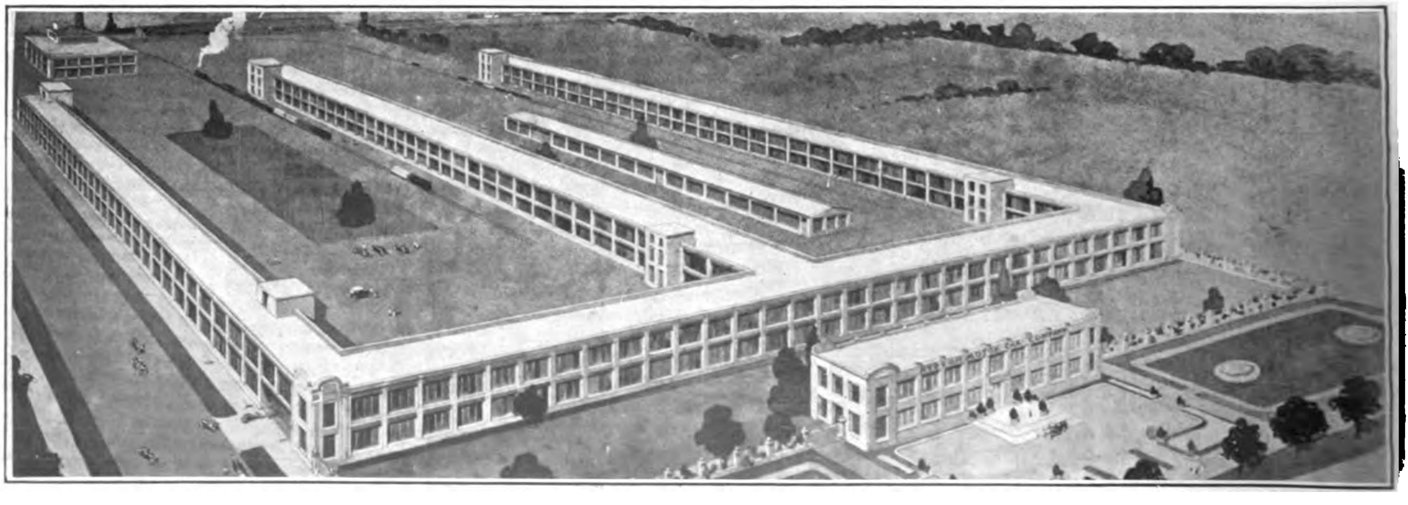
Joseph Tracy, who was appointed on the board of examiners for chauffeurs in the New York City district under the Callan law, has resigned his position. Mr. Tracy said that pressure of other business necessitated this move.

Governor Weeks, of Connecticut, has appointed State Highway Commissioner James H. MacDonald a delegate to the second annual convention of the International Congress of Road Builders at Brussels, Belgium, July 31 to August 10.

Pres. George J. Dunham, of the Royal Tourist Company, and Archie MacLachlan, one of the factory experts, have been visiting the Eastern agencies, spending the greater part of the time in Boston, which was formerly Mr. Dunham's home.

Martin D. Pulcher, purchasing agent and secretary of the Oakland Motor Car Company ever since the company was formed three years ago, has resigned in order to take up the position of general manager of the Bailey Motor Truck Company, in Detroit.

S. H. Humphrey, superintendent of the Brush Runabout Company, has been promoted to factory manager. Mr. Humphrey has been unusually successful in increasing the output of Brush runabouts this year. Before going into the Brush organization he was connected with the Peerless Motor Car Company, of Cleveland.



Bird's-eye view of the new Hudson factory in Detroit, which, including main building, testing building, shipping building, power house and office building, will cost $500,000. It will be completed next month. The buildings are of reinforced concrete and are strictly fire-proof

Agency and Garage News

Charles T. Bowdoin has secured the Pittsburgh agency for the Baker Electric car and is located at the Morewood garage in Centre Avenue.

Joseph A. Henning, who handles the Buick, is having a busy season in his garage and salesrooms, in North Third Avenue, Mount Vernon, N. Y., which he he enlarged this spring.

S. M. Ament, formerly with the Broadway Automobile Company at Seattle, Wash., has joined the force of the M. S. Brigham Motor Car Company in the same city and will sell Cadillac cars.

The ranks of Minneapolis accessory men were increased by one last week when George H. Payne opened offices at 1202 Hennepin Avenue for the distribution of spark plugs and steam vulcanizers. It is his intention to add other lines soon.

The Kissel Kar Company, of Cleveland, was incorporated with an authorized capital of $10,000 to operate a sales agency and repair shop with a garage in Cleveland. The incorporators are E. H. Butt, A. Lezens, E. E. Gott, H. E. Gott and W. B. Davis.

The Automobile and Supply Company, of Akron, was incorporated with a capital of $10,000 by Carl Looker, R. S. Grant, B. Bastian, Amos H. Endeback and J. H. Adams to conduct a general automobile business and to teach people to operate motor cars.

The J. R. Whitney Auto Sales Company of Cleveland was incorporated with an authorized capital of $10,000, to operate a sales agency and garage. The incorporators were J. R. Whitney, W. C. Sell, D. Irene Burke, C. J. Burke and William H. Kemmerling.

N. W. Church, representative of the Stoddard Motor Car Company, reached San Francisco a few days since and will remain there until the Stoddard-Dayton agency change in that territory is settled. He intimates that the company may decide to establish a branch house there.

The Miller Rubber Company of Akron, Ohio, has opened a branch in Detroit, Mich. H. L. Cooper will be in charge.

B. R. Hayden, formerly with the Studebakers at Sacramento, Cal., has accepted a position with the Howard Automobile Company, San Francisco.

G. E. and H. J. Habich Company, Boston, Mass., have been chosen agents for the Hart-Kraft motor trucks and light delivery wagons.

H. E. Smith, proprietor of the Erie Garage at Sheboygan, Wis., has been appointed district agent for the Matheson by Bird-Sykes Co., 1470 Michigan avenue, Chicago, Western representatives.

The Early Motor Car Company of Columbus has taken the Central Ohio agency for the Chase motor truck. The territory covered consists of about 25 counties in the central part of the state.

The Hupp Motor Sales Company, of Cleveland, was incorporated with an authorized capital of $15,000 to conduct a sales agency and repair business. The incorporators are James A. Farrell, William J. Coughlin, Thomas Coughlin, A. C. Ward and W. J. Douley.

J. T. Bill & Co., automobile supply dealers at Los Angeles, who opened a branch store in San Francisco several months ago, are enlarging their stock of accessories, etc., at both stores. The Los Angeles store is now being moved into larger quarters in the same building on Main Street.

John H. Valentine, formerly manager of the Amos-Peirce Automobile Company at Syracuse, has resigned and will enter the automobile business for himself. He has secured the Syracuse agency for the Chalmers cars. He says he will erect a fine garage. For the present he is at 410 West Onondaga Street.

S. G. Chapman reports the arrival of his first shipment of Owen automobiles in San Francisco. Mr. Chapman will look after the interests of the new line in Northern and Central California.

George W. Chandler, of Milwaukee, Wis., has been granted a permit to build a $20,000 garage and stable building at 298-300 Fifth street, Milwaukee. The structure has ground dimensions of 50 by 150 feet and will be three stories high.

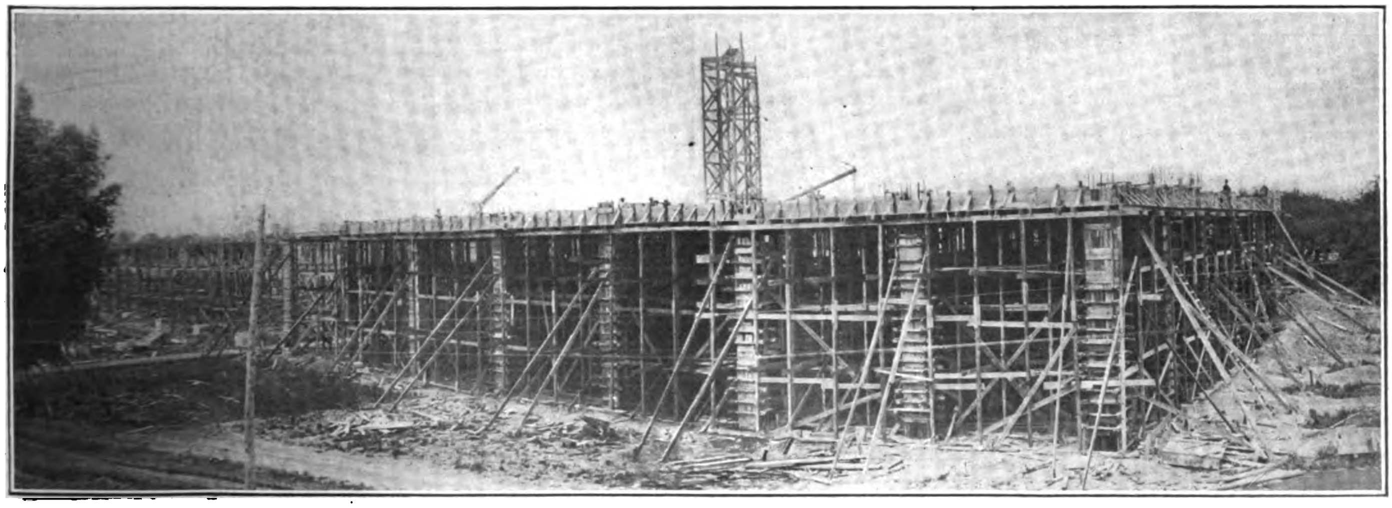
A motor exposition on a small scale, designed to attract the attention of rural visitors, who comprise the bulk of patronage, is to be one of the features of the 1910 Wisconsin State Fair, Sept. 12 to 16.

The Ambridge (Pa.) Auto Company has rented the Jenny Building and opened a first-class garage in that town. The company is composed of John Davie of Ambridge and B. D. McCullough of Tarentum, Pa.

Fire Commissioner Rhinelander Waldo, of New York City, and Commissioner Waldo, First Deputy in Brooklyn, have taken delivery of two 45-horsepower Briarcliff model Lozier cars for use in department work.

The Haines Auto Sales Company, which recently occupied fine new quarters in Los Angeles and which will soon be in its new building in San Francisco, has announced plans for the erection of new buildings at Sacramento and Stockton, Cal., and at Reno, Nevada.

A. G. Williams, who has been associated with the Franklin and C. Arthur Benjamin for several years, has taken a position with the Haynes Automobile Company, of New York, with headquarters in New York, to represent them in New York, New Jersey and New England States, having charge of the wholesale and agency end of the business.

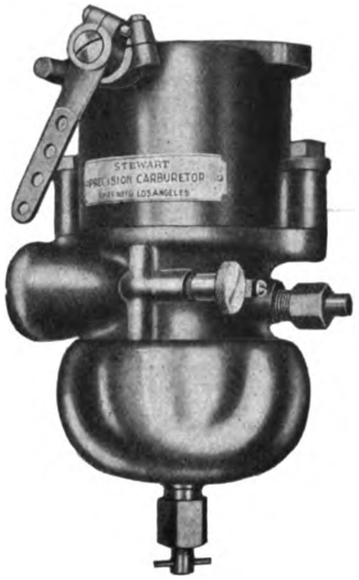


A view of the new reinforced-concrete factory of the Lozier Motor Company in process of erection at Detroit, Mich. Work was commenced on this mammoth plant in May, and it is expected that the factory will be in full operation by October 1st of the present year

Prominent Automobile Accessories

A STURDY CARBURETER

Without springs, and with but one moving part—the air-valve—the Stewart Precision Carbureter, made by the Alfred C. Stewart Machine Works, 1008 Santee street, Los Angeles, Cal., is based on a sound principle—the avoidance of fruitful sources of trouble by a reduction to a minimum of the number of component parts. The proportioning of air and gasoline is accomplished by means of gravity acting on the one moving part. No variation in the gasoline level can change the regulation of the mixture. True proportioning and perfect atomizing of the mixture enable the engine to pull strongly and smoothly, and the vacuum is practically the same at all speeds, being due only to the weight of the spraying valve, which is a constant quantity. The principle upon which this carbureter is operated makes it impossible for it to be affected beyond the minimum by variations of altitude, trips to 7000 feet having been made without adjustment being necessary to produce a well-proportioned mixture.

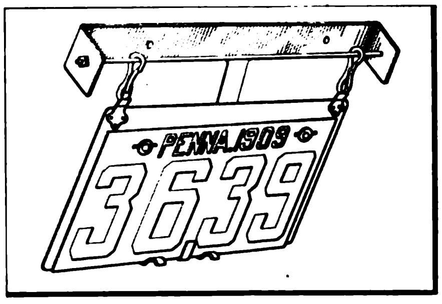


Few parts in this carbureter

MATCH THAT RESEMBLES A GUN

Lighting-up time on a windy night—even if one hasn't forgotten the matches—is a period of much exasperation and no little profanity. Possibly with a view to conserving the future spiritual prospects of its clientéle, but anyhow with an eye open to the positive demands of the present, from the viewpoint of the autoist, the Ronson Specialty Company, 7-15 Mulberry Street, Newark, N. J., has patented and is marketing the Ronson Pist-o-Liter, a device with which it is possible to positively ignite the gas flowing from an acetylene lamp burner, under any and all conditions of wind and weather. It is shaped like a small revolver, and pressure upon the trigger produces an active series of sparks, which will ignite immediately any inflammable gas, which makes the device a handy thing to have around the house as well as in one's car. After discharging, pressure upon the plunger in front of the trigger re-engages the latter for the next "shot." When, after constant use, the sparks become fewer, one or two turns to the sighter cap should be given, to tighten it. At intervals it is also necessary to remove the cap and change the position of the flint, to insure a full series of sparks.

Handy for a windy night



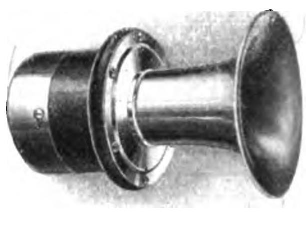
Saves trouble at inter-State ferries

AN AID TO CLEAN GASOLINE

Water and sediment in gasoline are troublemakers for the autoist, and any device which will do away with this evil entirely will be hailed as an unmixed blessing by the motoring fraternity. The Liggett Spring & Axle Company, Park Building, Pittsburg, Pa., after much experimenting, has perfected a gasoline separator for which many claims of excellence are made. Even the highest grade of gasoline contains foreign substances, and the sweating of the tank due to atmospheric conditions frequently adds water to the gasoline, and then comes the trouble of testing batteries, etc., in the effort to locate the trouble. It is claimed for the Liggett Separator that it prevents everything but gas-making fluid from getting into the carbureter. All foreign matter stops at the diaphragm, and is drained off through a petcock.

SMALL, POWERFUL ELECTRIC HORN

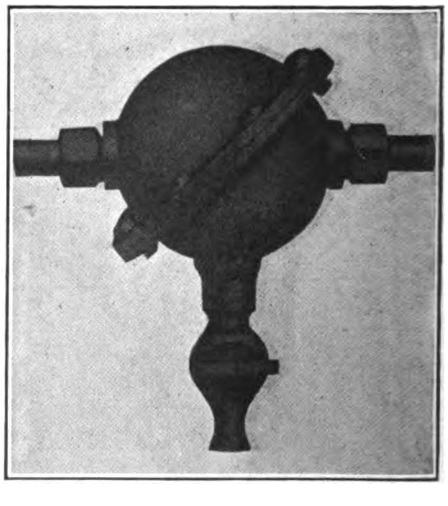
To meet the demand for an electric horn which combines a powerful tone with substantial construction and pleasing appearance at a reasonable cost, the Atwater Kent Mfg. Works, 45 North Sixth street, Phila., has produced the type D Monoplex. It has an improved vibrating system, which is louder and heavier in tone than the one formerly used. Another feature is the one-piece polished brass horn in which there are no soldered seams. This horn is thoroughly substantial and efficient, and may be used on large cars for city use, or on the average car for general use. It consumes little current and gives best results on six dry cells or an eight-volt storage battery. It is small in size only and does not cheapen the appearance of the car on which it is installed.



Small, but far-reaching horn

HANDY REVERSIBLE TAG HOLDER

Little troubles are often the most annoying, mainly for the reason that they are seldom guarded against. The Schell Reversible License Tag Holder, for which a patent has been asked by the Northern Machine Company, Twentieth and Dauphin streets, Philadelphia, will neutralize in large measure the annoyance and delay occasioned at inter-state ferries or boundary lines when the motorist must change his tags in accordance with the laws of the commonwealth he is about to enter. This holder consists of a frame to either side of which a tag can be fastened. The frame itself swings by a pair of spring snaps.



Takes dirt and water out of gasoline

VOL. XXIII NEW YORK—THURSDAY, AUGUST 25, 1910—CHICAGO No. 8

THE AUTOMOBILE

Perfect Scores May Be Numerous in the Munsey Run

BETHLEHEM, N. H., Aug. 20—With less than one-half of the scheduled distance covered, the Munsey Historic Tour of 1910 has already demonstrated everything that such a tour is supposed to show. It has so far proved a sharp test for the cars engaged; a severe trial of the drivers' skill; enjoyable alike to passengers, newspapermen, amateurs and professionals, and it has proved of some educational value, because nearly everywhere along the line where stops were made there was an insistent demand on the part of the public for information about the tour, the automobiles engaged in it and about the utility of the motor and its present status.

An immense public interest is everywhere apparent, and it is surprising to note how many persons along the route are equipped with lists of contestants and the details of the cars. Save for the city of Providence, R. I., the tourists have been treated with distinguished consideration everywhere. They were usually welcomed with open arms and seemed to be regarded as guests whose presence was desirable and profitable.

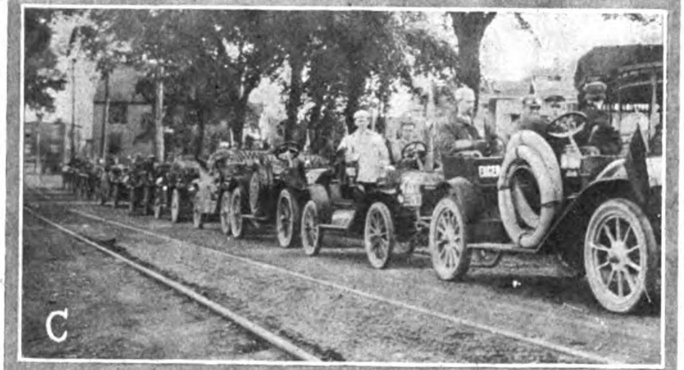
NOON CONTROL AT PROVIDENCE

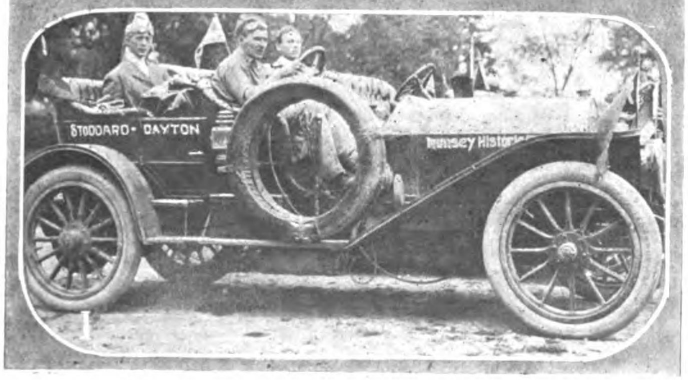
At West Point Monument

As to the latter item, a careful canvass of the situation shows that the caravan leaves behind it at least $1,000 each day. Some of the estimates run as high as $1,500, but the first figure is nearer the truth. Nine cars have been penalized to date, showing that the course has been by no means easy.

Referee Ferguson's system of scoring has proved remarkably efficient and on only one day has the bulletin been delayed until as late as eight o'clock. That was at New London last Wednesday night, when it was posted about that hour.

The coming week will witness several difficult problems being presented to the cars. One





A—Checking out of the noon control at Providence
C—On the outskirts of the city of Portsmouth
E—Where the cars were parked overnight at West Point
G—Staver-Chicago, No. 23, checking out at West Point
I—Leo Shaab and his Stoddard-Dayton, No. 24, at West Point

day the route is to be over 200 miles long and on another it will be over what is regarded by many persons as the worst road in the United States. How the cars will answer these questions, time only can show.

Second Day

New London, Conn., Aug. 17—Several of the cars contesting in the Munsey Historic Tour were penalized as the result of the second day's run, which was from West Point, N. Y., to this city, a distance of 167.8 miles. For the most part the roads were good, but here and there along the route there were stretches of highway that tried the mechanism of the cars severely. This was particularly true of the course ten miles west of Willimantic, after crossing the summit of the hills.

Passing through New Britain, where the Corbin car is manufactured, the whole town turned out to welcome the representative of that factory that is competing in the tour. The Corbin, No. 11, was cheered from the time it entered town until the city limits were reached.

When the tour reached Hartford the scene was repeated with the big yellow Columbia, No. 2, in the stellar rôle.

The day's run was somewhat longer than that of yesterday and was slightly increased in mileage by reason of the fact that the roads selected for the route near New Britain were under repair and a detour had to be made. The smaller cars seemed to do exceptionally fine work during the second day and the whole caravan reported at this city within the time limit. At Waterbury, Conn., the noon control, the officials of the tour were given a warm reception by a committee of citizens and were entertained at the Hotel Elton during the brief stay. Car No. 10, Warren-Detroit, suffered four demerits for working on an adjustment of the carbureter, and car No. 21, the Ohio entry, was penalized a number of points for repairing a leak in the gasoline feed. The exact number of points involved in this penalization will be announced later.

Third Day

Boston, Aug. 18—The third day of the Munsey run was short in mileage, high in interest and long on discomfort. The tourists enjoyed a fine night's rest at New London and everybody was

ready for an early start. Two more perfect scores were spoiled as the result of the day's run, as the Great Western, 18, was given two black marks for repairing a terminal in its ignition system and the Moon, 32, was assessed one demerit for clearing its quadrant lever of sand.

The Pierce-Racine, which traveled into New London on three cylinders, went through the day in apparently normal condition and without penalty. The Inter-State had only the high and intermediate gears in working shape, but checked in on time and without further penalty. The reverse and the low are still out of commission, but will probably be attended to to-morrow.

Everything was pleasant, the road, weather and the going at the start of the day's run, and not a cloud shadowed the general situation until after the cars left Narragansett Pier. Then things began to happen fast, for the E-M-F pilot car came to grief a little way beyond the pier, when in turning out to avoid a bunch of polo ponies, the car struck a tree and bent its front axle. Entering Providence, a special speed trap had been set for the tourists and the first one caught was the Brush runabout, 13; next Starter Newmyer fell into the clutches of the law and it cost $17.50 to secure his release. Then it was found that the traffic regulations of the city had been changed, apparently for the annoyance of the tourists, and the cars were not allowed to stand at the hotel named as noon control. This resulted in some confusion and when the city began to drop back from the horizon everybody breathed deeply with relief. But that was not all, for the Randolph truck, which is carrying the heavy baggage of the tour, was caught in the speed trap late in the day and was stringently dealt with.

The route of the third day of the tour was from New London to Narragansett Pier to Providence and from thence to Boston, about 117 miles. The first stage of the run was over what was once an Indian trail, which legend says was constructed by the great chief Uncas, who lived during the earliest days of the white settlement. Roger Williams, the father of Rhode Island, improved the trail to a certain extent and for many years it was used as the chief means of communication between the villages

Stearns 24-Hour King

AFTER the most marked exhibition of consistent running ever seen in this country, the Stearns car, No. 5, swept under the wire a winner in the 24-hour race at Brighton Beach last Saturday night, scoring 1,253 miles and beating the best previous American figures for the time by 57 miles. In only two hours during the long grind did the Stearns fail to cover more than 50 miles—the sixth, when 48 were scored, and the twenty-second, when 47 were checked off.

Matheson, No. 8, 1,178 miles, finished second. Houpt-Rockwell, No. 4, 964 miles, and Cole, No. 6, 905 miles, were also running when the race was finished. The Matheson came within 18 miles of equaling the previous record.

Nine cars were entered in the race, but only seven of them started, No. 1, Fiat, and No. 9, S. P. O., having been withdrawn before the start for various reasons. The cars that started were: No. 2, Allen-Kingston; No. 3, Marion; No. 4, Houpt-Rockwell; No. 5, Stearns; No. 6, Cole; No. 7, Midland and No. 8, Matheson. All the cars except the Houpt-Rockwell started promptly at the shot of the pistol, missing cylinders delaying that car for a few moments. After the first turn in front of the clubhouse the Stearns quickly went to the front, increasing its lead over the Matheson and Allen-Kingston to two miles during the first hour. The Stearns made 57 miles during this time, breaking the former record of 56 miles made last year by the Buick and the Fiat.

Shortly afterward the two leading cars were laid up for tire trouble, and for about three minutes were compelled to go to their respective camps. There damages were quickly repaired. The Matheson contingent, proving speedier at this work than the Stearns crew, cut the latter's lead down to one mile. About the same time the Houpt-Rockwell developed ignition trouble and on one occasion the flames burst out at the left side of the car, which soon after retired for repairs. However, it was back on the track shortly after.

As the Stearns passed the 89-mile mark it met with a tire mishap, which let the Matheson into the lead, which, however,

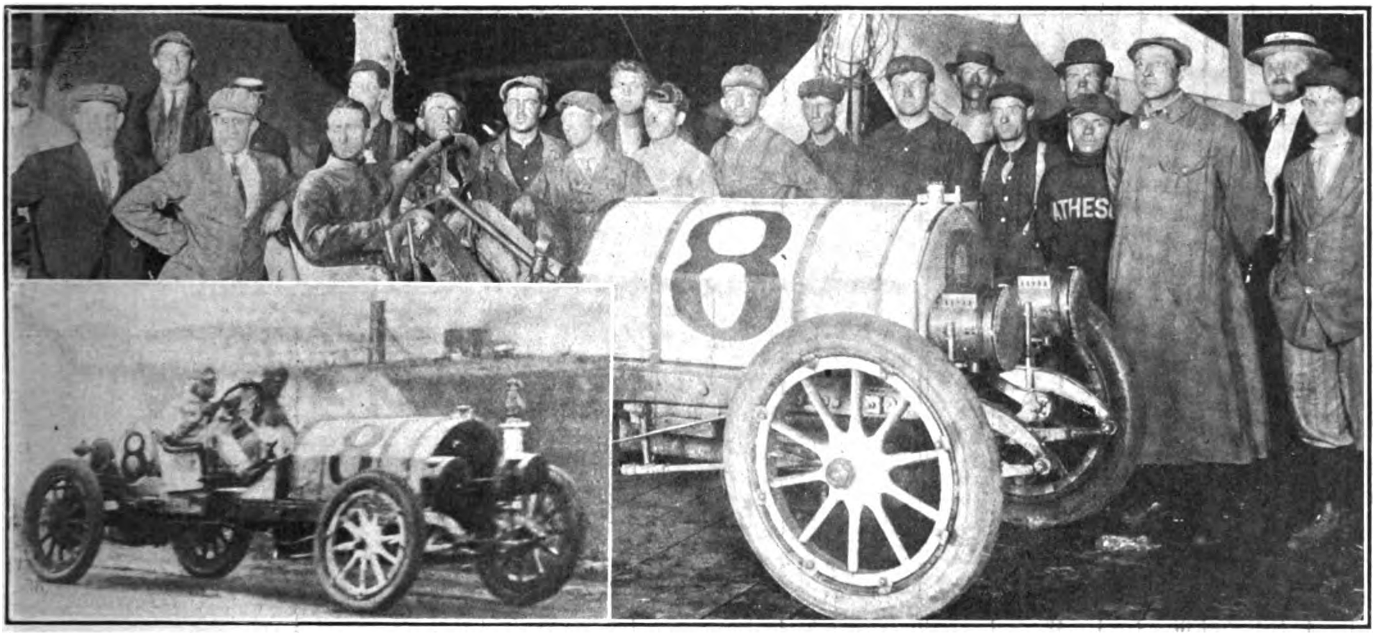
BEATS THE BEST PREVIOUS "TWICE-AROUND-THE-CLOCK" TRACK FIGURES AT BRIGHTON BEACH BY 57 MILES. MATHESON FINISHES SECOND

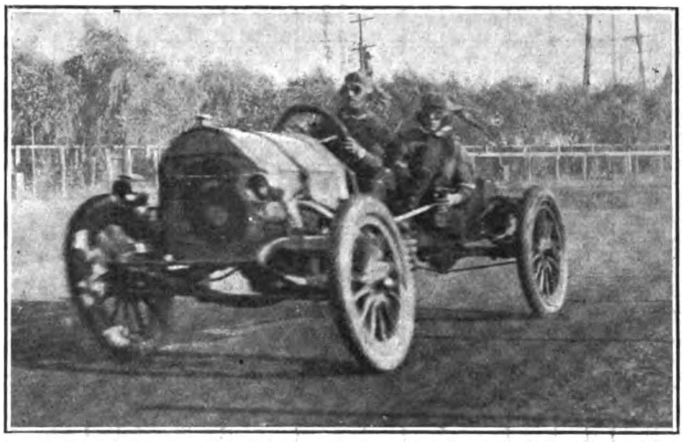
it did not hold for a long time, for after starting on its 104th round its right rear tire exploded and the car skidded into the fence. Owing to its terrific pace it did not come to a standstill before it had gone through the fence for a second time, thereby damaging its left front wheel and steering cross rod. Neither of the two men in the car was injured, but the machine had to stay in the camp for half an hour, which changed the position of the car from first to sixth.

After this the Stearns again went to the front and at the end of the fifth hour it had made 262 miles, being followed by the Cole (243 miles), while both Matheson and Houpt-Rockwell had run 236 miles. During the next hour the latter overtook its rival and at the end of the hour led it by 10 miles. It was during this hour that the first serious mishap occurred, which caused the withdrawal of a car. The Allen-Kingston, with Cobe at the wheel, went through the fence, bending its front axle and breaking its steering wheel and gasoline tank. The driver's face and side were badly cut. An hour before, the Midland had its timing gear damaged and as it also developed valve trouble it had to be taken to the camp for some three hours.



The Matheson outfit, which made a plucky fight—Trying to close up the gap

About 3 a. m. the Houpt-Rockwell broke its universal joint, which took three hours to repair. This car, by the way, changed tires very frequently, and by the end of the eighteenth hour had used 40 of them. Hardly an hour after No. 4 had re-entered the race another car, Marion No. 3, went through the fence and damaged its wheels to such an extent that it had to retire permanently. Wally Owen, who was at the wheel, suffered severe cuts to his face and eye.



Cole, No. 6, was still going at the close of the race

After this the remaining cars continued, the machines going into camp periodically only to take on gasoline or to adjust or change tires. Regarding the latter point the Midland performed especially well, and during more than three-fourths of the time experienced absolutely no tire trouble. In the twentieth hour, however, it met its fate. Owing to the engine being overheated, the car was retired. At the end of the twenty-second hour Houpt-Rockwell went through the fence, breaking a knuckle in the steering gear. Nobody was hurt, but the car was laid up for almost an hour. The other four cars finished the race in this order: Stearns, Matheson, Houpt-Rockwell, Cole.

Al Poole drove the Stearns at the finish of the race, while Charles Basle was at the wheel of the Matheson. The first prize, amounting to $1,500, went to Stearns; the second, $600, to Matheson, while each of the two other cars which finished were rewarded with a prize of $200. The winning Stearns is privately owned by J. M. Rutherford, of New York City, and had been run 40,000 miles before starting in the race. The Stearns engine develops 60 horsepower, that of the Matheson 50, and those of the Houpt-Rockwell and Cole 40 and 30 respectively.

Wants Roads to Serve New York Towns

SYRACUSE, N. Y., Aug. 15.—D. M. Power, of the Maxwell-Briscoe Syracuse Company, calls the attention of the State Engineering Department to a matter of novel interest in the present laying out of State roads. He says of late years the geographical surveys provide only for the obviation of engineering difficulties, the maintaining of a regular grade, etc., to the exclusion of the convenience of communities.

Many such State roads are being built to skip cities of considerable size by as much as three miles. State roads built really to serve the communities, says Mr. Power, would benefit equally tradespeople and tourists.

Industrial Aeroplanes

BY MARIUS C. KRARUP. CONTINUED FROM LAST WEEK. DETAILS RELATING TO EQUILIBRIUM, WEIGHT, SKIDS AND A NEW PRINCIPLE IN PROPELLER CONSTRUCTION

IN the article appearing last week under this title there was illustrated and described in part a type of aeroplane construction in which the requirements for safe equilibrium are met by a number of provisions all designed to work together for the same purpose and therefore forming a suitable basis for a close study of these requirements. To refresh the memory of readers, front and side view diagrams are shown herewith in Figs. 6 A and B representing the monoplane variety of the construction, and the wings are shown in a somewhat extreme adjustment, such as might be required exceptionally in very bad weather in a moment of danger. The wing *L* is turned to a high tilt with its axle in its normal horizontal position, while the wing *K* is tipped around its pivotal suspension at P_1 and at the same time has been turned around its axle, so that the front edge is much lower than its flexible rear edge. The propeller and the skids are not shown. The axles of the wings are designed as consisting each of three spars or tubes spaced triangularly apart with the hypothenuse of the triangle forming part of the wing, while the catheti and the third spar form the necessary reinforcement and extend below the wing. But in the sketches, Figs. 6 A and B, these axles are shown as single spars, X_1 and X_2. The control elements by means of which the wings may be made to assume their whole range of positions jointly or separately are shown with more detail in Figs. 7 A and B, and in Fig. 8, while Fig. 7 C represents details of the skid construction whose practical value, by the way, depends largely upon two other factors in the design, as explained later.

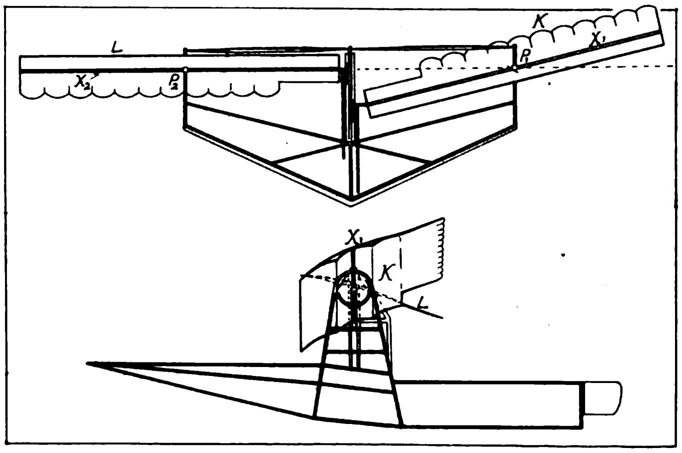


Fig. 6—Front and side view diagrams of monoplane, showing extreme adjustment of planes

The reasons why the design complies with the requirements for enabling an aviator to preserve the equilibrium of the machine under all contingencies may first be recapitulated, though they have been stated at some length in a number of previous articles. And at the same time it may be pointed out, in so far as possible, how and why the construction may be materialized without exceeding the weight limit, and why a construction of this nature seems adapted for industrial development through those methods of manufacture to which the automobile owes its rapid evolution.

As is now becoming more generally recognized, control by rudders depends for safety upon the speed and direction of the machine and is rendered ineffectual when the motor stops and the wind at the same time prevents the machine from assuming the poise for gliding. If the propulsion (not to be confounded with the motor) is weak, the wind alone may interfere with the rudder action. By employing immobile keel planes, either horizontal or vertical, flight in fair weather is steadied, but new dangers are added in irregular weather, when the wind may act more strongly upon the immobile planes than the latter can act upon the air by virtue of the speed of the machine. The whole recent French development, involving increased areas for the immobile surfaces or "empennage" and increased motor power, may therefore be considered as a gambling game in which safety is staked upon the reliability of the motor in conjunction with such fair weather as may be chosen for exhibitions and the winning of prizes. Most of the machines become unsafe when the motor stops working; all of them when both conditions for safety fail. The aeroplane, to become an industrial product, must be on a safer basis. In addition to these reasons for abandoning rudders and "stability planes" and adopting instead a suitable adjustability of the main planes (which in the absence of a positive fulcrum for any control effort means the mutual adjustability of the main planes to the body of the machine and of the body of the machine to the main planes), there may be mentioned the weight and incumbrance of the scaffoldings required for maintaining the rudders and keel planes in their positions far in front or to the rear of the main portions of the machine, as well as the considerable air resistance caused by these scaffoldings.

Some of the difficulties in aeroplane design, and especially those commonly overlooked, may be traced to the fact that the requirements for preserving equilibrium are more severe in the human-made flying machine than in the bird, since the bird can rely absolutely upon its motor power and is of such small dimensions that the chances of a gust of wind attacking one side of its structure, and not the other, are exceedingly remote. But with these more severe requirements the human designer nevertheless has to reckon. The birds, moreover, do not rely on rudders or keel planes, using their tail for a tilt rudder only for hovering and alighting. Their main reliance is in their adjustable wings which are their main planes and propellers, combined.

The construction submitted for study in these articles has not been designed, however, from the bird's or any other living creature's structure as a basis, but from experiments and theories whose adaptation to existing machines dictated one modification after another. The resemblance to a bird which the construction shows in its monoplane variety is purely incidental.

It will be noticed that side steering may be effected independently of the oblique rear rudders. It may be accomplished by tipping the inner wing upward, diminishing its carrying capacity, and at the same time turning it to a higher tilt and increasing the resistance to propulsion on that side. During slow flights with high tilt it may also be accomplished by simply giving the inner wing a quick turn to a tilt above 15 degrees, where the resistance to propulsion increases more rapidly than the lift. For small turns, rises and drops in fair weather one or both of the oblique rudders alone may be turned, the planes always being in reserve to help out the rudder action if necessary.

The advantages of adjustable main planes appear to many so self-evident, in comparison with rudders, that a number of patent applications for this type of design are said to have been filed recently by well-known inventors and engineers, and the tardiness of aeroplane builders in adopting this feature may be ascribed to the difficulties in combining it with sufficient strength and lightness. These difficulties are very real, in comparison

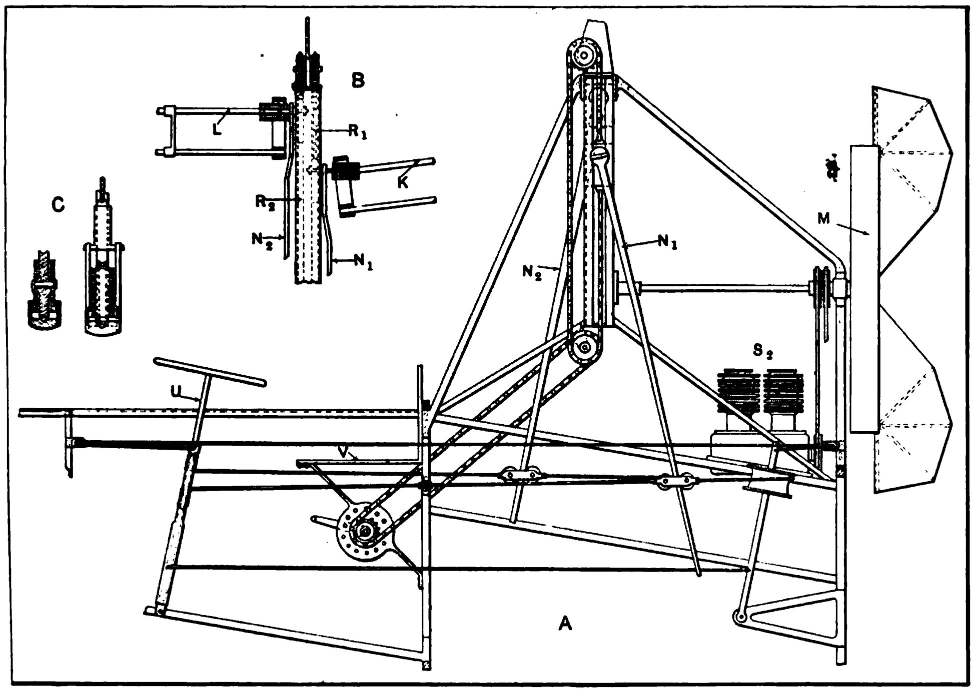

Fig. 7—A, Control elements and propeller; B, Detail view of central slide mechanism; C, Section of double skids and front view of catch for locking and releasing them

with the fascinating ease with which an ordinary biplane may be built from flimsy spars and piano wire stays, but on the other hand all the material which is saved by dispensing with rudder and tail supports may be applied to provide firm support for the points around which the main planes are made adjustable. The stays supporting the pivotal rings, P_1 and P_2, Fig. 6, illustrate the comparison, and the prow and tail in this construction may be of exceedingly light weight, since they taper forwardly and rearwardly and, being covered, are more than self-supporting. Their form, as referred to last week, instead of causing danger by catching the wind obviates the loss of equilibrium by certain self-righting properties. These factors all contribute to sustentation, equilibrium and lightness. In addition, the construction of the planes, with curvatures placed "in series," as also explained last week, is calculated to serve strength, lightness and equilibrium by increasing the carrying capacity per square foot for any given tilt and thereby rendering it possible to reduce the dimensions and wind-catching surfaces throughout the machine for any given weight it has to carry. By choosing the pivots of the wings near their middle, the stresses are minimized and balanced, and the efforts required for control movements are reduced, particularly as compared with any construction by which it might be attempted to imitate bird construction and having the pivots of the wings near the center of the whole machine and at the inner end of each wing, as the bird has it at its shoulder joint.

Not only the apparent difficulties in securing lightness and strength to meet the more concentrated stresses to which a machine with adjustable wings is exposed have militated against the early adoption of this design feature, but also a reasonable advance consideration of the increased air resistance which might be expected in a machine made heavy enough in its parts for supporting this equipment. If the trussed body in the construction shown were uncovered the air resistance against it would be so considerable as to make the design impracticable, but the specific design of prow and tail which goes with it is calculated to not only remove the objection related to air resistance, but to transform this resistance into additional carrying capacity and a means for several other purposes of value. By forming the prow and tail in conjunction with the body proper, as they are shown, the normal resistance to forward movement is figured to be about equal to the resistance against the main planes at all flying tilts and this permits the propeller to be placed midway between the main planes and the body and to have the center of gravity lower with relation to possible disturbances of the balance, or rather the forces brought to bear in such disturbances, than in either biplanes or monoplanes of existing types. That this result is produced may not be apparent at once in comparison with a biplane. The lower plane of a biplane, however, is highly susceptible to disturbing influences, while the under surfaces of prow, body and tail are self-righting against lateral disturbances, which evidently means that the low center of gravity gets an additional chance to correct any disturbance of the main planes; that is, the center of gravity is lower with relation to the disturbing forces. It is further noticed that the shapes of prow, body and tail are self-righting against a backward tumble, so long as propulsion takes place, because any backward tipping brings the under surface of the tail into action as a sustaining surface, while the prow, being placed normally at a tilt which gives nearly maximum sustentation, under these circumstances gives little more sustentation than before. As against a forward dip, the shapes of prow, body and tail are not self-righting, either during propulsion or when the motor is stalled, and with regard to weight distribution the machine is therefore supposed to be so balanced that the forward end will dip, and it remains for the aviator to regulate this tendency by the proper adjustment of the main planes, whether the machine is propelled or gliding. But the natural tendency to dip forwardly corrects that most dangerous possibility of a backward tumble, when the motor is stalled and the all-saving speed for some reason has been reduced, against which no mere shape can prevail, it being amply proven that pure vertical parachute action presupposes much larger areas for the weight carried than can come into consideration for an aeroplane machine.

It is now believed to have been shown that the construction

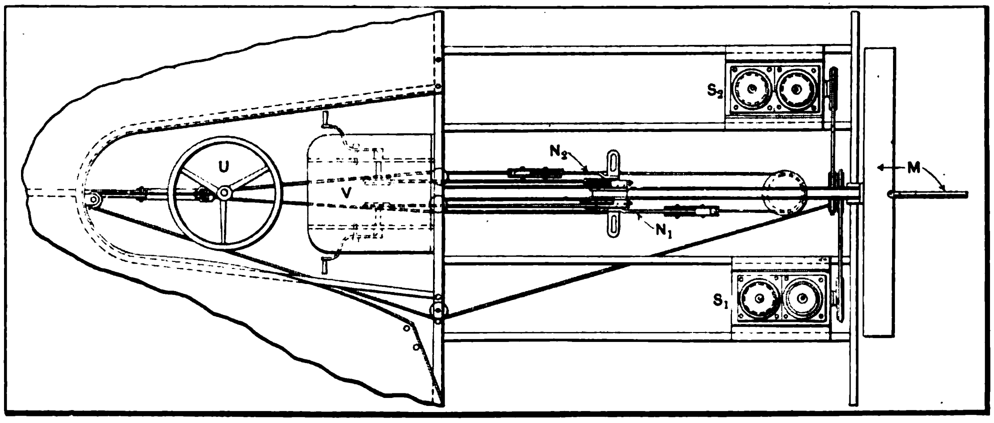

Fig. 8—Top view of control elements for aeroplane with adjustable main wings

illustrates many of the requirements in aeroplanes in general by bringing strongly to mind all the factors and forces involved in the operation of a flight machine and suggesting many ways in which the relations between these forces may be changed by variations in construction. It remains largely a question of engineering judgment and of resourcefulness in the use of available materials to determine the means for reducing the construction, or any similar construction, to its lowest weight limits. Materials and their use form too large a subject to be included in this description, and the writer must limit himself to the statement that he estimates the weight, with one man of 200 pounds and all supplies, including 100 pounds of gasoline or kerosene, at about 1,150 pounds for a machine whose main planes span 28 feet. But by such steel construction as may become practicable by the co-operation of the alloy steel mills or, at much greater cost, by elaborate hand and machine work in such material, it should be possible to reduce the weight to 800 pounds or less with some incidental gains in the reduction of air resistance.

Two extraordinary advantages in a construction deriving its control from adjustable main planes relate to speed variations and to the possibilities for producing very large airships of great carrying capacity. The suitability of the construction for the highest as well as the lowest speeds follows simply from the adjustable relations between the load and the planes, which permit the machine to find its balance in the atmosphere at the tilt which gives the highest resistance against propulsion as well as at the tilt which gives the smallest resistance and therefore the highest speed, without any necessity existing for correcting the balance by a retarding rudder action. The possibility of building large structures follows from the easy adaptation of the design to tandem arrangement. The irregularities in sustentation which have interfered with all previous arrangements of tandem planes naturally fall away when the regulation of the course is accomplished by the mobility of the planes themselves rather than by the operation of rudders, at the front or rear, whose task is so much harder as the extension of the planes fore and aft, collectively, is greater. The possibilities in this respect seem sufficiently attractive to enlist the interests even of those who believe in the development of control by rudder for aeroplane machines of small capacity.

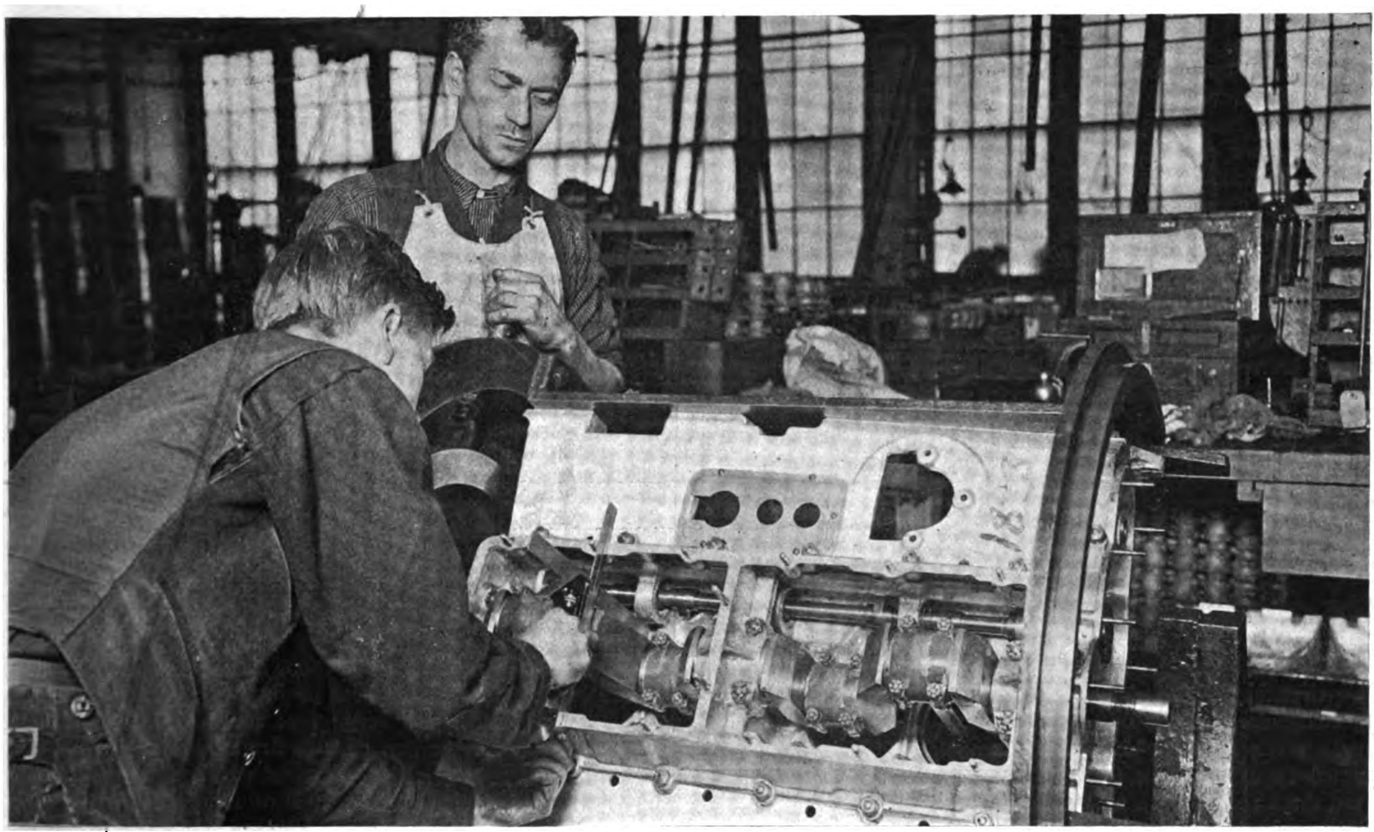
In Figs. 7 A and B and in Fig. 8 certain definite mechanical expedients for effecting the desired control of the main planes are illustrated with sufficient detail to be self-explanatory, in connection with the brief description given last week. As presented they merely show that the control is within the range of practical mechanics.

Mention of the propeller design and of the skids has been reserved for the last because these features represent ideas whose organic connection with an aeroplane construction designed with a view to industrial development and the safeguarding of equilibrium is less close than that of the features already described, and because the practicability of skids designed to launch an aeroplane in the air with a run not exceeding 6 to 8 feet depends greatly upon obtaining a much stronger propulsion from the propeller than has ever so far been obtained in aviation practice and also somewhat upon the efficacy of the special construction of planes, with curvature "in series," which was described in the first instalment of this article. Without the reduced air resistance for a given lift which these planes should produce and the increased propulsion for a given motor power which the propeller construction should produce, the chances for imparting a starting speed of twenty miles per hour, or more, to an aeroplane machine weighing more than half a ton, by a run of only a few feet, seem anything but encouraging, but it is nevertheless means for accomplishing this result under favorable circumstances which are indicated in the skid construction shown in Fig. 2, last week, and in Fig. 7 C. It is assumed that by providing the upper runner of the double skid with anti-friction rollers and the lower one with a wire rail, for the rollers to run upon, and a releasable catch by which the machine and the upper skid-member may be held back until the propeller operates at its full power, the retarding as well as the jolting effect of more or less uneven ground may be so far reduced that a machine with a maximum of propulsion and sustentation and a minimum of resistance may gain the necessary speed on the short run. As shown in the sectional view, Fig. 7 C, the machine is of course intended to carry the whole skid device in flight by means of the flanges on the lower member.

The propeller is combined with a flywheel of thin, rigid material serving the purpose, aside from the flywheel functions, of maintaining the front edges of the two propeller blades rigid while the rest of the blades are turned from their rest positions, which may be in a plane laid through the shaft, to a pitch determined by the speed of rotation and their resilient resistance against deflection. The blades, in other words, are turned to pitch by the air resistance which they encounter. Their efficiency as propellers is poor for any speed of rotation which falls much below that which produces suitable pitch but rises rapidly as this pitch is approached. The pitch is modified by external circumstances, such as sudden gusts of wind or eddies or high forward speed, the blades responding automatically to all forces increasing or lessening the pressures. Probably the most suitable pitch may be found higher for resilient than for rigid blades. The propeller blades are indicated in Fig. 7 A and in Fig. 8 as being perfectly flat, but in reality they should be formed with a pressure surface slightly hollow transversely, and in addition with shallow air pockets corresponding in nature and purpose with the sub-curvatures employed for the under surfaces of the main planes of the machine. The resilient resistance against the deflection of the blades is provided partly by making the material of the blades, except the entire front edge, resilient, as by securing skin or rawhide to flexible steel fingers, but mostly by attaching an adjustable, multiple helical spring to the flywheel rim, near each blade, and compelling the blades to stretch the springs when turning to pitch. By cutting out a niche in the inner wooden felloe of the flywheel rim, the springs may be placed so as to cause neither air resistance or sound in objectionable degree. To serve as a base for the spring action is the third function of the flywheel and a useful one in practice, as it would require endless experimentation to build resiliency directly into a propeller blade and have it commensurate with a given motor power minimum, with the degree of accuracy necessary for accomplishing much better results than may be obtained with a propeller of the customary almost rigid type, when the latter is provided with improved curved pressure surfaces. In theory, however, the relations between the rigid and the resilient propeller are fairly clear. Assuming that two propellers are alike in all features, excepting that one is rigid and the other capable of turning around its rigid front edge, as described, against an adjustable resistance, it is readily seen that the motor must do more work to turn the resilient propeller at a given speed than for turning the rigid one. If the speed is insufficient to create a resistance which will turn the resilient propeller's blades to the same pitch as that of the rigid blades, the requirement for greater power follows from the higher pitch alone, since it is contradictory to assume that high pitch, with equality in all other things, can be driven as fast as low pitch with the same power. Further, as the resistance to rotation must at all times be at least equal to the resilient resistance against the deflection of the blades (plus friction), since it is this resistance to rotation which alone causes the deflection, it becomes mathematically certain, by comparing these two impregnable inferences, that the motor power in the case of the resilient propeller must do both the rotating and the deflecting, while in the case of the rigid propeller it does the rotating only. If then the resistance against deflection of the resilient blades is arranged to be equal to their resistance against rotation at the pitch of the rigid propeller, it will require twice as much motor power to rotate the resilient propeller at the speed which will produce this pitch as for rotating the rigid propeller at the same speed.

(*Continued on page 338.*)

Proper Assembling Represents Half the Quality



ERECTING MOTORS AT THE PACKARD PLANT, ILLUSTRATING THE USE OF SPECIALLY CONTRIVED STANDS

ADVERTISING a fallacy does not make it a truth, but it does induce a large number of people to believe that the statement is founded on fact. It has been advertised year after year, and in a thousand ways, that carbon formations in the combustion chambers of a motor's cylinders come from using too much poor lubricating oil. The distillers of lubricating oil may or may not have believed the story; at all events, all they have ever done about it was to recommend the use of the finest grades of lubricating oil, which is the proper course in any event, but in the meantime carbon trouble in motors has gone on uninterruptedly quite independent of the lubricating oil employed, for the very good reason that the major portion of the carbon which is at the bottom of all complaint comes from the use of an excess of gasoline or the right amount of gasoline in the absence of a sufficient volume of air to supply the requisite quantity of oxygen with which to set fire to the fuel and burn it to finality.

In many of the plants at the present time experiments are going on with a view to determining the real cause for carbon formations, and from what has been learned already it is a moral certainty that the growth of carbon as it is caused by lubricating oil is infinitesimal as compared with the carbon accumulations from other sources, as poor carburetion, improperly provided compression and ignition systems of no great competence.

It would seem that carbon is likely to form in motor cylinders if the compression is very high. When the compression ranges around 75 pounds per square inch absolute, the accumulation of carbon that may be traced to compression is negligible.

If a good ignition system is employed and it is maintained in proper working order, combustion is far more complete and the carbon trouble is much deferred. The reason why ignition may be at the bottom of trouble of this sort is explained as follows: If the ignition does not take place at the proper time the chances are that a portion of the fuel will be burned to incomplete combustion, the terminal pressure will fall below the desired point and conditions of inferior scavenging will set in.

The greater part of carbon trouble, however, must be charged to inferior carburetion, and that this source of trouble is becoming more acute every day is recognized, due to the fact that the non-volatile constituent in the gasoline supply is being increased from time to time at the cost of the more volatile hexane which is being decreased in the same ratio.

If it will be remembered that fully 50 per cent. of all the volatile portion of crude oil belongs in the distillates approaching decane, it will readily be appreciated that the distillers of oil are extremely anxious to have decane liberally represented in automobile gasoline. It is not believed that they consult the builders of carbureters in matters of this sort, nor is there any record of their having called a convention of autoists with a view to being favored with its opinion as to the efficacy of kerosene oil for use in automobiles.

Surprising as it may seem, the inventors of kerosene motors have been put out of business due to the improvements wrought in carbureters and the splendid backing of the distillers of crude oil. Just as fast as carbureters are improved so that they are rendered more capable, the distillers of crude oil add another dash of the less volatile constituents until finally the carburetion problem has arrived at a near approach to the time when automobile gasoline may contain 50 per cent. of kerosene oil.

Since this is the exact amount of kerosene oil present in the whole content, there is no inclination on the part of the distillers of oil to add more—it would even be a detriment to do so.

The thermal value of automobile gasoline as it now obtains is slightly better than that of true gasoline. This is a fortunate circumstance, and it means that more power will be delivered from a motor that is capable of burning automobile gasoline than can be taken from a motor that is fed on true gasoline, the difference being sufficient to be well worth taking into account.

But it is to the detriment of good operation to try to burn the automobile gasoline of to-day, using a carbureter that may have worked extremely well in the days of hexane.

Unless carbureters are so designed that they will vaporize automobile gasoline, it will, of course, pass into the combustion chamber in liquid form, where it will "crack," precipitating carbon, forming a hard crust, which interferes with the proper thermal action of the motor. Cylinder oil plays a small part in this malperformance, since it serves as a binder for the precipitated carbon, to which must be added silicon and other silt formations, which are sucked in through the orifice of the carbureter, and carried into the combustion chamber.

Some of the experiments that were conducted seemed to show quite conclusively that silicon alone does not form a crust in the combustion chamber, so that if the gasoline can be prevented from cracking, there is almost no danger of carbon trouble or the formation of a sufficient crust to produce noticeable trouble.

This is but one of the several important fields that are receiving the attention of the capable engineers whose life work lies in the building up of the automobile. Unfortunately, there is so much to be done, and there are so many questionable traditions to be lived down, that progress, however substantial it may be, takes on pigmy proportions as measured by the wants of the industry. Just how long it will be before this many-angled situation is reduced to a satisfactory working level is hard to predict, but it does seem as if the advertising of fallacies should be confined to "paid for" space, if it is to be tolerated at all, although it is difficult to understand why such an undertaking would be worth paying for. In any case, it is believed that the greatest offenders are among the class of information dispensers who cater to the editorial pages of the technical press, many of them dealing in synthetic matter rather than relating proven facts.

Automatic Tire Pumps

SHOWING A TYPE OF AUTOMATIC TIRE PUMP WHICH IS WORKED BY SUCTION AND COMPRESSION FROM THE MOTOR CYLINDER WITH AN AIR PUMP IN TANDEM RELATION

ACCORDING to the best advices obtainable from makers of tires, supplemented by the practices among taxicab operating companies, the life of pneumatic tires is shortened more if they are run when deflated than from any other cause. It is claimed by experts that a tire is too small for its work unless it will maintain a substantially round shape at the point of ground contact when it is supporting the total load. With a view to obtaining the greatest possible tire life, the first requisite under the circumstances is to employ tires that are sufficiently large to sustain under the load without inducing flexure.

It is a well-understood fact in connection with steel and other materials that they will deteriorate rapidly if they are subjected to flexure, and the only material obtainable that seems to last for a commercial length of time under conditions of flexure is spring steel. Even this product gives out much too soon, and every autoist of experience realizes that the chances of breaking the springs upon which the body rides are very great indeed. Moreover, statistics conclusively show that next to tire trouble springs play a second part from the point of view of failure in service.

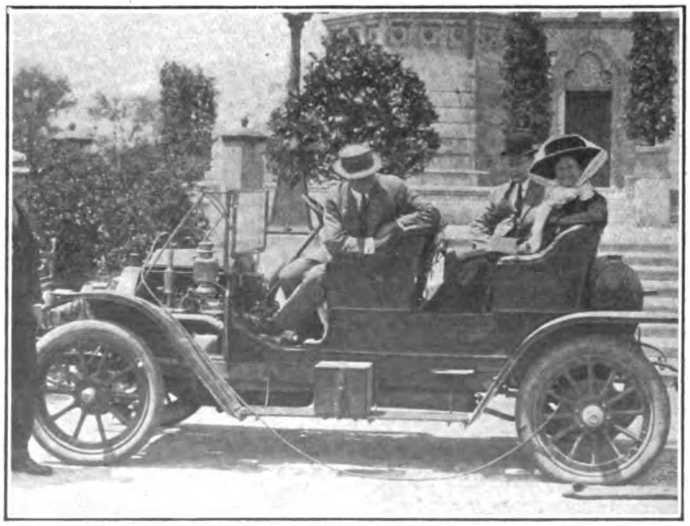


Fig. 1—Depicting the pump in place on a car and the pressure tubing leading back to the left rear tire, which is being inflated

Flexure and shock are at the bottom of spring breakages, but it must be remembered that tires take the initial shock, and it is much subdued by the time it is taken up and dampened by the action of the springs. If the finest grade of spring steel is barely capable of sustaining under conditions of secondary shock together with flexure, it is scarcely to be expected that tires will satisfactorily support initial shock and stand the hardship of flexure besides.

It is impossible to get around the initial shock condition. Tires are used on wheels for the purpose of taking it, but

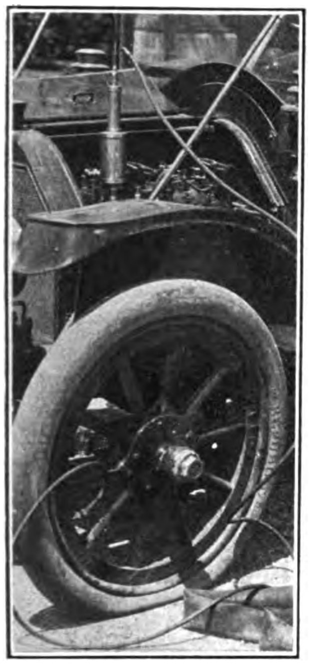

Fig. 2—The pump in place on the motor and the pressure tube leading to the left front tire

it is possible to avoid subjecting them to flexure as well, provided of course the tires are of sufficiently large section in the first place, and if they are sufficiently inflated besides.

The average autoist seems to think that tires will not stand a high pressure. On the other hand, one expert whose ability is recognized in the tire world has carried the inflation problem so far that he used a pressure of 500 pounds per square inch in bicycle tires without endangering the fabric on account of the high internal pressure. If a bicycle tire will withstand this high pressure, there can be no possible chance of inflating automobile tires by any ordinary means to a pressure sufficiently high to endanger the fabric through high fiber strain from this cause.

The one thing that an autoist can do that will reduce the cost of tire maintenance to the lowest possible limit is to maintain the condition of inflation so that the tire where it contacts with the ground will remain very nearly in the same state of roundness as it will be at any other point in its section. That there will be a slight flattening is unavoidably true, but in no case should this flattening be more than that which will reduce the radial diameter of the tire by 1-5 of an inch.

It is now the practice among some of the makers of automobiles to supply power pumps, gearing them from the motor at some convenient point, and so arranging that the autoist will have no excuse for running on partially inflated tires. There are a vast number of automobiles in service, however, that are not provided with power pumps for this purpose, and the Skinner & Skinner Company, realizing the importance and scope of this field, is marketing a power tire pump that may be attached to any automobile, involving no greater undertaking than the removal of a spark plug and the screwing into place of the power pump. These pumps are manufactured by the company, at 1716 Michigan avenue, Chicago, Ill., and they are so put out that they will fit into place without trouble if the autoist desiring one is careful to state the make and model of his particular car.

Fig. 1 shows the power pump in place on an automobile, and the pressure tube leading therefrom to the valve of the tire on the left rear wheel. The motor is turned over slowly, running on three cylinders while this work is being done, and under ordinary conditions the tires are pumped up to about 90 pounds per square inch. Fig. 2 shows the tire pump reaching out above the bonnet, and affords an excellent idea of its size relative to the dimensions of the motor and relating parts. Fig. 3, however, presents the tire pump with the motor almost cut away, showing the thread of the pump, T1, screwing into the spark plug opening, S1. The large cylinder, C2, holds a reciprocating piston, which is actuated first by the suction of the motor which pulls the piston down and, second, by the compression of the motor, which pushes the piston back again. The small cylinder C1 holds a piston in tandem with the working piston, there being a connecting rod between. When the power piston reciprocates, due to suction and compression of the motor, the small cylinder reciprocates in unison, taking air at the end of the down stroke and compressing it on the up stroke, so that it passes out through the valve V1 into the connecting hose H1, thence to the tire to be inflated. For the purpose of admitting free air to the small cylinder, a hole is provided so that when the air piston is at the end of the down stroke the hole is uncovered and the air is free to rush into the small cylinder.

The working cylinder being relatively large in area is capable of supplying the necessary force to compress the air in the small cylinder to at least 100 pounds per square inch, and the pump is so contrived that nothing but pure air can enter the air pump and find its way into the tire to be inflated. Fig. 4 is a section of the pump showing the relation of the two pistons and the connecting rod between, also the spring buffers at the top and bottom of the stroke, by means of which the reciprocating motion is arrested, and the piston set is accelerated in the reverse direction as many times as the occasion requires, without shock or other deteriorating troubles.

The entire outfit is substantially made, using brass tubing, and high duty brass fittings; the joints are threaded and thereafter brazed so that leakage is avoided and the relations of the parts remain firm without showing depreciation in service. The pistons are leather packed, using a special grade of material which has long served in this class of work in other fields, and which proves to be the most efficacious in this work. The pump occupies even less space than a reasonably capable hand-pump, it being somewhat shorter and very little greater in diameter. When it is through with the work of inflating a tire, it is screwed off of the motor, and may be packed away in the tool box, where it will remain without danger of being damaged, ready to take up its burden again should the occasion require.

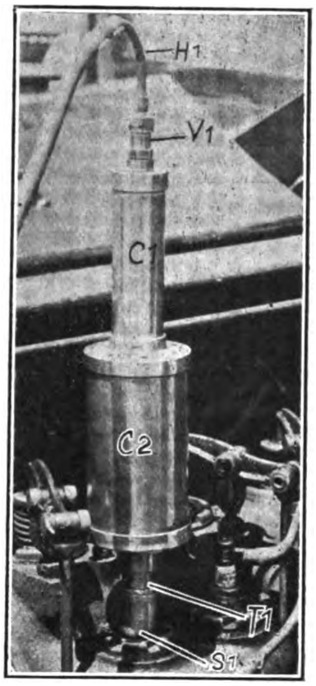

Fig. 3—The pump screwed up in place of a spark plug on the cylinder of the motor

In applying the pump it is not necessary to use a wrench of any kind. Hand pressure in threading on the pump will bring it home with sufficient force to make it tight, and when it is to be removed the same reasoning applies. In operation, if the tires are of large section, and diameter, all that is necessary to obtain a sufficiently high pressure is to speed the motor up a little, and with this facility the autoist soon learns just how fast it is necessary to speed the motor to gain the right pressure. In service the pump runs quite silently, due to the entire absence of any mechanism that can develop lost motion, and there being no gears employed, noise cannot be expected. Connecting hose may be of any desired length and while ordinary rubber tubing is used in most cases, metallic hose is also available.

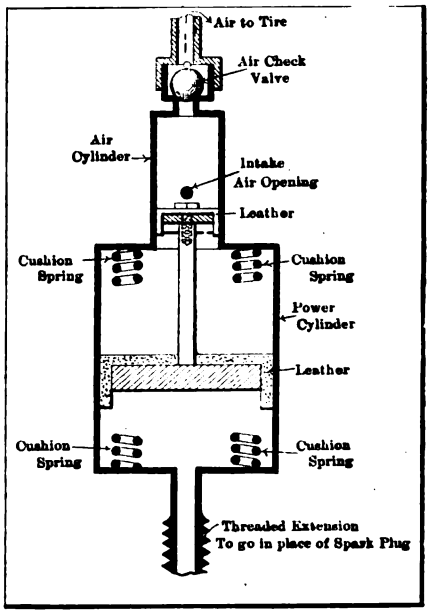

Fig. 4—Cross-section of the pump, showing the connection between the power and air pistons and the buffer springs

The Vortex Vaporizer

PRESENTING A NEW IDEA IN CARBURETER DESIGNING; FUEL IS HEATED TO OVERCOME THE LATENT HEAT OF EVAPORATION; LARGE GLOBULES ARE CAST OUT

JUST what is the composition of "automobile gasoline"? Until this question is answered to the satisfaction of the reader it will be difficult to go on with any explanation of the vaporizer under discussion. The whole range of the hydrocarbon distillates is scheduled as follows:

	Boiling Point Deg. F.
Rhigolene	113 to 140
Chymogene	
Gasoline	140 to 158
Benzine C	158 to 248
Benzine B	248 to 347
Benzine A	
Kerosene	338 to 482

In the early days of the industry, when gasoline was a by-product, it was limited to that as above stated, in which the distilling temperatures were between 140 and 158 degrees Fahrenheit. This distillate existed in crude oil to the extent of 1.5 per cent. It was soon found that there would be a shortage in the supply unless some other fuel could be found that could be used to advantage in automobile motor work, and naturally the distillers of crude oil expressed a preference for the use of heavier distillates of crude oil rather than to have the trade diverted to alcohol. All that seemed to stand in the way of the use of the heavier distillates was the rather poor working of carbureters, and one way to bring about a reform of this part of the automobile was to slowly but surely widen the range of the distillates in the mixture and gradually influence for the better performance of carbureters.

That this policy on the part of the distillers of crude oil was carried out is plain to be seen; each year brought about a change in the fuel to be had upon the market, and the time finally arrived when it was found that the character of the fuel was so heavy and non-volatile that it would not give a reasonable measure of satisfaction when used in the ordinary way.

That this policy on the part of the distillers of crude oil is to be looked upon as an imposition is not believed; the price of every commodity advances as the demand increases, and in the case of (real) gasoline, had it been maintained, the demand would have been so great that the price would have been prohibitive even before the automobile industry reached one-quarter of its present proportions.

But the time has come when it will be necessary to consider further encroachments on the residuum of crude oil in favor of fuel for use in automobile motors. Of all the available distillates between rhigolene and kerosene 50 per cent. belongs to the latter. If this supply could be utilized the whole situation would be enormously relieved, and that some kerosene is now finding its way into automobile gasoline is believed.

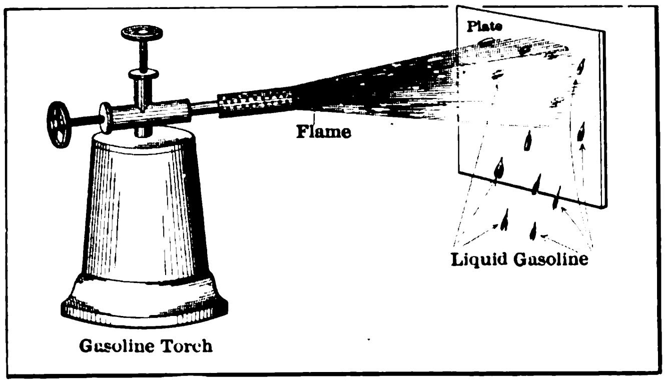

Fig. 1—Experiment using blow-torch indicating non-burning qualities of heavy distillates in the presence of highly volatile hydrocarbons

To whatever extent kerosene is added to the fuel that is now being furnished to autoists, it is just as much of a waste as so much water, unless the carbureter is so designed that it will heat the liquid gasoline and vaporize it before it is allowed to enter the combustion chamber of the motor.

The claim will naturally be made that there will be plenty of heat in the combustion chamber of the motor to vaporize the kerosene if it is present, and that it will be used as fuel under these conditions. Every autoist who is having trouble due to the formation of carbon in his motor is ready to testify to the fact that there must be something the matter with the explanation that fails to explain, and the time is ripe to point out that it takes more than heat to render kerosene oil combustible, and oxygen forms the remaining link.

True, there may be enough oxygen taken in with the fuel to serve for the purpose, but even then it is more than likely that the oxygen will not have time to mix with the fuel after the latter is vaporized within the cylinder, and, unless it does, the fuel will "crack," forming carbon, which will settle upon the surfaces of the cylinder, there to remain until it is scraped off.

That carbureters have been improved from time to time in keeping with motor requirements and the fuel problem is a settled matter, but it is becoming more apparent every day that the end is not yet, and autoists are complaining of the troubles they are having with growths of carbon, and the considerable quantity of residuum that has to be thrown away. But this is not all; smoke ordinances are rapidly being promulgated, and that poor combustion is one of the most prolific reasons for the smoke nuisance is too true to be ignored.

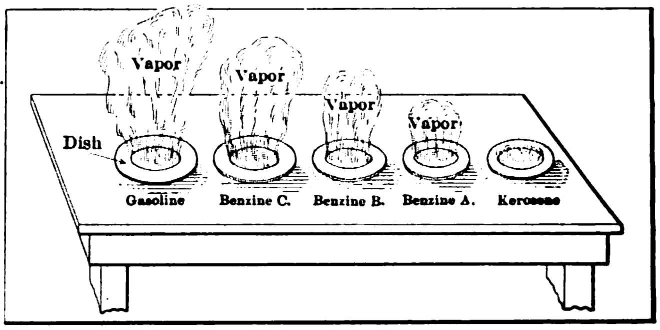

Fig. 2—Dishes holding the several distillates showing the rate of evaporation of each

If there is one thing above another that the autoist of experience dislikes it is the odor of partially burned gasoline; the pungency of the odor is only equaled by the poisonous effect it will have upon the system of the autoist, and these are additional reasons why it is necessary to keep everlastingly at the carbureter problem, not so much with the expectation that a perfect one will ultimately emerge from the brain of some wonderful thinker, but that the pace will be maintained, it being a contest between:

(A) Decreasing volatility of automobile gasoline, due to the growing use of kerosene in the mixture.

(B) Greater demands on account of the improvements that are being made in motors.

(C) More exacting requirements on the part of autoists who appreciate the fine qualities of flexible motors.

Peculiarities of Composite Mixtures of Fuel

When gasoline is made up of certain percentages of gasoline, benzine and kerosene, admitting that each produce has its own degree of volatility, the whole volume of fuel will not burn at the same rate, even if it is all set on fire at the same time. Fig. 1, of a torch of the kind in common use by repairmen, shows how some of the gasoline burns and the major portion of it passes through the flame and splashes up against the plate that is placed quite a distance away, but in line. What does this signify? It is proof of the fact that some of the fuel is so slow burning that even in the presence of an excess of atmospheric air, and plenty of flaming gasoline to ignite it, even so, it will not burn readily.

There is another very simple way to show that there is a great difference in the volatility of the respective contents of gasoline. Purchase a specimen of each of the distillates, as true gasoline, benzine C, B and A, also kerosene, and put a given weight of each in as many saucers placed in a row as indicated in Fig. 2, where a draft of air may strike them, and note the time taken for each content to evaporate. It will be found that the gasoline will evaporate very much faster than the benzine C, and that benzine C will evaporate faster than benzine B, but that benzine A will be slower than B, and that kerosene is very slow indeed.

Sizes of Globules Also Have to Be Considered

That the globule structure of each of the distillates is not the same may be proven by putting gas made from each of the distillates into rubber tires under pressure, when it will be found that the pressure will not fall in each of the tires at the same rate, thus indicating that the several products have different characteristics in this regard.

In liquid form, under pressure, when the several liquids are projected from nozzles, they will not all perform the same; some will split up sooner than others, and this characteristic must also be considered when an attempt is made to gasify the several liquids. Now, what does happen? How is this point to be illustrated to bring it home clearly to the man who has no time to study the situation at length? Perhaps a cannon will suffice for the purpose; when a ball is shot from the mouth of a gun the partially burnt powder, and much smoke, comes out of the mouth of the gun, looking as shown in Fig. 3.

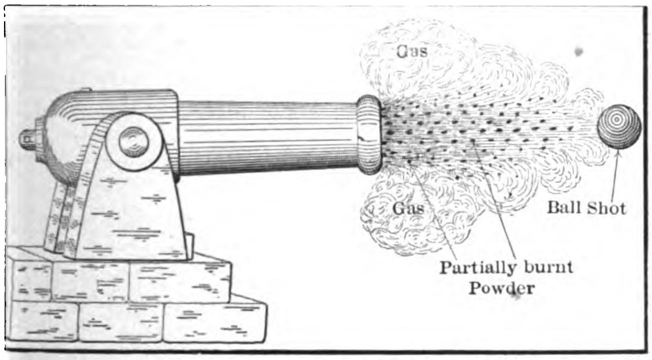

Fig. 3—The firing of a cannon taken to illustrate the action of the various distillates used in automobile gasoline

It is easy enough to understand that the ball travels faster than the partially burnt powder and the smoke. Why, then, will it not be easy to understand that the partially burnt powder will travel faster than the smoke? Of course it does. What is the result? Just what the illustration depicts. How is this phenomenon related to the questions of fuel and carburetion? If it will be remembered that heat must be absorbed by liquid gasoline before it will vaporize, and that it takes substantially 0.500 B.T.U. of heat to accomplish the task, one phase of the problem will be in a fair way to a proper understanding. But if heat is necessary to accomplish the task, the next question is, how shall the transfer be made with certainty and within the time limit, which, in this work, is very short?

Heat will transfer from one body to another if there is a difference in temperature between them, and the amount of heat that will exchange will be directly proportional to the difference in temperature. But there must be surface as well. Of course, each particle of the gasoline as it is ejected from the nozzle has surface, but the area of that surface will not be the same for all unless all are of the same size. Are all of the globules of gasoline of the same size? Unfortunately, no.

Even the differences in the sizes of the globules of the gasoline from the nozzle would not make so marked an effect on the final result were it not for the law of spheres.

The surfaces of spheres as they relate to mass are illustrated in Fig. 4.

What does it signify? With gasoline as it formerly obtained, that is to say, true gasoline, the significance was worthy of note, but it was far below that which must be noted with composite fuel such as automobile gasoline.

The illustration, Fig. 4, involving spheres, shows that the mass increases at a rate higher than the surface. The result is that the larger globules of gasoline will require a much longer time in which to vaporize, assuming a fixed difference in temperature for all.

But if some of the globules are composed of the less volatile products, as kerosene, the trouble is far greater. With kerosene as compared with gasoline, even were the globules of the same size, the gasoline would evaporate with great speed as compared with the kerosene.

The problem, then, in view of the actual presence of a double complication, is one that must be solved on a basis that will check with the demands of the controlling laws.

Just What Must Be Done to be Successful

Granting that the problem is one which has for its foundation the delivery of an efficient mixture into the combustion chambers of the cylinders of the motor, free from liquid fuel, the situation may be re-stated as follows:

(a) Account must be taken of the fact that all the globules of the fuel, as they spout out of the nozzle of the carbureter, will not be of the same diameter, partly due to the action which goes on in the nozzle, and largely on account of the composite nature of the fuel.

(b) When the fuel issues from the nozzle of the carbureter it must be screened, that is to say, all the globules of the same volatility and size must be allowed to mix with the stream of air and be vaporized in quantity sufficient to afford a capable mixture.

(c) The globules of low volatility and larger than those available for instant use must be screened out and held in a trap until they absorb enough heat to vaporize them, after which the vapor must be taken up by the inrushing air, but this process must not upset the normal balance of the mixture.

(d) Means must be at hand for promptly adjusting the quantity of air in proportion to the changing needs.

One of the facilities demanded under the circumstances is a source of heat.

What is the best source of heat? That which will afford a constant temperature and as many heat units as the demands in view of the latent heat of evaporation of the gasoline, to-

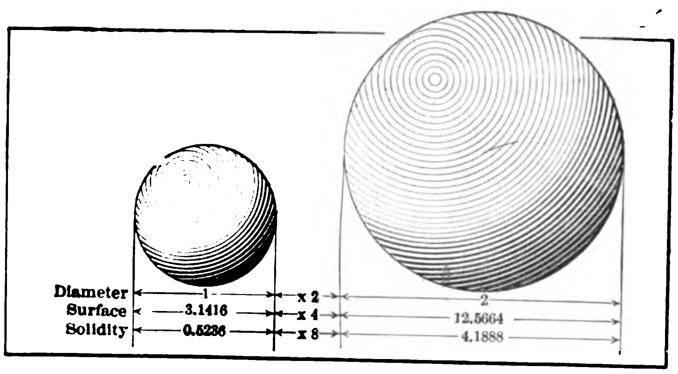

Fig. 4—Placing two sizes of spheres to elucidate the text in relation to the sphere law

gether with the requirements as based upon the specific heat of the air and the vaporized liquid.

Heating the air as it rushes into the carbureter is not in accord with the requirements; there is no way of accomplishing this so that the air will always remain at a constant temperature, and, unfortunately, the temperature of the air so heated is lowest just when it should be highest.

Heating the gasoline before it sprays out of the nozzle offers attractions, but this plan has the misfortune of disturbing the balance, due to the fact that the quantity of gasoline that will issue from the nozzle in a given time depends upon its viscosity and this property changes with the temperature of the liquid. A more stable method of heating depends upon the use of water circulating through a properly contrived jacket around the depression chambers of the carbureter. The water is heated to substantially a constant temperature in the cylinder jackets of the motor, and it is maintained at the working temperature by the radiator. True, even water under such conditions does not hold at a constant temperature level, but it is far more constant than heated air. The temperature of the water is high enough to serve for the purpose, and it is poor economy to heat the fuel higher than just the temperature that will suffice for the needs.

Fig. 5—Section of a snail-like curve offered to illustrate the principle of the vortex

If the large globules are screened out of the train and held in a trap until they vaporize, the working temperature may be held at a far lower level than would be true under other conditions. This idea, then, has more than the ordinary merit.

How is it possible to screen out the large globules of liquid fuel and hold them in "limbo" until they take on enough heat to reduce them to a stage of vaporization? How does the cream separator separate the butter-making contents from the milk, leaving skim milk as a residuum? Shall we call it a vortex action, for short, or shall we quote such of the laws of Newton as justify the contention as it is manifest in the illustration of the cannon ball and the products of combustion of powder? At all events, centrifugal force is imparted to all the particles that are engaged in the vortex swirl, and energy will reside in each of the particles independent of the other on a basis of:

$$E = \frac{W V^2}{2g}$$

When,

E = energy stored in the mass;
W = weight of the mass;
V = velocity in feet per second;
g = force of gravity.

Since the large globules weigh more than the smaller ones, does it not stand to reason that they will reside in a more pronounced state of energy, and, if this is so, is it not a fact that they will part company with the smaller globules, flying out at a tangent for a great distance, unless they are restrained?

What is there to restrain them? Certainly nothing within the body of forming mixture worth taking into account.

When the forming mixture is given the swirling motion as in a vortex, and energy is imparted to the respective globules of fuel in proportion to their respective weights, the larger and heavier globules will work up and out, so that after a few revolutions all the heavy particles will be found on the outer rim of the swirling mass and all the "mist" particles will work in toward the center, or, properly speaking, will be crowded in toward the center or core of the vortex, as shown in Fig. 5.

A Point That Has Never Been Discussed

It will be remembered that the best mixture of gasoline and air is in the proportion of 8,000 parts volume of air to one volume of liquid gasoline; it is also claimed that the richest mixture that will burn has 3,500 volumes of air to one volume of liquid gasoline, and the leanest mixture that will ignite has 10,000 volumes of air to one volume of liquid gasoline. Plotting a curve of these values presents an angle that is even a little startling, as Fig. 6 will show. Of course, the nearly exact proportion of air to gasoline for the best result in practice depends upon the compression; if the compression is very high, more air must be used. The reason for this lies in the fact that the time allowed for the proper mixing of the air and the fuel will be lowered, due to the higher obtainable speed under conditions of higher compression.

The curve, Fig. 6, looking at it from this angle, indicates that rich fuel proportions will work satisfactorily at the lower speeds, and that the torque of a motor should be maximum at the lower speed; also that it will not hold constant at all speeds.

The problem in carburetion is to realize the greatest possible torque at low speed and to fight off the tendency of the torque to fag as the speed is increased.

The way to accomplish this is to sort out the globules of less volatile gasoline and give them time to vaporize; then allow the vapor to enter the train and to be turned to good account in the combustion chamber of the motor. The vortex idea is put forward as a good one for work of this character, and the result in practice of the utilization of this idea is shown in the curve, Fig. 7, of performance of a 4-cylinder, water-cooled, 4-cycle motor of conventional make, with cylinders of 5 1-2 inches bore and 6 inches stroke.

In this curve the ordinates are plotted for speed, and the abscissæ are given values in horsepower. The curve is almost straight between 550 and 1,300 revolutions per minute of the crankshaft of the motor delivering 68.2 h.p.

A closer inspection of the curve discloses a slight kink in the same at 60 horsepower, which was delivered at 1,090 revolutions per minute. At about 1,350 revolutions per minute the curve takes a sharp fall; this is a sign that the motor valve system reached the limit of its capacity; it is not a sign of lack of ability of the carbureter in this case. Were the carbureter at fault there would be other indications, as a wavering of the curve before the knee of the same was approached.

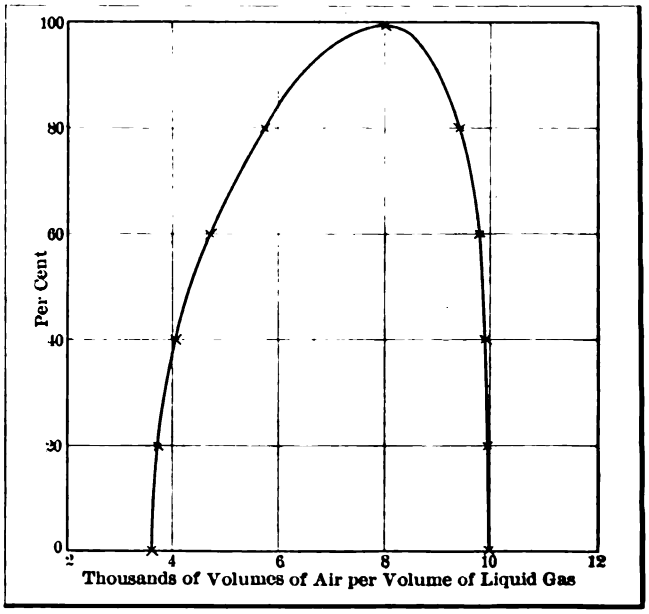

Fig. 6—Curve plotted to show the relations of air to gasoline as it is employed in motor work

It is true that the relation of speed to torque of a motor may be calculated as follows:

Let,

H.P. = Horsepower of the motor;
R = Radius of the lever arm;
S = Speed in revolutions per minute;
P = Pull in pounds at the end of the lever arm;

When,

$$P = \frac{\text{H.P.} \times 33{,}000}{6.28 \times R\,S}$$

Taking the case in point, the value of the torque at 600, 900 and 1,200 revolutions per minute is:

At 600 revolutions per minute:

$$P = \frac{34.3 \times 33{,}000}{6.28 \times 1 \times 600} = 303.2 \text{ pounds.}$$

At 900 revolutions per minute:

$$P = \frac{50.4 \times 33{,}000}{6.28 \times 1 \times 900} = 294.2 \text{ pounds.}$$

At 1,200 revolutions per minute:

$$P = \frac{64.8 \times 33{,}000}{6.28 \times 1 \times 1{,}200} = 283.6 \text{ pounds.}$$

Assuming that the best torque was realized at 600 revolutions per minute, which is a fair assumption, too, it is shown just how much the torque faded as the speed increased, but unfortunately it is not possible to state with certainty that this falling away of the torque is due to ills of carburetion; it may just as well be due to valve and other losses. It might be a reasonable statement of the situation that some of the falling is due to valve and other motor trouble and the rest to carbureter limitations, but it will be observed, nevertheless, that the performance is extremely good.

With a view to showing in a relative way the excellence of the performance as above referred to, reference may be had to Fig. 8, which is a speed and torque curve of a racing motor with a bore of 6 1-2 inches and a stroke of 6 3-4 inches, working 4-cycle, water-cooled. This motor was fitted with a Mercedes type of carbureter, was tuned up to the best point, delivering 66 horsepower at 1,000 revolutions per minute and a study of the chart would indicate that the power realized is none too satisfactory, due, to some extent, to poor ignition, but experience indicated that the mixture was not uniform over the whole range, which accounted for the falling torque.

The Effect of Time and Service Should Be Considered

The fault in the average record of the performance of an equipment is due to the fact that it is made under laboratory conditions. The effect of time and commercial service is not there reflected, and in this connection, referring particularly to carbureter work, there are too many chances against good commercial service, even though the laboratory situation may be something to whet enthusiasm.

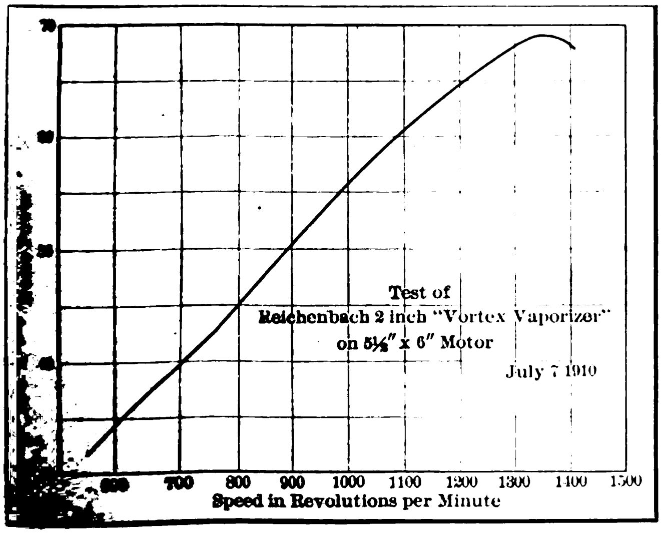

Fig. 7—Curve of performance of a Vortex carbureter on a motor

Take, for illustration, the surface indications as carbureters are used on automobiles in general. In some cases the refrigerating effect, which is produced by gasoline during vaporization, is indicated as frost upon the surfaces of the carbureter, and also over the cooler portions of the intake manifold. The average autoist very properly reaches the conclusion that heat is not being supplied to the vaporizing gasoline at a rate sufficiently high to prevent the lowering of the temperature down to the frosting point. But suppose there is no surface indication of this character. That fact does not prove that heat is being supplied to the liquid fuel on a basis to produce gas out of the same. It might be true, under such conditions, that the liquid fuel is not vaporized until it contacts with the highly heated surfaces within the combustion chamber with a small interval available to complete an operation that requires time.

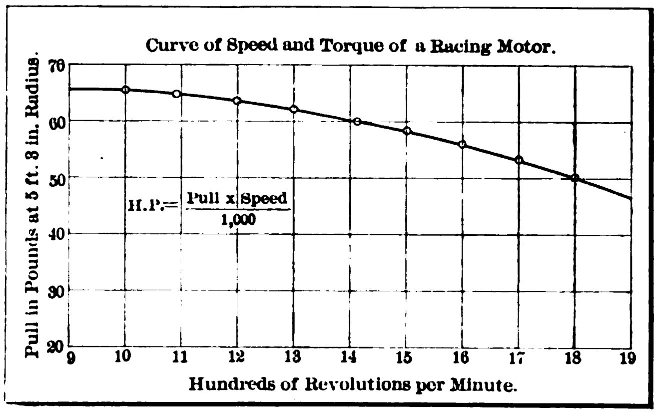

Fig. 8—Curve of torque and speed performance of a racing motor

Every autoist has a fair insight into the history and methods of the average charcoal burner, and it is quite well understood that he burns the wood in the absence of sufficient atmospheric air to produce a flame, and the product is in the form of charcoal. To tell autoists, however, that gasoline, if burned in the absence of sufficient air to produce complete combustion, also produces coke is to reach beyond their normal way of thinking. Fig. 9 is offered to serve as an illustration of the fact that liquids high in carbon will form coke under certain conditions, just as coke is formed out of wood. (A) Fig. 9 is a section of a coking oven on a small scale, the coke being in the hermetically sealed chamber at the top, the fire being made in the middle chamber, and the ashes from the burnt wood of the fire fall through the grate to the pit underneath. The oven at the top is primarily charged with wood, thereafter sealed and when heat is applied for a sufficiently long time the volatile matter is distilled out of the wood, leaving coke as a residuum. The reason coke forms lies in the fact that the chamber is hermetically sealed, thus excluding oxygen, and without oxygen the coke (carbon) cannot burn. (B) Fig. 9 shows the cylinder of a motor in section, with deposits of carbon adhering to the combustion-chamber surfaces and to the head of the piston. This combustion chamber in the cylinder of the motor is in every sense of the word a precise equivalent of the hermetically sealed chamber in the coking oven. When gasoline enters, if there is not enough atmospheric air with it to supply the requisite quantity of oxygen to burn the inflammable constituents of the gasoline, the portion that is deprived of its oxygen mate will remain in its original form. The inflammable constituents of the fuel are composed of carbon and hydrogen. The hydrogen is much more energetic in its search for any oxygen mate and burns first. The laggard carbon, in the absence of the right amount of oxygen, is therefore left in the lurch, and a part of it remains unattached, thus forming coke somewhat intermingled with lubricating oil, and the pasty mass spreads out over the adjacent walls, where it will remain until it is removed by mechanical means. Since there is about 83 per cent. carbon in the gasoline, it is not difficult to understand why carbon trouble becomes acute in automobile motors within a very short time if the conditions of carburetion are faulty.

In the Reichenbach Laboratory at 2420 Michigan Boulevard, Chicago, Ill., a series of tests were conducted for the purpose of ascertaining something of the facts in relation to the phenomena of carbureters. Fig. 10 presents one of the experimental devices that was rigged up to prove that gasoline would not vaporize when sprayed out of a nozzle, excepting when the conditions were such as to bring about the full heat exchange required to satisfy the latent heat of evaporation of the liquid, and the specific heat of the inrushing air. In this illustration C1 is the carbureter bowl, B1 is a base for the glass dome, P1 is the gasoline pipe leading through an orifice at the center of the base to the nozzle N1, which is scarcely discernible through the last dome, but is indicated by the dotted lines and an arrowhead. Suction is induced by the pipe P2, so that a depression is created in the glass dome, and, the latter being transparent, the nozzle action may be seen. With ordinary nozzles, and the suction that obtains under average conditions in automobile work, a stream of gasoline shoots up and splashes against the top of the dome. The more volatile portions fray out and form a mist around the solid stream, but the central core remains in continuous liquid form, which is proven by the force exerted as it splashes against the top of the glass dome and splatters down. It was found that by introducing a proper form of Venturi tube with tangential air passageways in juxtaposition to the nozzle a vortex was formed, and the solid stream as previously noticed no longer obtained. Instead of the gasoline streaming out of the nozzle, it formed in a spiral, attenuated sheet, with a certain separator action, so that the more volatile portions of the gasoline are free to rise and the resisting globules are thrown against the retaining walls with considerable force, where they are flattened out or shattered, thus rendering them more amenable to the further vaporizing process, and hastening the desirable action.

As a direct result of the series of experiments referred to, the vortex idea was incorporated into a carbureter, as shown in Fig. 11 in plan elevation and section.

Plan Elevation and Section of Model L Vortex Carbureter

In service, this carbureter performs as follows: Gasoline enters at E1, is controlled by the needle valve V1, which is pressed home by a spring S1, and when the gasoline falls below the level of the nozzle N1 the concentric float F1 drops down also until it rests on a lever arm L1, which has an upward projecting extremity E2 that presses against the action of the spring S1. These are all details that are not very different from carbureter practice in general, and the real matters to be enlarged upon are involved in the use of a detachable Venturi tube V2 with tangential air openings A1 and A2 located in the Venturi tube at a point somewhat below the top of the nozzle N1. A needle valve N2 is provided by means of which the gasoline flow from the float bowl to the nozzle may be pinched off or regulated. A catch basin B1 is located below the Venturi tube, concentric with the needle valve, with a means for vertical adjustment for the purpose of influencing the depression in the Venturi tube, and for the further purpose of catching a supply of gasoline which will pour into it when the motor is being started, thus facilitating the starting operation. Above the needle valve and the Venturi tube the mixture in passing contacts with a long thin water jacket wall J1, the water being in the jacket W1 and W2, entering at the orifice E3. Above the long water-jacketed wall there is a damper D1, by means of which the flow of mixture is more or less interrupted on its way to the motor through the manifold. Extra air is admitted through the snail-like passageway E4, and, referring to the plan, it will be observed that a rectangular gate G1 is placed over the orifice of the snail-like passageway E4, serving in the capacity of a clapper. The liquid gasoline as it resides in the float-bowl B2 is maintained at a substantially constant temperature, and heat is prevented from transferring from the surroundings to the liquid by means of insulation placed for the purpose, the idea being to maintain the liquid gasoline at a constant viscosity, thus regulating the flow of the same through the nozzle so that it will be constant for a given depression. It was found experimentally that the flow of gasoline through the nozzle into the depression chamber as formed by the Venturi tube was broken up into mist, due to the tangential action of the air sweeping through the passageways A1 and A2, and it was further ascertained that the less volatile particles were thrown up against the thin tube J1, to which they tenaciously adhered until, by virtue of the heat transfer from the water jacket, they were dissolved into a gas.

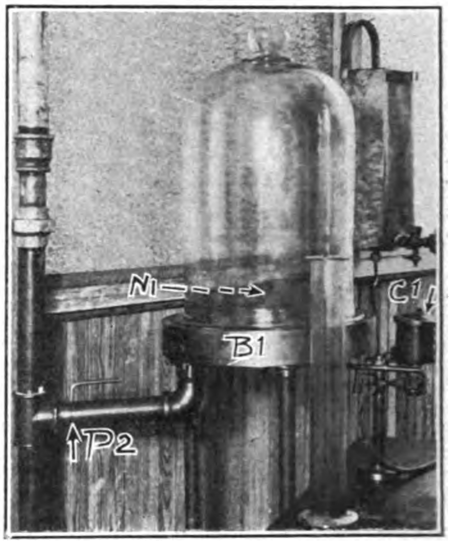

Fig. 10—Experimental equipment employed for the purpose of proving that gasoline does not vaporize at the nozzle of a carbureter

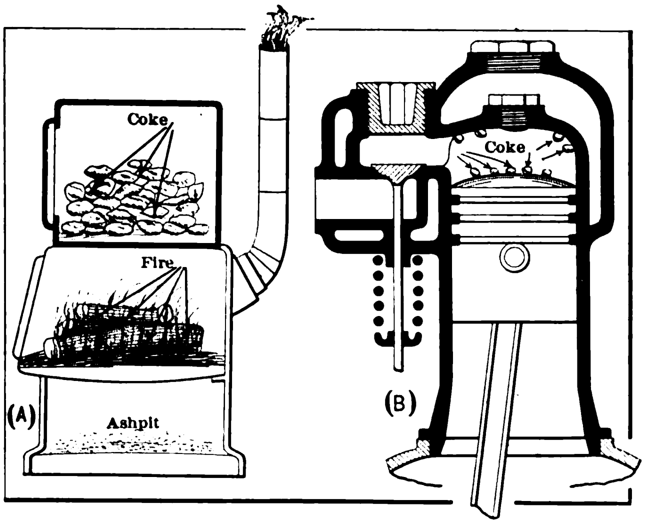

Fig. 9—(A) Section of a coking oven showing how coke is made; (B) Section of a motor cylinder showing how coke is made out of gasoline

Entrained globules of liquid gasoline that might get by the passageway formed by the tube J1 are taken up in the vortex generated by the auxiliary air which sweeps up by the clapper G1 through the snail-like passageway E4 into the space between the top of the tube J1 and the snubbing damper D1, and thrown out of the direct current of mixture against the walls W3, adhering thereto until these globules are dissipated in the process of forming gas.

It will thus be seen that the initial mixture, although it may be rich in gasoline, is nevertheless rendered dry, due to the swirling action of the air as it passes through the tangential passageways surrounding the gasoline nozzle, leaving the non-volatile globules adhering to the hot walls of the tube J1, and the rich mixture passes on engaging with the auxiliary air in

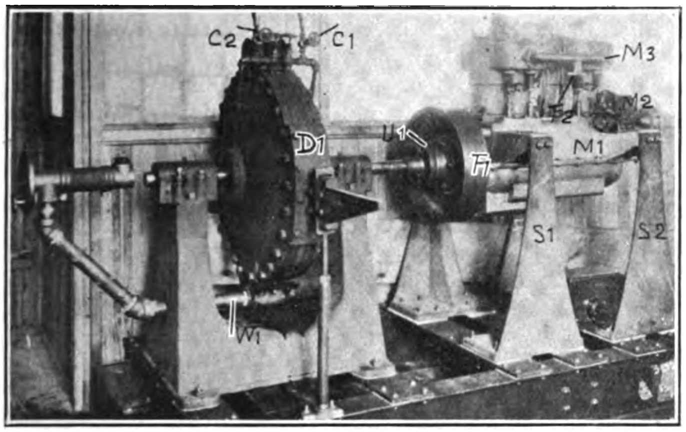

Fig. 11—Hydro-dynamometer designed for testing purposes in the laboratory used for proving the qualities of carbureters

the vortex chamber above. Owing to the lack of volatility of much of the liquid that now finds a resting place in automobile gasoline, it is to be expected that some of the liquid particles will work up into the vortex chamber before they are completely dissolved, but they will be there swept with considerable force against the retaining walls, where they will be shattered by mechanical battering, and will drop down onto the hot platform below, there to remain until the gas formed out of them will tell the tale of their complete annihilation.

The one remaining consideration of unusual purport lies in the means of adjusting the clapper G1 over the orifice of the snail-like passageway E4. This is brought out clearly in the plan showing a contoured finger F2 in rigid relation with the shaft to which the clapper G1 is also rigidly attached, so that when pressure is applied to the finger F2 the clapper G1 is forced open. Force is applied to the finger F2 by means of the bell crank B3, which in turn is actuated by a spring S2 pressing against one arm of the bell crank B3 at one end, and an abutment A3 with an adjusting screw A4, having a knurled head, which if turned in one direction puts tension upon the spring, and vice versa. The object in having the finger F2 suitably profiled along its face is to facilitate the action involved in opening the clapper G1. When the carbureter is running, furnishing a rich mixture, as when the motor is being started, the extremity of the bell crank B3 presses against the point P1 of the finger F2 and the clapper G1 remains substantially closed. As a further means of adjustment the slot S3 permits of moving the base piece B5 in or out with a set-screw S4 available for locking. The effect that this in-and-out movement of the base piece induces is to alter the line of pressure of the face of the bell crank B3 where it engages the face of the finger F2 and in this way the opening and closing of the clapper G1 is made early or late as the exigencies of service would seem to demand. As the clapper G1 opens, the line of contact between the finger F2 and the bell crank G3 shifts in the direction of the extremity of the finger F2, and is shown at P2 in the plan. The adjustment is extremely delicate, and is rendered permanent by the means afforded, so that having set the carbureter in the position of rich mixture for starting, the various other mixtures are obtained automatically over the complete range of performance of the motor, up to the limit as shown by the curve of motor performance presented elsewhere in this article.

In order to be able to test this type of carbureter under conditions of actual service, it was applied to various automobiles and as the result of these practical trials an insight was gained into the mechanical shortcomings of the original design, but simultaneously a series of laboratory experiments were conducted, and it was finally decided to install a dynamometer as shown in Fig. 11 for testing purposes in which M1 is the motor, M2 the magneto, S1 and S2 the stands, F1 the flywheel, U1 the universal joint connection and D1 the dynamometer, with its water entrance W1 at the bottom, and means of control C1 and C2 as shown. The carbureter manifold M3 is of the ordinary type and the carbureter to be tested is bolted to the flange F2. This form of dynamometer affords the means of operating carbureters under a wide variety of conditions, giving the range of performance degrees of flexibility, and indicating with great clearness the dead points as they obtain in carbureters in general.

As the direct result of a long series of investigations, utilizing the most advanced facilities, and persisting, the Reichenbach Laboratories Company arrived at the conclusion that the Vortex carbureter is in conformity with the best requirement, satisfying the principles as hereinbefore enumerated to the exclusion of the troubles so clearly brought out.

Effect of Kinetic Forces on Motors

In view of the presence of reciprocating and rotating parts in a motor, the movements of the parts will set up in the members a system of forces on a kinetic basis. The members that are most responsible for these forces are: (a) the piston, (b) wrist-pin, (c) part of the weight of the connecting rod. Variations in the frictional effort as the piston travels in the bore of the cylinder will also have some influence toward generating secondary moments which may be assigned to the reciprocating class owing to the fact that these variations come on account of the travel of the same. But if the variations of friction have to be considered, it follows that variations of gas pressure and of back pressure will also have to be taken account of.

The manifestations of these hidden forces comes in the form of a modification of the angular velocity of the crankshaft and the flywheel. There will also be a system of unbalanced forces acting upon the frame of the motor. The rotating members as crankshaft, flywheel, camshaft, half-time gears, etc., will induce similar rocking effects, depending upon design, weight, speed and condition of lubrication, but they will not be so marked as those effects which are induced by unbalanced reciprocating masses.

The kinetic forces, under the circumstances, may be divided into two classes: (a) reciprocating and (b) rotative. In a sense, the connecting-rod forces belong to both classes; these members not only reciprocate, but they rotate as well. In the solution of

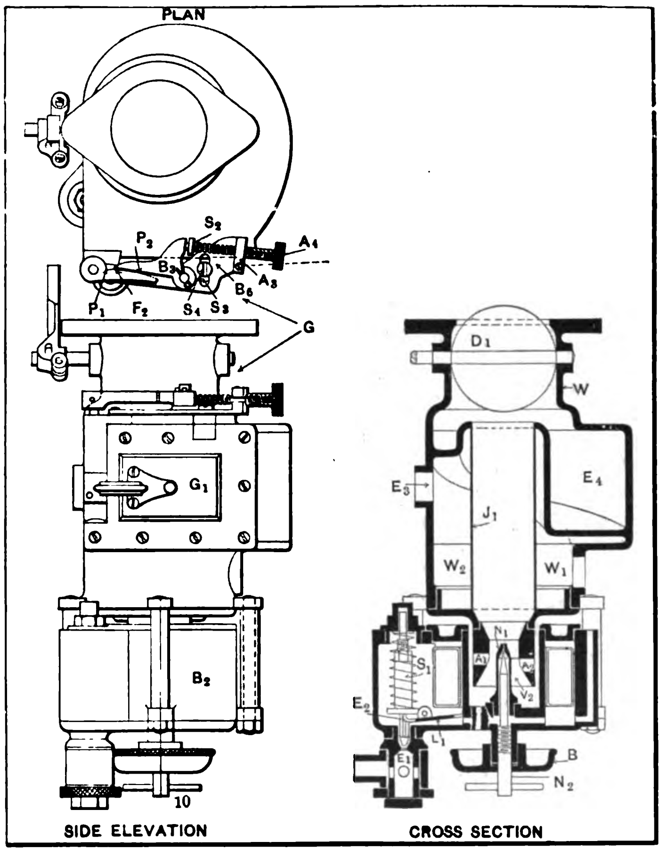

Fig. 12—Plan, elevation and section of the Vortex carbureter showing the Venturi tube, tangential ports and snail-like chamber

the problem invoking the extent of the rocking of the frame and other vibrations set up, it is necessary to attack the matter from four points of view as suggested by Professor Dunkerly, i. e., (a) solve for the resultant force to give the rod its combined motion, (b) plot the inertia of the connecting rod on the cranking-effort diagram, (c) solve for the displacing force on the frame, and (d) determine the bending force on the connecting-rod due to its own inertia.

Should it be desired it is possible to solve for the equivalent inertia forces at the wristpin, it is a choice which adds but little complication, and certain advantages are present in the plan. At all events, in the final sum up, it is necessary to fix the turning moment, rocking effect on the frame and the stresses in the members, in order to proportion their sizes with safety, or forecast the amount of rocking so that it will be possible to decide as to the desirability of changing the form if there is too much to tolerate.

In designs as they obtain, it is barely possible that the greatest mistake comes from assuming that a good static balance of the members is of the first importance. It is quite possible to have a condition of good static balance and an augmented display of kinetic trouble in consequence. In such cases it is better to depart from a condition of perfection static balance enough to correct the kinetic conditions to obtain the best average result.

If a tire is below size it will not inflate to roundness under any pressure that can be applied.

Composition of Steel and Permanent Magnets

To make permanent magnets that will do just as good work as can be accomplished when the magnets of a generator are wire wound, it is necessary to employ a grade of steel that will deliver a high flux density and hold the property termed "retentivity" to a marked degree. It is unfortunately true that most grades of steel, when they are subjected to the hardening process, afford but a low flux density and are only partially retentive. Plain tool steel, while it will serve for this class of work, is not nearly so efficacious as some of the grades of alloy steel, and of the alloying elements available tungsten seems to be best. The very latest practice in Germany involves the use of tungsten, but the steel is made in the electrical furnace and the carbon is well regulated. In addition to this the material is rendered of high specific gravity, which is one of the claims for electric furnace steel. The composition of this particular brand of steel is as follows:

Chemical Composition:

Tungsten	6.00 per cent	Silicon	.20
Carbon	80 points	Sulphur	.03
Manganese	80 points	Phosphorus	.015

Just why the electric furnace is the most appropriate for the turning out of magnet steel is a matter that will have to be disposed of after some study, but it is important to note that there is quite a difference in the structural appearance of steel made in this way as compared with products of the crucible pot, or from the open hearth.

New Carbureter Principle

ILLUSTRATING A NEW IDEA IN CARBURETION INVOLVING THE USE OF A DIFFERENTIAL COMPENSATING VALVE AUTOMATIC IN ITS ACTION WITHOUT INTERFERING WITH HAND-CONTROL

RECOGNIZING the utter impossibility of anticipating the needs of a motor from the mixture point of view, many designers have struggled with the automatic carbureter problem. It would be a simple undertaking to supply mixture to a motor were it to run at a constant speed and under a fixed load. This cannot be true in automobile work, for the reason that the power required depends upon the speed at which the car is driven, and upon the road conditions. Even if the road were to be level and hard, thus eliminating troubles from this source, the carbureter problem would still be complicated, due to the fact that wind resistance intervenes; nor does the power required increase in direct proportion.

Strictly automatic types of carbureters have been designed, involving many mechanisms, and while they offered advantages more or less desirable, they nevertheless fell short of the exacting needs, so that the substitution of automatic means of control for hand-control had the force of swapping one set of troubles for another.

That the average motorist takes more kindly to hand-control carburetion than he does to the automatic system is believed to be true. This preference is due to the fact that while hand-control is prone to introduce dead spots in the range of carburetion, and shows the effect of lack of dexterity on the part of the operator, it eliminates the impossible condition which creeps in under automatic conditions when the range of performance of the automatic device falls short of the indicated requirement.

During the past two or three years autoists have complained of carbon trouble on an increasing basis, and they jumped to the conclusion that excess of carbon in the cylinders was due to some fault in the lubricating system. This idea led to the investigation of the lubricating oil problem, until to-day it is the practice of the average autoist to purchase the best lubricating oil that can be had, and to use it so sparingly as to risk damaging the motor as the direct result of restricted lubrication. It is now a fairly well-established fact that the amount of carbon that is likely to sift out of the lubricating oil and form a crust over the combustion chamber surfaces is too infinitesimal to merit serious consideration.

Before departing from this question of the troubles due to lubrication, it will be proper to state that the best possible performance will come if lubrication is profuse and with the understanding that the lubricating oil supplied will be suitable for the purpose. The fact that the lubricating oil is not at the bottom of carbon trouble does not afford a license for using the kind of lubricant that will crack under the conditions of operation involved. It will be understood, of course, that when lubricating oil does crack carbon will be precipitated. If it may be stated with certainty that the carbon troubles which motors seem to fall heir to are for the most part, if not entirely, due to poor mixture, it goes without saying that a proper remedy lies in the use of suitable fuel and a carbureter that will afford a mixture that will burn completely. The product of combustion, if carbon is to be kept from forming, must be nitrogen, carbonic acid and water. The nitrogen, being an inner gas, enters with the atmospheric air, and comes out unchanged. This part of the mixture, then, is a mere diluting agent, and since it leaves just as it enters it does no harm whatever, provided it is present in just the quantity required. In further relation to this content, it is pointed out that the gas engineers who claim that nitrogen is detrimental labor under the false impression that the mixture would be much more powerful were it not diluted with nitrogen. This contention is based upon fact, but it does not necessarily follow that the performance of a non-nitrogenous mixture would be satisfactory in a motor. The best performance comes when the rate of flame travel in the mixture is slow enough to permit the piston to sweep ahead of the wave of pressure at a certain rate. Referring to Fig. 1, which is a diagram of compression, ignition and expansion, presenting the idealized Otto

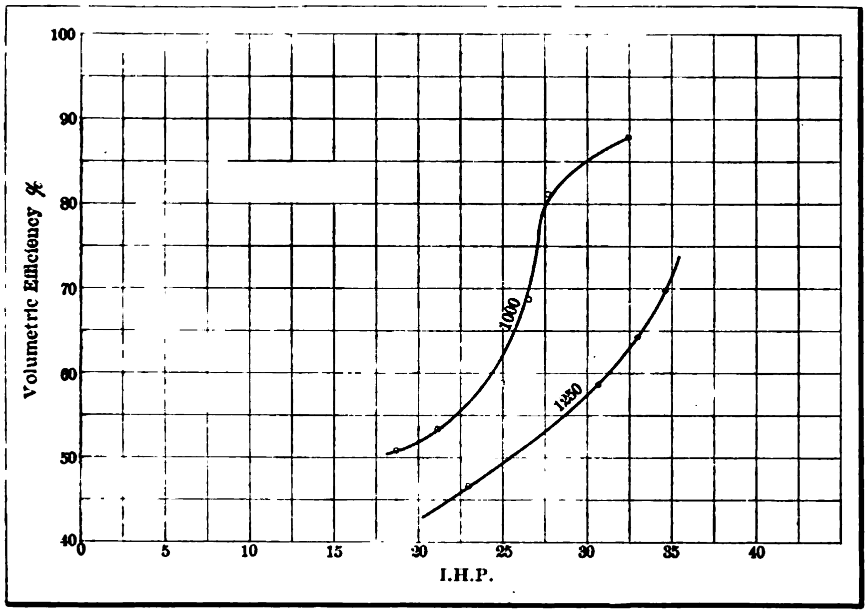

Fig. 3—Chart contrived for showing the changes in volumetric efficiency under changing loads with two different speeds

cycle, it will be observed that the ignition line 2 3 is straight. When the ignition takes place with sufficient speed to afford a straight line, then the rate of flame travel of the fuel after ignition is high enough to serve every proper purpose. That there should be no burning of the fuel during the expansion stroke is shown in this diagram, and is accepted as an established fact in practice. What is wanted, then, is the greatest possible filling of the cylinder during the suction stroke, which will be true if the inlet valves are large, the piston rings tight, and the cooling conditions are such as to maintain a constant and sufficiently low working temperature. With these conditions established, compression will take place on the compression stroke 1 2, ignition will follow, preserving the straight line 2 3, and expansion will take place without burning 3 4, all in Fig. 1. The exponent n_1 is given as 1.31 in the expansion curve, which represents a sufficiently high value of this exponent to indicate somewhat better working conditions than can be expected when the carburetion is poor. Confining the discussion to the merits of nitrogen, for the moment, it is pointed out that it seems to be in about the right presence for the proper dilution of well-contrived mixtures, and it is also worthy of note that it is not the nitrogen that produces trouble when the mixture is poor.

Fig. 2 shows six indicator cards, which are characteristic of the performance under six sets of conditions, as follows:

(*a*) When the ignition is 25 degrees early;
(*b*) with the ignition 20 degrees early;
(*c*) with the ignition 16 degrees early,
(*d*) with the ignition 12 degrees early;
(*e*) with the ignition 5 degrees early.
(*f*) with the ignition 10 degrees late.

The card *d*, Fig. 2, is a good practical representation of what might be expected under normal conditions with good carburetion and with the ignition taking place while the piston is on the top dwell point, so that there is no burning during the expansion stroke. It will be seen, from a study of these cards, that the ignition problem must be properly cared for if the questions of carburetion are to be discussed intelligently, and with the understanding that the ignition will be on a basis of merit; if it is also assumed that the question of nitrogen in the mixture is one that can be set aside, it will then be proper to discuss the further problems which arise in this connection.

Properties of Gasoline and Other Hydrocarbons

Remembering that nitrogen is of the air, and in sufficient presence to serve for dilution purposes, the next step will be to consider true gasoline, which product has a specific gravity ranging between 0.680 and 0.710, with a boiling point as low as 140 degrees, and maximum at 158 degrees Fahrenheit, the chief constituent being hexane, the formula for which is C_6H_{14}. For perfect combustion each kilogram of gasoline requires 11.8 cubic meters of air, so that the proportion of liquid and air under conditions of perfect combustion is in the ratio of 12.4 to 100,000. It will be the same result, if 2.15 per cent of the total volume of mixture is represented by the vapor of gasoline as above constituted.

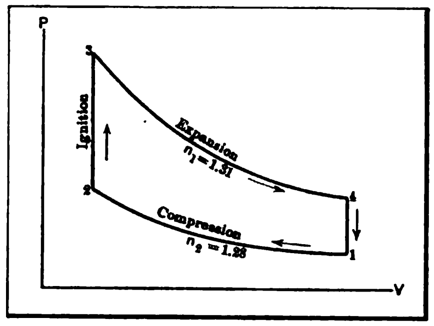

Fig. 1—Idealized Otto cycle, showing compression, ignition and expansion lines

There are two considerations that stand in the way of the realization of the best possible results, and the first of which lies in the fact that "automobile gasoline," which is the product available at the present time, differs from the true mixture as above outlined, and the second difficulty takes into account the variations that creep in when speed and load change. Were the speed to remain constant, and the load to change, that consideration would resent one phase of the problem, and should the load change and the speed remain constant, a second phase of the situation would be recognized, but unfortunately, in practice, both the speed and the load change simultaneously, which, together with the fact that the gasoline to be had is not uniform, adds very materially to the carbureter problem. Automobile gasoline, instead of being a single distillate, as hexane, is substantially composed as follows: Hexane, with a specific gravity of 0.676; pentane, with

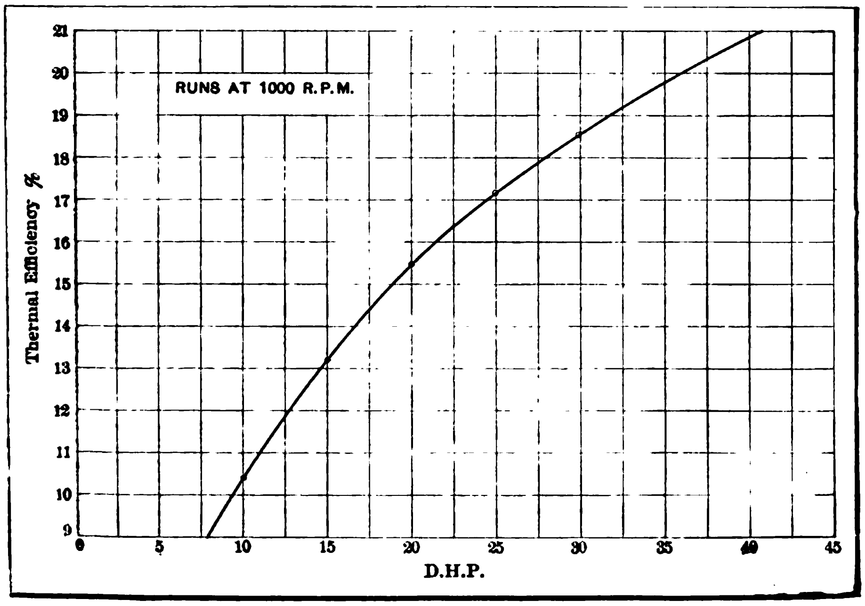

Fig. 4—Chart designed to indicate thermal efficiency under different loads at constant speed

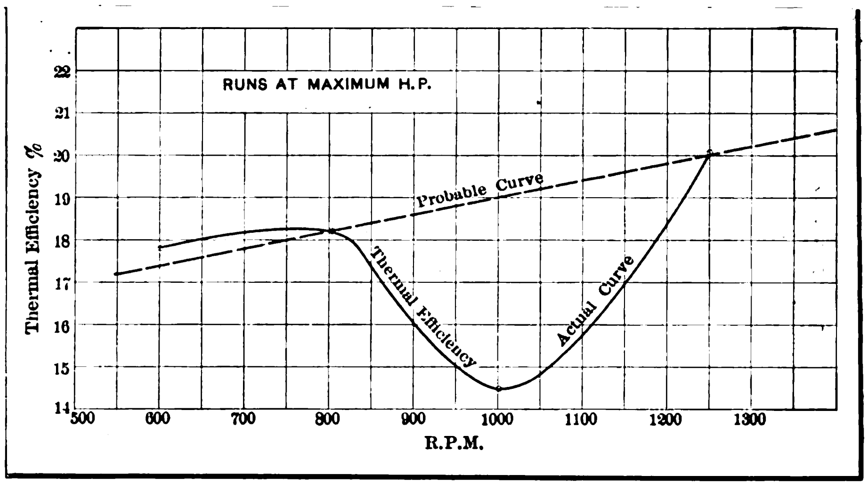

Fig. 5—Plotted to depict the variations in thermal efficiency at a maximum load, speed changing

a specific gravity of 0.640, and heptane, with a specific gravity of 0.718. The proportions by weight, considering a good grade of automobile gasoline, which is far from a good grade of gasoline proper, may be as follows: Pentane 2 per cent, hexane 80 per cent, and heptane 18 per cent; total, 100 per cent.

It is highly improbable that the available supply of automobile gasoline of the above composition is equal to the present requirement, and it is more than likely that octane, nonane, and even decane, will be found in much of the liquid fuel that is now sold over the counter. In proportion as the last three named distillates are introduced, hexane is left out of the mixture, and the volatility of the product as a whole falls off rapidly as hexane is eliminated.

The proportion of carbon in the typical automobile gasoline above named is 83.8 per cent, 16.2 per cent is hydrogen, and 3.5 pounds of air must be added to make the theoretically right mixture.

There is a great difference between figuring the theoretically right amount of air for complete combustion, and trying to find out how much air must be used under the conditions that obtain in practice. That there must be an excess of air is a recognized fact, and just how much excess there will be, when the conditions are most satisfactory, is almost beyond an estimate. All the variables mentioned have bearing upon this phase of the problem. Moreover, the excess of air must increase with increasing compression; in other words, a high compression motor requires a greater excess of air than that which will satisfy a motor with a lower compression, but, unfortunately, the actual compression in any motor varies with the speed of the same, and is affected by other considerations, as scavenging, which in turn is a variable depending upon some thermal considerations, back pressure offered by the muffler, the extent to which the carbureter serves as an obstruction in the intake, etc.

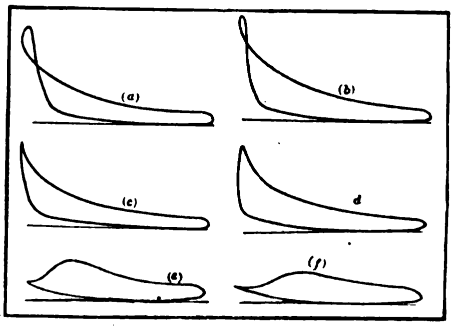

Fig. 2—Six indicator diagrams showing how the card varies with different ignition points

Carbureters Frequently Obstruct the Intake

It is one of the misfortunes in automobile motor work that the amount of gas which is permitted to enter the cylinders is below the best requirement, and, as Fig. 3 shows, the volumetric efficiency resulting is not only low but variable as well. In this chart, the abscissæ read horsepower and the ordinates are given values in per cent. of the volumetric efficiency. By volumetric efficiency is meant the extent to which the cylinder of a motor is filled with gas during the suction stroke to a point where the suction line crosses the line of the atmospheric pressure. The average layman may have difficulty in appreciating just what this means, but there is one fundamental point that should appeal to him, and perhaps by using a parallel the idea may be more forcefully introduced. For instance, the amount of heat that will be given off by the radiator system in the reader's own house will never exceed that which is represented by the heat units in the coal that is shoveled into the furnace. In the same way, the amount of power that can be taken from an automobile motor can never be greater than the amount of heat (minus losses) that is represented in the gas which is introduced by suction methods into the combustion chamber of the motor. In measuring the volumetric efficiency of a motor, it is a simple and comprehensive process by which the fuel is weighed, and if the amount of fuel utilized is below a fitting requirement, the thermal efficiency as measured in per cent will also be low. In determining the thermal efficiency of a motor, a manograph card is taken, and tracing the suction pressure, which is below the atmospheric line, will bring to notice the fact that this suction line crosses the atmospheric line at some point in the stroke. If the volumetric efficiency is said to be 70 per cent. then at a point 30 per cent. down on the suction stroke the line of suction pressure will cross the atmospheric line. The process involved, if a manograph is available, is very simple and reliable. Referring again to Fig. 3, there are two curves plotted, one of which is at 1000 revolutions per minute and the other at 1250. This chart very clearly indicates that the compression must have been lower at 1250 revolutions per minute than it was at 1000. Delivering 30 horsepower, the volumetric efficiency was 57½ per cent at 1250 revolutions per

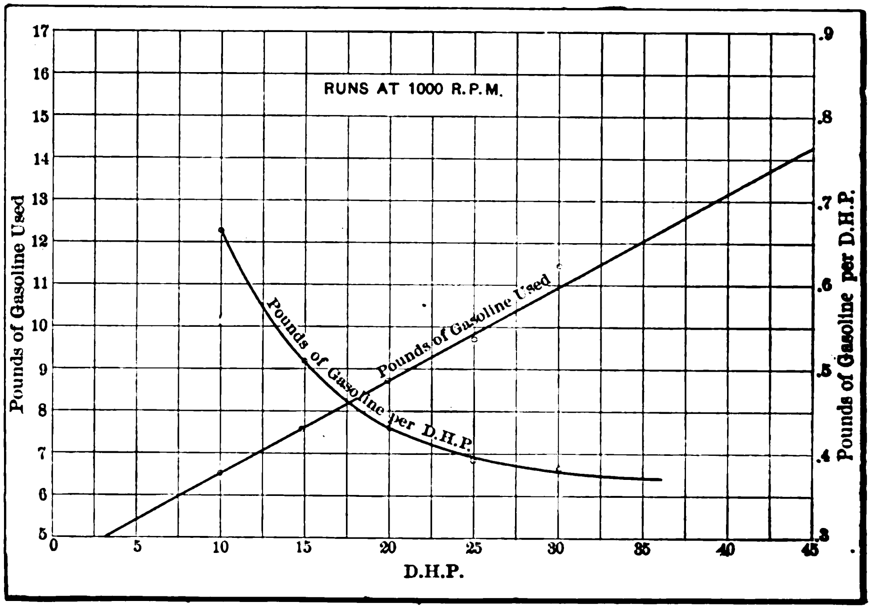

Fig. 6—Charted consumption of gasoline at a constant speed with varying load

minute. Delivering 30 horsepower at 1000 revolutions per minute, however, the volumetric efficiency was increased to 85 per cent. It stands to reason that the motor was doing more efficient work at 1000 revolutions per minute delivering 30 horsepower than it was when it delivered the same horsepower at 1250 revolutions per minute. True, the power was the same in both cases, but the amount of gasoline required was considerably greater at the higher speed.

When the volumetric efficiency of a motor is lowered by increasing speed, even assuming the power delivered is the same as at some lower speed, the thermal efficiency falls off with the decreasing volumetric efficiency. Just how the thermal efficiency varies with horsepower at a constant speed is shown in Fig. 4, in which the delivered horsepower is represented by ordinates, and the thermal efficiency in per cent. is shown on the scale of abscissa. This particular motor showed a thermal efficiency of 18.6 per cent at 30 horsepower and 1000 revolutions per minute.

By thermal efficiency is meant the percentage of the total heat units available in the fuel that are turned into useful work. When the thermal efficiency is 100 per cent all the heat units in the fuel will be turned into useful work. The best thermal efficiency available in steam practice ranges between 8 and 16 per cent, whereas the best thermal efficiency in internal combustion motors ranges between 12 and perhaps 22 per cent. There are a few isolated instances of a better thermal performance of certain types of internal combustion motors, but it is not believed that automobile types of internal combustion motors reach beyond 22 thermal efficiency. This is a very high value, however, and it is one that is never reached in actual practice, owing to the imperfection of carbureters and wide variations in the actual load as well as speed variations of the motor. Just to show how speed changes affect the thermal efficiency, under conditions of maximum load of a motor, Fig. 5 is given in which speed is represented by ordinates, and the thermal efficiency is given in per cent, on the scale of abscissa. In this case, the dotted line, representing probable curve, differs from the plotted curve, due to influences which were beyond the ability of the testers to observe. If the dotted line of probable performance is taken as true, the thermal efficiency was 17.3 per cent at 600 revolutions per minute, and increased to a point slightly above 20 per cent at 1250 revolutions per minute. This curve was taken from a Franklin air-cooled motor, during a series of tests which were made under the direction of Professor Rola C. Carpenter, Sibley College, Cornell University. For the purpose here, it serves every end, and while the actual thermal values might move up and down the scale more or less, depending upon the motor used, the fact remains that the thermal efficiency is not constant with variable speed and fixed load. nor can it be constant with variable speed and variable load.

There is one other point that must not be lost sight of in considering these curves. The tests were made in a laboratory with instruments of precision of every kind available, and they were conducted under the direction of Professor Carpenter, who also had at his disposal a large number of trained assistants, so that the tests were all run after the motor was carefully tuned up, and the records taken were those showing the best obtainable results, which means that the carbureter was hand-adjusted, and manipulated until it showed its maximum capability. On the road, under normal working conditions, there is no method available by which the driver of a car can tell when the carbureter is properly adjusted, nor would he be able to anticipate the varying conditions of service, so that it would be impossible for him to realize anything like the results as shown in these curves.

As a further illustration of the fact that the thermal efficiency, when observed, reflects with exactness the consumption of gasoline per horsepower, or per car mile, as the case may be, reference may be had to Fig. 6, which is also one of the curves plotted under the direction of Professor Carpenter at Sibley College. In this case, the delivered horsepower is represented

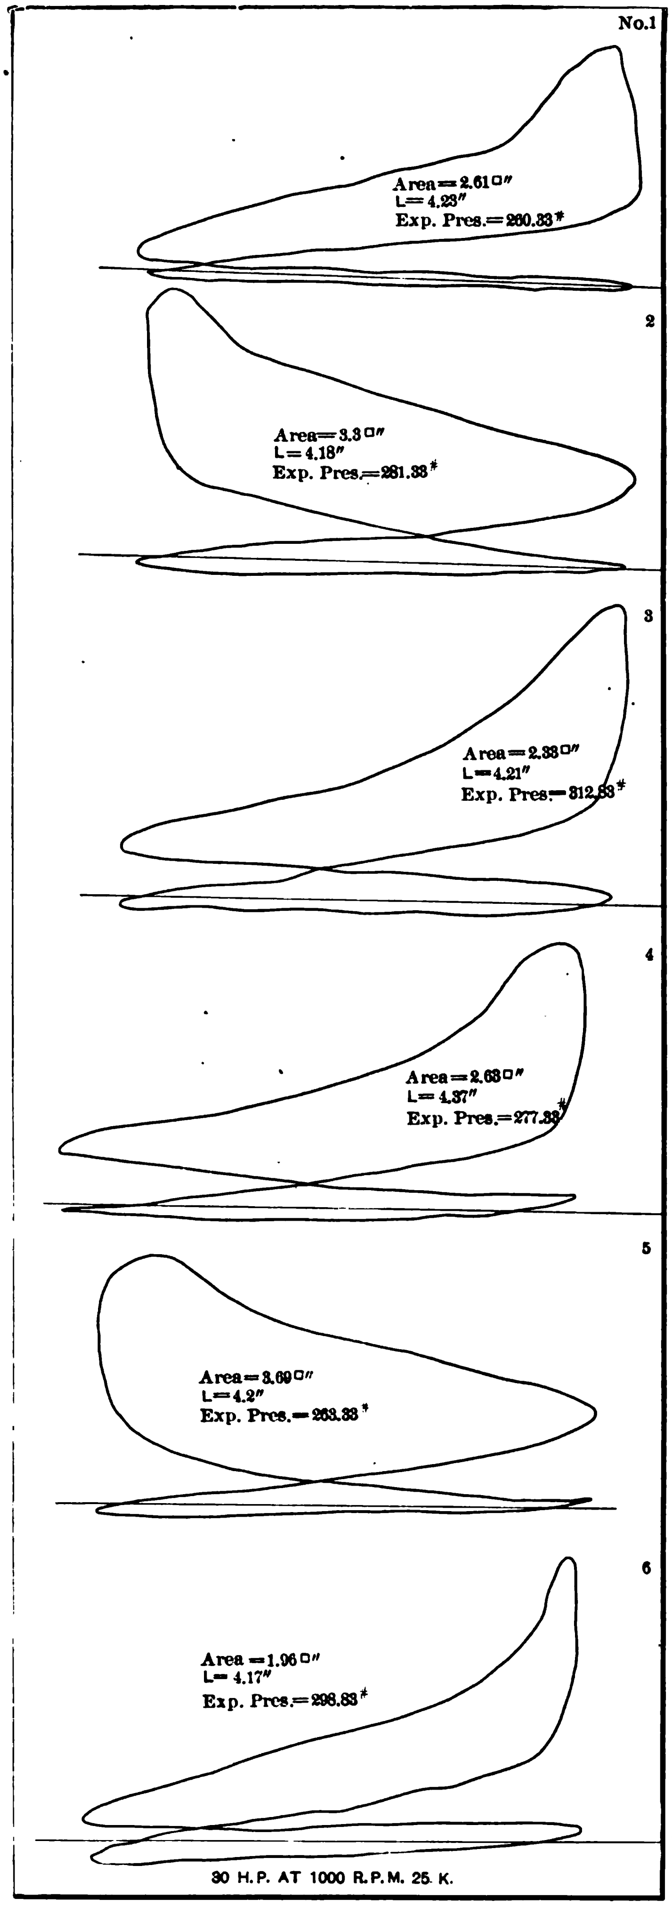

Fig. 7—Six indicator cards taken from a 6-cylinder motor showing changes in expansion due partly to poor carburetion

by ordinates, and the gasoline consumption in pounds is stated at abscissa. The motor was run at 1000 revolutions per minute, and two curves were plotted. The curve representing pounds of gasoline per delivered horsepower (D.H.P.) shows that the most economical consumption was when the motor was delivering about 35 horsepower, and the most extravagant consumption was when the motor was delivering 10 horsepower.

Lack of Uniformity Partly Due to Carburetion

It will be understood that a motor with a plurality of cylinders will not deliver a fixed amount of power, the same in each, unless the means for carburetion are such as to supply to each of the respective cylinders an exact measure of a given quality of mixture. That carbureters do fail in this important particular is readily shown by referring to Fig. 7, which represents indicator cards taken from the six cylinders of a motor. The carbureter is not entirely at fault for the variations here noted, but that carburetion represents the greatest measure of the total trouble there is no gainsaying. At all events, in this case, the expansion pressure was found to be as follows:

EXPANSION PRESSURE IN THE RESPECTIVE CYLINDERS

Expansion Pressure in pounds per sq. inch	Cylinder Number
260.33	1
281.33	2
312.83	3
277.33	4
263.33	5
298.83	6

With such wide variations in the expansion pressure, it is impossible to expect that each of the cylinders will deliver its quota of power on a basis of equality. Under such conditions, it is impossible to say that a six-cylinder motor, for illustration, will deliver as much power as six single cylinder motors of the same size, operating under substantially the same conditions. If this is not true, then it stands to reason that there is a disadvantage attached to having a plurality of cylinders, so that granting the desirability of employing four or six cylinders in a motor, it is equal to saying that the conditions of carburetion must be maintained on a basis that will assure to each of the cylinders its fair measure of the total mixture. This phase of the problem, while it has been recognized as one to be coped with by the makers who are equipped to observe the facts, is nevertheless far from sufficiently treated for the reason that it has been found difficult to so design carbureters that they would respond to the demand.

The Rayfield Principle Offers Serious Possibilities

In the Rayfield carbureter, as manufactured by Findeisen & Kropf, Chicago, Ill., the principle involved takes into account two important considerations, one of which is that the amount of fuel required must be varied, depending upon the speed and power of the motor, and the remaining feature lies in the use of an automatic air valve that will operate for the purpose of supplying air when hand-control fails. The exterior appearance of this carbureter is shown in Fig. 8. It is of the float-feed type, compact in form, and of pleasing appearance, mechanically designed on a stable basis, so that adjustments when once made will remain so.

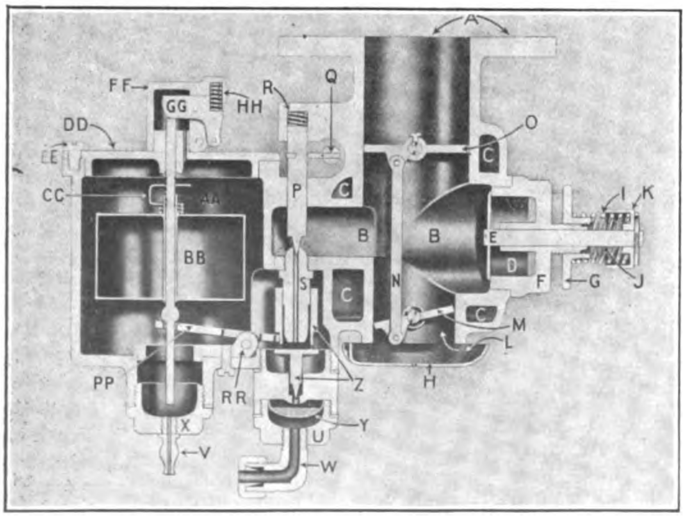

Fig. 9—Cross section of the Rayfield Carbureter bringing out the advantages of a differential compensating valve in conjunction with hand-control

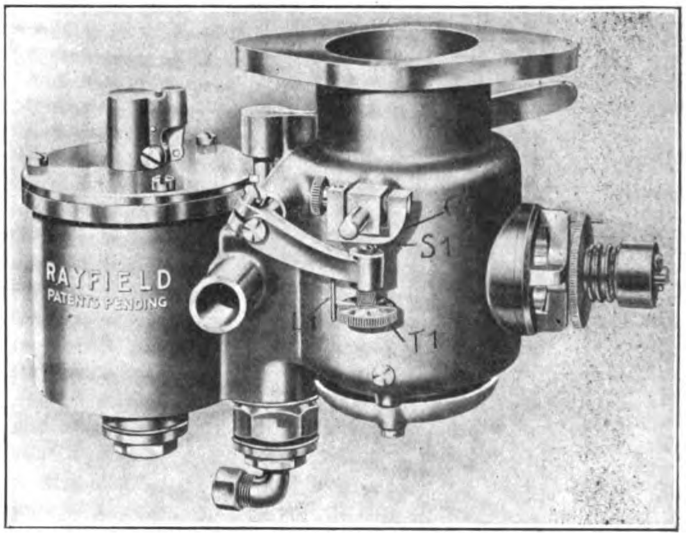

Fig. 8—Exterior view of the Rayfield Carbureter showing the method of adjusting to obtain the best result

To understand the working of this carbureter, it will be necessary to examine the section Fig. 9, while following the description as follows:

Gasoline enters through the fitting W, and its mate U is filtered by the screen Y, and is stopped off by the needle Z, which has a German silver tip, engaging a suitably contrived seat. To stop the flow of gasoline, the float BB in the chamber AA, if properly set by the adjusting spring CC, will raise high enough to free the lever arm PP, thus permitting the part Z, to which the tip of the needle is fastened, to fall by its own weight so that the needle will seat. The nozzle S is concentric with the dashpot-like member Z, and the gasoline is stopped off by the auxiliary needle P, which is pressed to its seat by a spring R, but is lifted off its seat by a bell crank Q, which is controlled through a cam motion, operating when the damper O travels a certain distance. Simultaneously with the damper O the damper M travels, being actuated by the link N, and as these dampers open air is admitted through the space L above the rim of the catch-basin H, filling the cavity B. In starting the motor, a small amount of air passes in through a fixed opening, which is shown by a dotted line surrounding the nozzle S. This air sucks up enough gasoline to make a rich mixture, and this mixture passes into the chamber B, and through a slit in the damper O. The operator, desiring to speed up the motor, alters the adjustment of the damper O, simultaneously lifting the auxiliary needle T and the damper M. The result is a supply of mechanically established mixture, which, under ordinary conditions will suffice for the purpose, and to this extent the carbureter is in accord with the best practice from the point of view of mechanically controlled carbureters of the auxiliary air type.

If, for any cause, the mixture becomes unbalanced, the differential compensating valve E, which is under the control of the spring I, holding the valve to its seat, being supported at one end by the cap K, with means for adjusting its tension by way of a threaded member G, the valve E will open and supply the requisite quantity of undiluted air to bring about a readjustment of the gasoline ration in the mixture, so that if the mechanical adjustment is such that the mixture is too rich, provided the speed of the motor is increasing, the valve will open and permit of the introduction of enough air to render the mixture sufficiently lean to do the most efficacious work.

But should the mixture be too lean, the speed of the motor will decrease, in which event the differential compensating valve will close automatically, and by doing so bring about a condition of enriching of the mixture, with the result that the speed of the motor will become stable, and the power will be that which should obtain when the mixture is exactly right in view of all the operating conditions.

The secret of success of this carbureter lies in the fact that the operator is permitted to exercise his ingenuity to the extent of his ability in nursing the carburetion in response to the indicated motor and road conditions, but should the conditions alter at a rate greater than the ability of the operator to cope with them, the differential compensating valve instantly supplies the missing quantity, either diluting the rich mixture, if the speed increases, or stopping off the air supply if the speed decreases.

The remaining details are purely constructive, and unimportant from the point of this story. It will be observed, however, that the adjustment CC represents a simple and stable means by which it is possible to raise and lower the float level, if the occasion arises. As a further mechanical refinement, the bell crank GG depresses the float BB by pressing on the end of the float stem if it is necessary to time the motor in starting. The bell crank GG, however, is prevented from working excepting at will by the spring HH, which is sunk in a cavity in the metal. The housing FF covers over the mechanism so that when the car is being washed, or during inclement weather, water is not permitted to seep through and contaminate the gasoline.

In the operation of the carbureter there is only one adjustment to make, and that is for low speed. This undertaking is much simplified through the use of a thumb nut T1, the screw end of which, S1, bears against the face of the cam C1 in Fig. 8.

A means for locking, L1, maintains the adjustment of the thumb nut after it is made, and it is this adjustment that fixes the flow of gasoline in accord with the low speed requirement. At all other speeds, the rate of flow of gasoline is maintained by movement of the auxiliary needle P, Fig. 9, and a skilled operator, if he cares to do so, may then take advantage of the presence of the differential compensating valve, adjusting it with a view to further refinement in the range of performance of the motor.

Don't

STILL ANOTHER INSTALLMENT OF SHORT-METER ADVICE TO THE TYRO—AND THE EXPERT—THE FOLLOWING OF WHICH MAY SAVE THE MOTORIST HEAPS OF TROUBLE, PERHAPS SOME MONEY, AND PROBABLY A LAWSUIT OR TWO

Don't think that it is possible to blow up tires sufficiently to compensate for the lack of size that should be used on your car. If the tires are not big enough for the work they are placed to do it is not possible to inflate them sufficiently to prevent excess flexure.

Don't get used to thinking that fabric as it is used in the making of tires is some supernatural material that will stand all sorts of abuse—it costs money and plenty of it to indulge in such a dream.

Don't forget that flexure is the bane of tires—anything that will eliminate flexure is worth its weight in gold.

Don't forget that a power pump is far more likely to afford the requisite pressure for purposes of inflating tires than when a small hand pump is employed.

Don't run on a flat tire just because it is something of a job to make a road-side repair—10 miles of flat running will foot up to the price of a tube and a casing; even a single block may be a sufficient distance to bruise the fabric beyond repair.

Don't wait for the ball bearings in the hubs of the road wheels to go to pieces before taking the hub-caps off and determining as to the prevailing condition. If the bearings are flushed out once a month and new grease is applied the cost of maintenance will be relatively very low.

Don't let the repairman tell you that he is going to burn off all the old finish and refinish from the ground up, and then let him get away with a retouching job instead—a little superintendence once in a while does no harm.

Don't let water accumulate in the fuel system. Drain out all the liquid, say, once a week, and start with a new gasoline supply.

Don't demand the last ounce of power from your motor; it will last longer if it is worked under average conditions.

Don't feed gasoline too fast; carbon accumulations will then be deferred, if, indeed, they ever appear.

Don't expect gasoline to feed through a pipe that is plugged up with solder—it is a form of trouble that is too common.

Don't fill the radiator to overflow. When the water heats up it swells and a little "expansion" room is desirable.

Don't scoop dirty waer from a pool to use in the radiator. Scale, when it forms, is extremely difficult to remove.

Don't tolerate leaky joints in the cooling system. There is nothing that is more unsightly. The water has to be replaced and the chances of trouble from incrustation are very materially increased when the water has to be renewed frequently.

Don't let the hose connections of the water piping become sloppy. Just as soon as they show that they have done all the good work that may be expected of them, replace them with new sections; the cost is but a trifle—this plan will save a bad half-hour on the road some dark night when it is raining.

Don't follow up a street car on a rainy day. Traction is not then as good as it ought to be, and if the car comes to a sudden stop your automobile is likely to "enjoy" a rear-end collision.

Don't tread the car tracks if it can be avoided; the rails are usually frayed out in places, and the knife-edges are likely to cut the tread on the tire casing.

Don't neglect the air valves of the tires. The "sneaking" leak that follows neglect of this character is at great cost. Tires that are not kept properly inflated soon give out.

Don't fail to examine the rear axle and note if the bob-stays are held firmly in the saddles provided for them. Sometimes the stays jump out of the saddles and unless they are promptly replaced the axles will sag due to lack of support.

Don't neglect to examine the front axle and wheels at frequent intervals. If the wheels are not in good alignment the chances of steering trouble will be very great. It is even a good idea to so set the front wheels that they will toe in slightly; at any rate they should not toe out.

Don't fail to take up the slack of the side-chains as often as may be required; in performing this operation be sure and maintain the alignment of the rear axle.

Don't try to run the side-chains too tight; they should be given about one-half a link length of slack.

Don't neglect to keep the side-chains well lubricated. Lubricant protects the joints from the abrasive influence of sand and other road-side accumulations.

Don't be careless when washing the car; water may find its way into the carbureter; the ball bearings in the road wheels may also be given a water bath—what they need is oil, not water.

ANSWERS TO INQUIRIES WHICH WILL THROW SOME LIGHT ON THE RELATIVE MERITS OF RIGHT- AND LEFT-HAND STEERING; POWER CONSUMPTION OF ELECTRIC VEHICLES; THE BEST METHOD OF NEGOTIATING "THANK-YE-MA'AMS," SWEATING OF CARBURETERS, ETC.

Both Cylinders Do Not Act Alike

Editor THE AUTOMOBILE:

[2,336]—I am very much interested in your valuable journal, and particularly like the two pages devoted to letters and queries from your readers. I have been driving a bus for two summers and never before noticed that the exhaust from cylinder No. 1 sounded louder than that of the rear (the engine being of the 2-cylinder opposed type). Will you kindly tell me what could cause such a thing?

Quogue, N. Y. JOSEPH P. PAYNE.

The probabilities are that the rear cylinder is more or less flooded with lubricating oil. If the lubrication is all right, then the compression in the rear cylinder is not the same as that in the front. When both cylinders are working equally well from the point of view of compression and lubrication the trouble you complain of will disappear.

Autoist Relates an Unfortunate Experience

Editor THE AUTOMOBILE:

[2 337]—A few days since I crushed a Hyatt bearing on my driving shaft in such a way as to completely lock the rear system. The question which puzzled me was how to be towed to the nearest garage. My axletrees are provided with feather keys, for the purpose of fixation of the wheels to the same; these I removed after taking off the rear wheels, when we had no difficulty in being towed the same as any ordinary wagon. Any one having similar experience will do well to bear this item in mind, providing their car is similarly constructed. We had some trouble with the left-hand nut running off, so removed it entirely and fitted several leather washers to the spindle, or axletree, fastening them on with an improvised linch pin made of a common nail inserted in cotter pin hole. Any port in a storm must be the motto with an automobilist.

Troy, N. Y. J. H. BISSELL.

Autoist Wants to Know About Several Things

Editor THE AUTOMOBILE:

[2,338]—Please answer the following questions in your "Letters Interesting, Answered and Discussed" column:

1. What is the proper way to line up the wheels on an automobile so as to be sure they are in perfect alignment? I saw this answered about a year ago in THE AUTOMOBILE.

2. I have a car which is equipped with a non-vibrating coil; why is it that it will not start on the spark?

3. Why do I always have to whirl the engine to get it started, excepting after it is warmed up good and I make only a short stop, then it often starts on the quarter turn?

4. Quite often as I change gears from intermediate to high, as I let the clutch in (however easy), there is a fairly strong click as if there was lost motion somewhere. This is a new machine and did not do this until lately.

5. A friend of mine has a Remy magneto on his car and with all the spark advance he can give it, on either magneto or battery, it affects the speed of the engine but very little. Will be glad to see the above questions answered in THE AUTOMOBILE.

Minerva, Ohio. C. STOCKMAN.

1. The front wheels should toe in, each an equal amount, say, one-half of 1 degree. When the front wheels do toe in, skidding is less likely to occur, and steering is much easier and more certain. The amount of this toeing should not be enough to bring on acute tire trouble, nor will it, unless both wheels toe in very perceptibly. If the wheels do not toe in at all, skidding from other causes will be more damaging to tires than in the case of the toeing wheels, and the chances of damage from skidding will be far greater. A simple way to ascertain if the wheels are parallel is to measure the distance from felloe to felloe at the front and back of both the front and rear wheels. When the distance between felloe faces are the same at the front as at the rear the wheels are necessarily parallel. When fixing the distances for the front wheels, if it is desired to have them toe in, then the measurement between the faces of the felloes at the front of the axle should be slightly less than the measurement between the faces at the rear of the axle. There are, of course, other ways of arriving at parallelism of the wheels, but they are no more certain, having the disadvantage, moreover, of increasing the chances of error because the number of operations is increased.

2. The reason why your non-vibrating coil will not permit you to start on the spark is because you have no means available to produce the spark with the coil as described.

3. It is not unusual to have difficulty in starting a motor when it is cold, in which event it is necessary to spin the crank. A good ignition system is a long step in the right direction. Strong batteries will also help you out.

4. The click may be due to lack of clearance of some of the parts. Examine the mechanism closely and see if there is not a rubbing spot somewhere. If the click is due to lost motion, as an ill-fitting key, you will have serious trouble to cope with soon. The wise plan is to go to work.

5. This question cannot be answered with certainty because the information afforded is insufficient. By way of a remedy it will be necessary (a) to provide a battery that is in good working order, and that will deliver at least 6 volts on closed circuit; (b) good spark plugs must be utilized. Beyond the points as above stated it will be desirable to see that the compression is high enough in each of the cylinders, and it will be also necessary to look after the timing of the motor. When all these matters are properly cared for it will be time to suspect the magneto if the results are not satisfactory.

Largely a Matter of Personal Taste

Editor THE AUTOMOBILE:

[2,339]—Please advise me regarding the advantages in placing the steering wheel on the left or right-hand side of a motor.

Detroit, Mich. J. H. T.

It is something of an advantage in fore-door types of torpedo bodies, and for that matter with all touring cars, to be able to enter the front seat from both sides. If the steering wheel is on the left side, the side levers will come in the middle of the car and access may then be had to the right seat as freely as to the left. This advantage is entirely wiped out under ordinary conditions, due to the fact that spare tires are placed opposite the right entrance. The question as to whether or not a driver can do better work if he sits on the left-hand side of the car depends upon his previous practice. If he has overcome the difficulties involved in right-hand steering, there is nothing more to be said.

Worm Gear Is There for Purposes of Adjustment

Editor THE AUTOMOBILE:

[2,340]—In the July 7 issue of THE AUTOMOBILE there is a cut of the Owen differential. Is the little worm gear shown for adjusting the bearings? If not, what is its utility?

Allegheny, Pa. M. F.

Data of the Tests Must Be Examined

Editor THE AUTOMOBILE:

[2,341]—I am in receipt of a circular dealing with the power consumption of electric vehicles. In this circular they endeavor to make comparisons between different vehicles and they work out an expression for efficiency which takes the following form: "It takes 96 watts per carriage mile for a vehicle with two people on fair macadam. If a heavier battery is put in, it requires 123 watts per carriage mile." The conclusion is therefore drawn that the second vehicle is less efficient than the first. Inasmuch as the velocity of the two vehicles is not mentioned in any way, I fail to understand how these figures are in any way a legitimate comparison, and, as a subscriber to your valued publication, I would greatly appreciate an explanation from you which would clear my comprehension of this matter.

Denver, Col. K.

It is not possible to either refute or approve a test, if only the results are stated, and the data of the test is ignored. All that is claimed might be true, and yet the value of the statement would have to be measured in the light of the detailed facts.

Wants to Know How to Mix Picric Acid in Fuel

Editor THE AUTOMOBILE:

[2,342]—In THE AUTOMOBILE issued under date of July 21 I noticed an article written by James S. Madison on the subject "Enriching of Automobile Fuel," in which he states picric acid is most frequently used. I have heard that picric acid and sal ammoniac were good for this purpose. I would be pleased to have you state how much picric acid should be added to five gallons of gasoline to give good results.

Rossville, Ind. O. A. B.

Looks Like Interference on Neutral

Editor THE AUTOMOBILE:

[2,343]—I would like you to give me some information through your paper regarding a "kink" in my motor which I am unable to locate. The clutch and brake are both worked by one foot pedal, and in going down hills, when I throw out the clutch the motor will stop, and when I let the clutch in just before reaching the bottom of the hill the motor will start up again and works good on the level and in going up hills. The motor also frequently stops when I throw out the clutch and set the brake in bringing the car to a stop. Any information you can give me as to the reason for this will be appreciated.

Florence, Wis. F. B. WOLF.

When you throw out the clutch you evidently throw in something else. We should think that the neutral point is insufficient. Address a communication to the company stating clearly the nature of your trouble.

Some Drivers Use the Motor for Braking

Editor THE AUTOMOBILE:

[2,344]—While descending long grades it is the practice of some drivers to engage the intermediate gear and close the throttle. When they approach a waterbreak and wish to further retard the car's motion they use the foot brake momentarily without releasing the clutch. Is this practice detrimental to the motor or transmission? The waterbreaks of Western Pennsylvania can be crossed with less discomfort to the passengers if taken diagonally as shown at A, but it is easier on the car than to cross them head-on as shown at B (see illustration).

Allegheny, Pa. MURRY FAHNESTOCK.

There seems to be no objection to coasting down hill with the motor engaged and a low gear thrown in, provided the hill is not so steep as to make the motor race. In the latter event, it would be desirable to assist the motor by applying the brakes sufficiently for the purpose. It is not believed there is any objection to this practice.

Carbureter Sweating and How to Remedy It

Editor THE AUTOMOBILE:

[2,345]—Could you tell me through "Letters" in THE AUTOMOBILE the reason for the sweating of a carbureter on an air-cooled car when the carbureter is placed in front of the motor, having two cylinders? I would also like you to suggest a remedy.

Woodmere, L. I. LOSS OF POWER.

Sweating is caused when the gasoline is vaporized, due to refrigerating effect. Every liquid, when it is changed from its liquid state to a gas form, absorbs heat from its surroundings and the temperature of the surroundings is lowered. The amount of this refrigerating effect depends upon the characteristics of the liquid employed. Gasoline, for illustration, does not refrigerate nearly as much as anhydrous ammonia. The mere fact that the carbureter exterior and perhaps the intake manifold frosts up is a sign that a considerable amount of gasoline is being vaporized, perhaps too much. It might be well to readjust the carbureter with a view to starving the mixture with the hope perhaps that there will be less frosting and that the mixture will prove to be more efficiacious for its purpose. The fact that there is no frosting must not be taken as an absolute sign of good working conditions, because if the liquid goes into the combustion chamber before it vaporizes it will then "crack," forming a carbon deposit over the internal surfaces and arouse trouble in consequence.

Loss of power is due to so many things that it will be impossible to put your finger upon the precise trouble without going to some pains, more or less systematically. It is to be hoped that the compression in your cylinders is good, that the carburetion is satisfactory, and that the ignition system is capable and well timed. With all these matters properly attended to, it remains for your air-cooled motor to work at a sufficiently low temperature to permit of a sufficient weight of mixture to enter the cylinders and perform useful work. If your trouble is due to overheating, loss of power may then be charged to one or more wrong conditions, as pistons that stick when they are heated, due to expansion, poor lubrication, due to the burning up of the lubricating oil, and insufficient mixture, due to the fact that the incoming mixture is rarefied by heat, and this condition may be accentuated sufficiently to result in a noticeable loss of power.

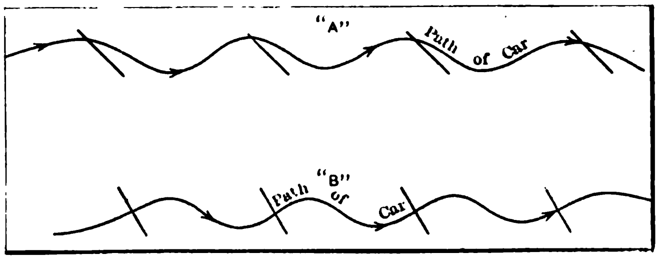
Depends Upon the Efficiency of the Steam Engine

Editor THE AUTOMOBILE:

[2,346]—I would like to know through your "Letters Interesting, Answered and Discussed" how many steam horsepower an automobile gasoline engine of 20 horsepower represents.

Quebec, Canada. KANUCK.

If the steam engine has a mechanical efficiency of 80 per cent. it will have to deliver 25 horsepower (indicated) in order to make the same actual delivery as that of a 20-horsepower gasoline motor. If the steam engine delivers 20 indicated horsepower it will deliver four less than a gasoline motor, or 16 horsepower. There is no difference between an actual horsepower delivered by a steam or a gasoline engine. In a steam engine the indicator does not measure the delivered horsepower; it does measure the indicated horsepower from which the mechanical losses must be taken. In a gasoline motor the delivered horsepower is measured on a dynamometer, hence the mechanical losses do not have to be taken into account to arrive at the actual delivered power.



How to take a waterbreak—A, easy on the passengers, but hard on the car; B, vice versa

Questions That Arise

FORMULAE SHOWING PROPER PROPORTIONS OF KEYS FOR SHAFTS; WHY ALUMINUM DOES NOT SOLDER READILY; SALT BATHS AND THEIR COMPOSITION

[211]—Is it not true that the proportions of keys for shafts are oftentimes wrong in that the shaft or the key is out of harmony on the assumption that the weakest link in any chain is the strongest? Why should the key be stronger than the shaft, or vice versa? What is the good of using two keys if one will do the work?

The shaft should be large enough in diameter so that when the keyway is cut the strength of the shaft should be equal to the ability of the key and the combination of the two should be equal to the work to be done with an ample factor of safety to assure that the service demanded will be rendered continuously. The formulæ as follows are intended to aid the designer to accomplish the undertaking. Let,

D = diameter of the shaft in inches;
B = breadth of the key and way in inches;
L = length of the key in inches;
T = twisting moment to be restrained in inch-pounds;
S_1 = Extreme fiber strain in the shaft due to the torsional moment;
S_2 = Extreme fiber strain in the key due to the torsional moment;

When,

$$T = \frac{\pi D^3 S_1}{16}$$

If the key is $\frac{D}{2}$ from the center of moments, then, for the key, we have:

$$T = \frac{\pi D^3 S_1}{16} = \frac{DLS_2D}{2}$$

$$\pi D^2 S_1 = 8BLS_2$$

and,

$$L = \frac{\pi D^2 S_1}{8BS}$$

[212]—Why is it that aluminum may not be soldered quite as readily as copper or other metals?

The aluminum alloys used in castings for automobile work, while they differ as to composition to a considerable extent, hold from 90 to 92 per cent. aluminum, the balance being copper, manganese, a trace of iron, etc. In attempting to solder aluminum, the first difficulty encountered is due to its low melting point. With copper it is possible to tin the surfaces when they will remain in good condition, and may be soldered by the mere application of a sufficient amount of heat at the right temperature, with no danger of damaging the copper by overheating, nor is there any tendency to oxidation. Aluminum, on the other hand, can scarcely be cleaned sufficiently to permit of "tinning," due to the fact that oxides form so rapidly that they interfere with the tinning process even though the work be done speedily. In order to solder aluminum it is necessary to heat the parts to be joined up to the melting point of solder, and after the surfaces are freed of moisture they must be cleaned by scratching with a metal brush, after which, if a suitable grade of solder is allowed to melt and run over the newly scratched surfaces, using the brush to bring about intimate contact, the solder will adhere to the surfaces, thus completing the tinning process. The solder must be made up of zinc (predominating), some tin and a small proportion of aluminum. The best way to proceed is to first bring about a condition of tinning as above indicated, using the solder high in zinc, and when the surfaces are tinned over join them together before they are allowed to cool off, thus preventing the formation of any oxide.

[213]—It is frequently stated that in quenching steel the results will vary depending upon the quenching baths, and that some baths are much more efficacious than others. What is the range of values of the respective baths?

The bath to use depends upon the results desired, and the efficacy of the respective baths may be taken as follows:

(A) Mercury.
(B) Acidulated water (ice cold).
(C) Salt water (ice cold).
(D) Salt water (normal temperature).
(E) Potable water (normal temperature).
(F) Water and skim milk.
(G) Lime water.
(H) Fish oil.
(I) Cod liver oil.
(J) Cotton seed oil.

It will be understood that mercury is too poisonous a material to utilize as a quenching bath for anything but very small pieces; even then the artisan must exercise great care. With mercury the parts to be quenched will be rendered the most hard. In the scale of hardness acidulated water comes next, then salt water, and so on down the line, finally reaching cotton seed oil which has the least ability of all the baths given from the purely hardness point of view. The oil baths, however, impart tough-hard qualities, which are frequently much to be desired as compared with the more brittle hardness due to water quenching. Sometimes it is found desirable to double quench, that is to say, quench first in oil and second in water, or have a surface of oil on the water so that the parts in being quenched contact with oil first, and finally drop into the water.

[214]—What is the particular advantage of salt heat treatment baths as compared with muffled furnaces and the open hearth? What salts are used in this class of work?

Despite the excellent control which may be had over gas furnaces, the fact remains that the temperature is not absolutely uniform at all points, and the parts to be heat treated are only uniformly heated when an expert handles the furnace. Open-hearth work is of course much more irregular than that following the use of a muffled furnace. Salt baths have the virtue of being uniform in temperature throughout, and the parts to be heated are of course raised to the temperature of the bath. The great advantage of the salt bath then lies in the perfect uniformity of the maintained temperature, and the results should be more perfect, due to this fact. The composition of the salts used in heat treatment work depends upon the temperature desired, the following being some of the mixtures that are found to be efficacious for the purpose:

SALT BATH FOR WORK UP TO 1,000 DEGREES CENTIGRADE

	Per cent.
$NaOH$, Sodium Hydrate	8
$NaCl$, Sodium Chloride (common salt)	91
KNO_3, Potassium Nitrate	0.5
K_2CrO_4, Potassium Chromate	0.5

The above compound of the available salts is designed for use at temperatures ranging between 800 and 1,000 degrees centigrade, and for lower temperatures it is possible to employ other compositions, as chloride of barium and chloride of potassium in the ratio of 3 to 2, if the maximum temperature is not to exceed 950 degrees centigrade. The low limit of this compound is 670 degrees, which is the temperature of melting of the same. The 1,000 degrees bath is more nearly universal than that of barium and potassium chlorides. By varying the proportions of the mixtures, other temperatures may be introduced. In working these salts it is necessary to employ an electric crucible.

The Pyrometer

ITS DEVELOPMENT AND USE. BEING THE FINAL INSTALLMENT OF AN ARTICLE BY WM. H. BRISTOL READ BEFORE THE SOCIETY OF AUTOMOBILE ENGINEERS AT ITS SUMMER MEETING

A PIECE of steel which is to be tested is made in cylindrical form, about 7-16 inch in diameter and 1 1-4 inches long, with a hole drilled in the end to receive the tip of the thermo couple. A vessel of water is provided for maintaining the cold end of the couple at the desired temperature. The quartz-lined furnace allows it to be brought to a high heat very promptly, and after the sample has been inserted the complete heating curve showing the absorption point will be recorded on the chart within a few minutes, after which the cooling curve can be also obtained by lifting the small sample out of the furnace and allowing it to cool.

The recording instrument is provided with a mechanical half-second vibrator so that the continuous record is made on the chart as the temperature rises and falls, even though the changes are quite rapid.

The fire end used in connection with this apparatus is made from exactly the same material as the couple which is used in the treatment of the steel from which the sample is taken, and, therefore, the practical results desired are made to depend upon the preliminary tests.

A special form of thermo-electric couple has been designed for quickly taking the temperature of molten metal. It consists of two elements of different alloys which are left disconnected at the end where the junction is usually made.

In Fig. 18 one of these couples and a portable instrument is shown, with a cross-section of the couple. One element of the couple is a tube, the other a special alloy wire with insulation between the wire and tube. When this couple is immersed in a crucible of molten metal, electric connection is made between the outside tube and the insulated wire at the end of the tube, and a reading will be obtained of the temperature of the molten metal at the tip of the thermo-electric couple.

This form of couple has been successfully used for taking the temperature of molten metals while crucibles are in the furnace.

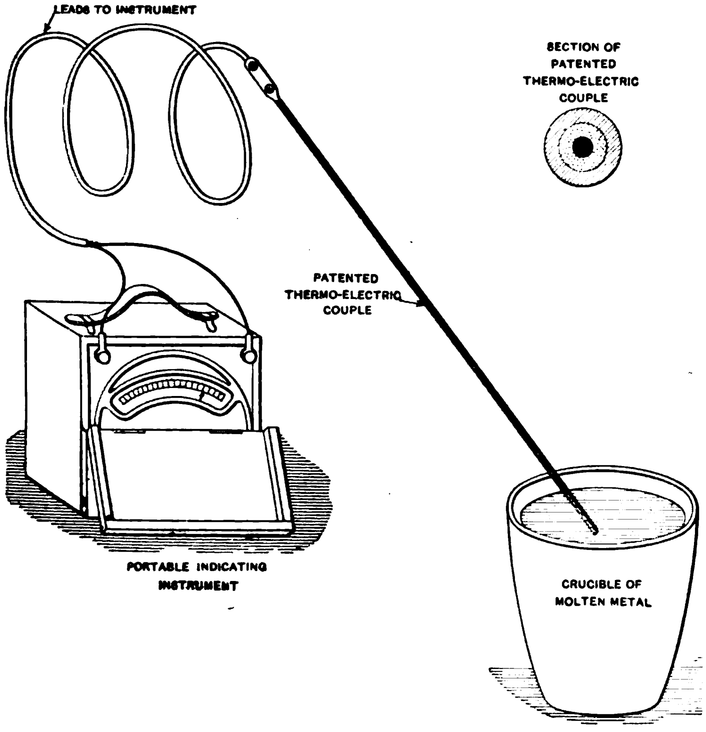


Fig. 18—Portable thermo-electric couple for taking temperature of molten metals

In the use of pyrometers for every-day shop practice, methods of checking the accuracy of the instruments are important.

The initial cost of spare fire ends is so low that extra fire ends should always be kept on hand. To be sure that the fire end which has been in service is accurate, a new one may temporarily be connected to the leads of instrument, both fire ends being placed side by side in the furnace or bath of molten metal during the test. To check the instruments an auxiliary portable pyrometer is recommended having its own set of leads and extension piece. Then the portable instrument may be connected to the fire end in service in place of the regular instrument, thus furnishing a ready means of determining its accuracy.

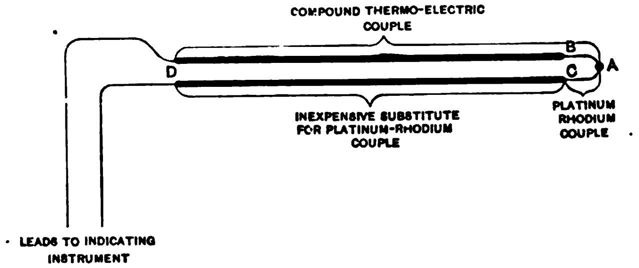

Fig. 19—Diagram showing construction of compound thermo-electric couple

The fusion points of metals also afford convenient means of checking pyrometers. Le Chatelier platinum, platinum-rhodium couples with suspension-type galvanometers are recommended for laboratory tests and for calibration.

For quick measurement of furnaces having temperatures between 2,000 and 3,000° Fahr. a modified form of the standard platinum, platinum-rhodium couple has been developed which has proved valuable in practice.

The diagram Fig. 19 illustrates the construction of the compound couple as it is called. Special alloy base metals having cross section several times greater than the platinum elements are joined to the platinum and platinum-rhodium elements at A and B, the special alloys used being selected so that the thermo-electric effects of the juncture at A and B balance each other, and the reading on the instrument depending entirely upon the thermo-electric current produced by the junction C. The secondary junction should not be heated above 1,200° F.

The cross-section of the special alloy extensions of the platinum, platinum-rhodium couple are made of sufficient size so that the resistance will not appreciably affect the accuracy of the readings on instrument, even if made of considerable length. The tip of the platinum-rhodium couple is left exposed for about one-half inch, the remainder of the couple being inclosed in an iron protecting tube. An extra guard tube or sheath is provided with a set screw to cover the delicate platinum tip for transportation, and while inserting and while drawing fire end from furnace.

Readings of the flame temperatures of a furnace may be made with the instrument within a few seconds.

Steel Must Be Selected in View of the Duty

It is too frequently claimed that by a mere process of heat-treatment it is possible to obtain the most desirable results without selecting the grades of steel that are suited to the place and the character of the work to be done. That this is a fallacy is well appreciated by those who have studied the situation. Proper selection must not be neglected—heat-treatment is secondary.

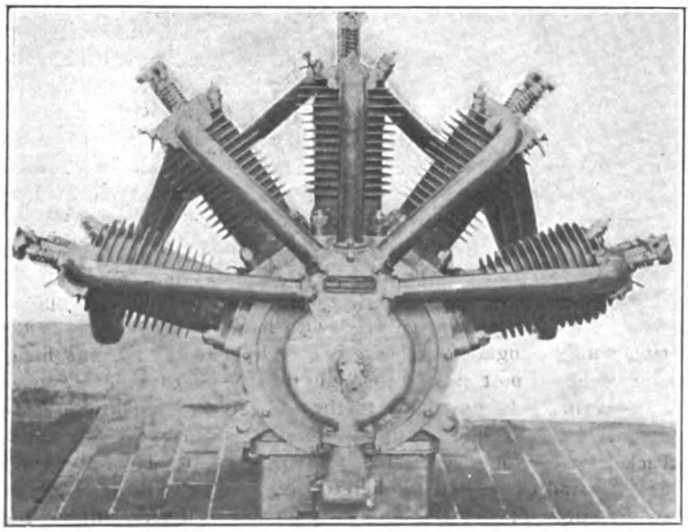
Digest

BRIEF RESUME FROM 50 FOREIGN PAPERS: GERMAN PRECAUTIONS AGAINST FIRE IN GARAGES—THE R. E. P. MOTOR—MAYBACH'S LUBRICATOR WITHOUT SPRINGS—SOME TELLING TESTS OF GNOME MOTOR

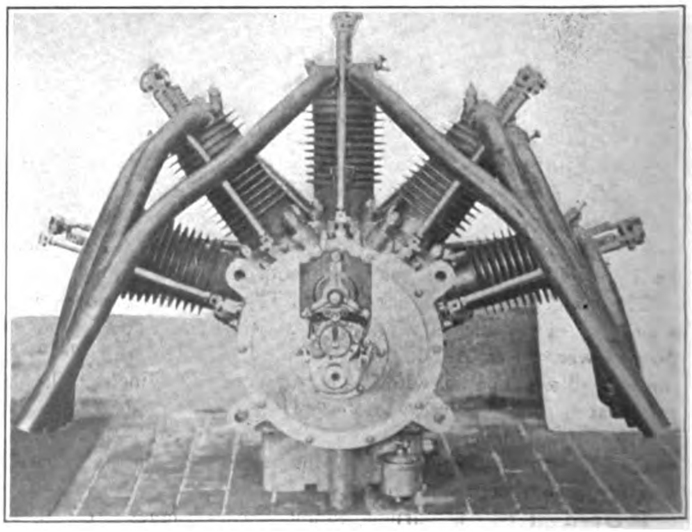
With a view to safety against fire in its garages the Berlin General Omnibus Company has for some time endeavored to develop an explosion-proof incandescent lamp plug which may be connected and disconnected by simple insertion and withdrawal (Westinghouse type). The regulations of the Association of German Electrotechnicians prescribed that no apparatus in which the breaking or making of electric contact is a normal function may be employed in any business place in which there may be danger of explosion, unless its construction has first been approved as explosion-proof. And the Omnibus Company had found that lamps suspended from movable wires to be connected up at any convenient place by insertion of a plug (not a screw plug, since this would twist the wire and the lamps suspended from it) were indispensable for the night work of cleaning, testing and repairing of automobiles regularly carried on in the company's large garages. Several plugs offered in the open trade were tried but were found either not safe enough to be approved or not substantial enough to withstand wear and tear. The connection shown in the accompanying illustration was then developed by the company's engineer, and its security consists of course in the double air space around the contact, the outer space remaining closed till the arc in the inner one disappears. It was tried officially in connection with an incandescent lamp in a box containing an explosive mixture of benzine, gas and air, and the capacity of this mixture for producing an explosion was tested at regular intervals during the test. The connecting and disconnecting was done mechanically, and after contact had been switched off and on 5370 times without causing an explosion the plug was examined and, while it showed wear at the push joint, its continued safety was considered satisfactory. The question arising whether the height of the switch above the floor of a work room did not in itself offer sufficient guarantee against explosions, on the ground of the higher specific gravity of benzine or gasoline vapor as compared with air, another test was arranged at which the underwriters and representatives of the fire department were present. Sixty liters of benzine of specific gravity 0.750 was poured out over the floor of a garage with 80 square meters of floor space and six meters height of ceiling, and all openings were closed, in so far as practicable. The temperature of the place was about 20° C. After about one-half hour, when nearly all the benzine had evaporated, samples of the air were taken at heights of 1-2, 2, 3 1-2 and 5 meters. Trials with an explosion tube failed to bring any of the samples to explosion. Quantitative analysis showed that the samples taken from the lowest stratum contained 0.9 volume-per cent. of benzine vapor. But according to Bünte a mixture of benzine vapor and air does not become explosible until the volume-per cent. of benzine vapor reaches 2.5, and ceases to be explosible when it reaches 4.8. On the basis of these trials a permit was granted to the Omnibus Company to make use of the construction here shown, provided the plugs were placed at least 1 1-2 meters above the floor.—*Zeitschrift des Mitteleuropaischen Motorwagen Vereins, ultimo* July.

Among the aviation motors whose type promises a wider application, the R. E. P., called after its designer, the young aviator-engineer-builder Robert Esnault-Pelterie, attracts attention. It develops 50 to 60 hp. with five cylinders 110 by 120 which work on a single crankpin similarly as the Italian Miller motor, one of the connecting-rods embracing the pin with a hard bronze bushing and the others working upon the knuckle of the first one, by which arrangement the piston travel is not quite alike for the five cylinders. The ignition takes place in two cylinders in the order, 2, 4, 1, 3, 5. A single valve cam disk rotated at one-fourth the speed of the crankshaft takes care of the valve movements by means of a plurality of cam formations on its grooved periphery. Each cylinder carries on its hemispherical combustion chamber two valves operated by a rocker arm controlled by tappet from the aforesaid cam disk. The intermediate shaft for the gear driving the latter drives the magneto direct, having a speed suitable for this purpose. Lubricating oil is carried to the crankpin and other connecting-rod bearings through the hollow crankshaft. The double disposal of the exhaust is shown plainly in the accompanying rear view of the motor. The carbureter has a special air intake controlled in connection with the throttle, and this intake is sheltered from sudden atmospheric variations. A five-day trial from June 16 to 21 in the testing department of the Automobile Club of France showed a consumption of fuel of 270 grammes per horsepower hour. The weight of the motor with magneto, carbureter and storage battery for auxiliary ignition amounts to 150 kilos.—*La Vie au Grand Air.*

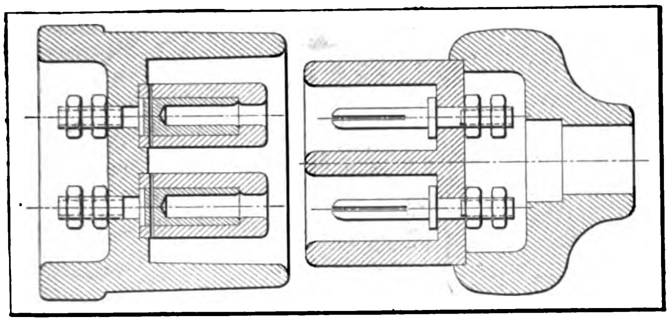
In a multiple lubricator patented by Maybach (German Daimler) visible feed, independence of temperatures and adjustability for each oil lead are features secured in a very com-



Front view of the R. E. P. aviation motor

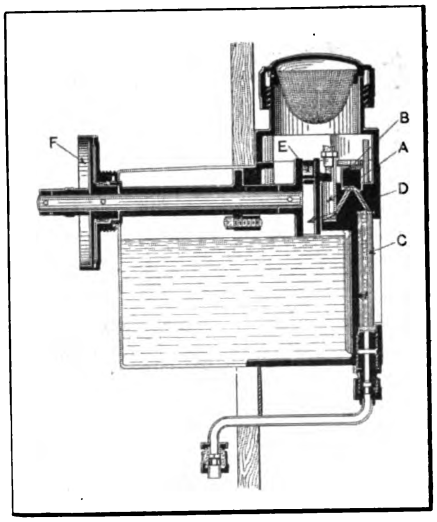


Rear view of the R. E. P. aviation motor



German safety lamp connection for garages

pact construction dispensing with springs, valves and fittings. The visibility of the feed is obtained by having the pumps for each individual oil lead send measured air bubbles alternately with oil through the glass sights. To insure equal feed, whether the oil is cold or warm, thick or thin, the distribution of oil and air from the reservoir to the pumps and from the pumps to the leads is effected by means of a sliding plate which effectively interrupts all communication between suction and pressure conduits, so that no oil can run back during either the suction stroke or the pressure stroke. In the illustration *A* represents the individual pumps, *B* the distribution slide, *C* the sights, *D* the actuating bar or ruler, *E* the driving crank and *F* the external driving pulley. The slide is shown in the position which produces a connection between pump and lead. Accordingly as it is moved, the oil and air suction conduits are alternately connected with the pumps. The bar *D* is moved to and fro by the crank *E* and at the same time up and down by means of a cam. The to-and-fro movement actuates the slide and the up-and-down movement the pumps. By a gear in the ratio of 1 to 12, taking the place of pulley *F*, the oiler may be driven from the camshaft and by variations in this ratio the general feed may be increased or reduced. To give the individual leads less oil, the adjustment nuts on each piston may be turned back, imparting a corresponding amount of lost motion to the piston.—*Zeitschrift d. Mittel. Motorwagen Vereins.*



New Maybach patent force-feed oiler

At a half-hour test of the revolving 14-cylinder Gnome motor weighing 138 kilos and rated at 100 hp. the consumption of gasoline at 1 000 r.p.m. was 5.7 kilos and of lubricating oil 4.4 kilos, hp. 76.1 and at a one-hour test at 1,100 r.p.m., 22.7 kilos gasoline and 11 kilos oil, hp. 74.4—*Bulletin Officiel.*

Lozier Announcement

THIS WELL-KNOWN MAKE OF CAR IS OFFERED FOR 1911 SUBJECT TO SUCH REFINEMENTS AS ANOTHER YEAR'S EXPERIENCE DICTATES

FOR the season of 1911 the Lozier Motor Company, of Plattsburg, N. Y., and Detroit, Mich., still retains its slogan of "The highest grade and quality of motor car possible to produce, and regardless of expense." The company will devote its energies during the coming twelvemonth to the production of two high-class cars—Types 46 and 51, high-powered four and six-cylinder models respectively. With these two chassis eight different varieties of body equipment will be furnished—Touring, Briarcliff, Lakewood and Limousine for each of the two models. The seven-passenger touring car will be practically the same as last season, except that it will be fitted with fore-doors. The Lakewood, which, by the way, was the first American stock car built with fore-doors, is a decided improvement over last year in that it has a side door which folds downward and outward, disclosing a chauffeur's seat, this affording accommodations for five passengers. There will be no change in the Briarcliff body from the 1910 lines. It is to be remembered that any style of body which can be fitted to a four-cylinder car is also applicable to the six-cylinder chassis, there being no difference in the chassis construction aside from the motor. The touring and limousine bodies in both models accommodate seven passengers; the Briarcliff and Lakewood bodies seat five.

The six-cylinder chassis, known as Type 51, has cylinders with a bore of 4 5-8 inches with a 5 1-2-inch stroke, developing 51 horsepower, A. L. A. M. rating. The four-cylinder model, denominated as Type 46, with 5 3-8-inch bore and 6-inch stroke, is rated at 46 horsepower A. L. A. M.

The six-cylinder chassis has a wheel-base length of 131 inches, that of the four-cylinder model being 124 inches; the tread on all Lozier models being 56 inches.

The weight of the various equipped cars ranges from 3,375 pounds for the Briarcliff and Lakewood fours to 4,375 pounds for the six-seated limousine.

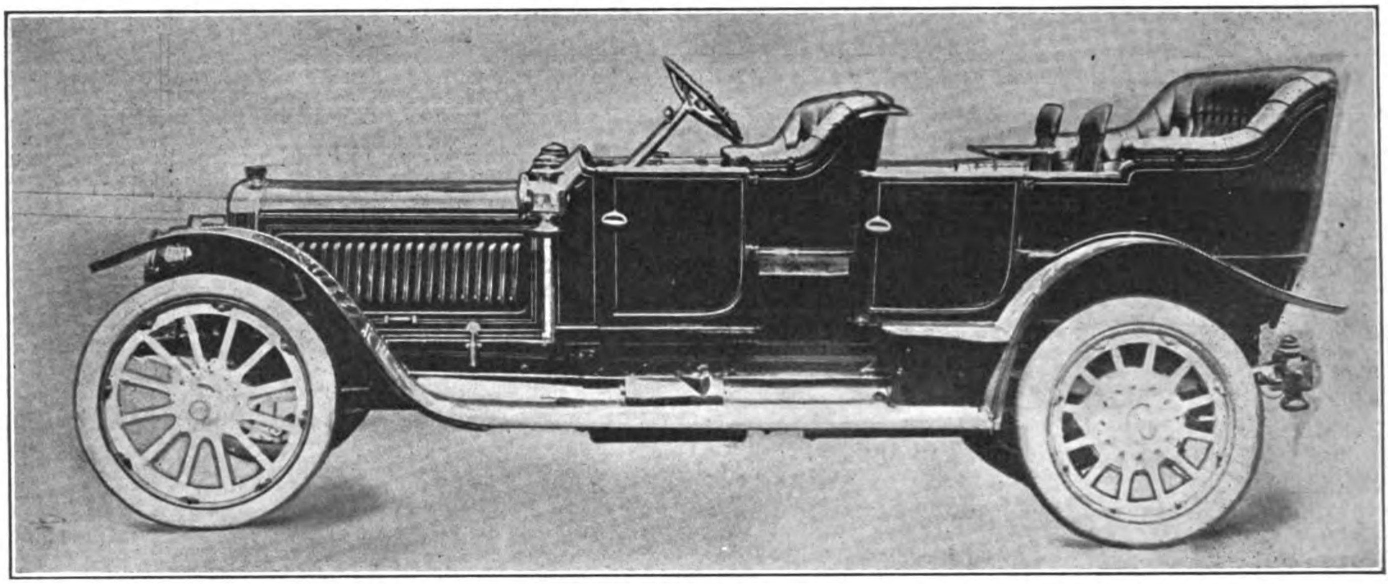
Four powerful brakes on the rear-wheel drums constitute the brake system. All movable or wearing parts of the brake system are fitted with grease cups. The emergency brake rings are of the floating type, perfectly equalizing in themselves; and in addition, brake-beam equalizers are fitted through slots in the frame. The adjustments of the braking system are worthy of note, the contracting bands being provided with winged nut adjusters, while in the emergency brake rod is inserted a turn buckle with hand-lever adjustment. Springs are of the half-elliptic front and platform rear type, all shackles being fitted with hollow pins, bronze bushed and fitted with grease cups.

Suspended under the rear of the chassis frame is the gasoline tank with a capacity of thirty gallons, and gasoline is supplied to the carbureter by an automatic pressure system. In the gasoline line is fitted a combination strainer and water separator, it being possible to remove the strainer for cleaning without removing any of the floor boards.

The frame is of alloy steel, heat treated in lead, with arched rear and extremely narrow front, giving short turning radius. The steering gear is irreversible, of the worm and toothed wheel type; and instead of using a sector the gear wheel which engages the worm forms a complete circle and new faces may be presented to the worm in case of wear.

The steering wheel consists of a cast aluminum rim, spokes and hub, the rim being covered with hard rubber, cast over the rim, with corrugations to give a firm hold to the driver's hand. The steering post passes through the toe-board in an annular ball-bearing, adding greatly to the easy steering qualities of the car. The cross link of the steering mechanism is positioned back of the front axle, while the drag link is above the front axle instead of below it as heretofore.

The entire underbody of the car is protected from injury and road drift by a continuous casing of cast aluminum alloy, and while the clutch is protected from road drift and dirt by being encased in a dust-proof metallic case, the cast-aluminum fly-



Six-cylinder 51-horsepower fore-door type Lozier touring car with a long hood, straight lines, wide entrances, and clean running-board

wheel pan assists in keeping the power plant clean and free from mud or dust.

Road wheels are 36 inches in diameter, the front being equipped with 4-inch tires, the rear with 5-inch tires. All models are regularly fitted with Continental demountable rims. The front wheels are now fitted with adjustable cup and cone ball-bearings instead of bearings of the annular type.

Notable Changes Made in the Cars

Perhaps the most notable change in motor construction lies in the adoption of the long stroke. The cylinders are cast in pairs, T-head type, and finished in pearl gray by an enameled process with a final baking. The water-piping, intake pipe, fan standards and other small parts are cast from aluminum and given a polish. The motor valves are of high nickel steel with integral heads, and it is worthy of note that the fillets at the joints of heads and stems are large, so that the heat picked up by the heads is quickly transmitted over the whole length and warping is prevented. The valves are larger in size than they were in last year's cars, and valve guides are inserted in the cylinders, making it possible to renew them should they become warm without having to renew the whole cylinder. The valve covers of both the models are screwed into the heads. The pistons and rings are given a final grinding and are brought to gauge. The reciprocating parts are balanced. The hollow wrist pin is made of tool-steel and is prevented from floating out by two set screws near the ends, and they in turn are prevented from backing out by a wire lock between the heads of the two screws. As in former years, the crankshaft is mounted on annular type ball bearings; even the camshafts rotate on ball bearings of the annular type, and this type of bearing is extended to include the rotative parts of the magneto, pump shaft, fan, clutch, leaving no bearings to the tender mercies of chance or the exigencies of hard service.

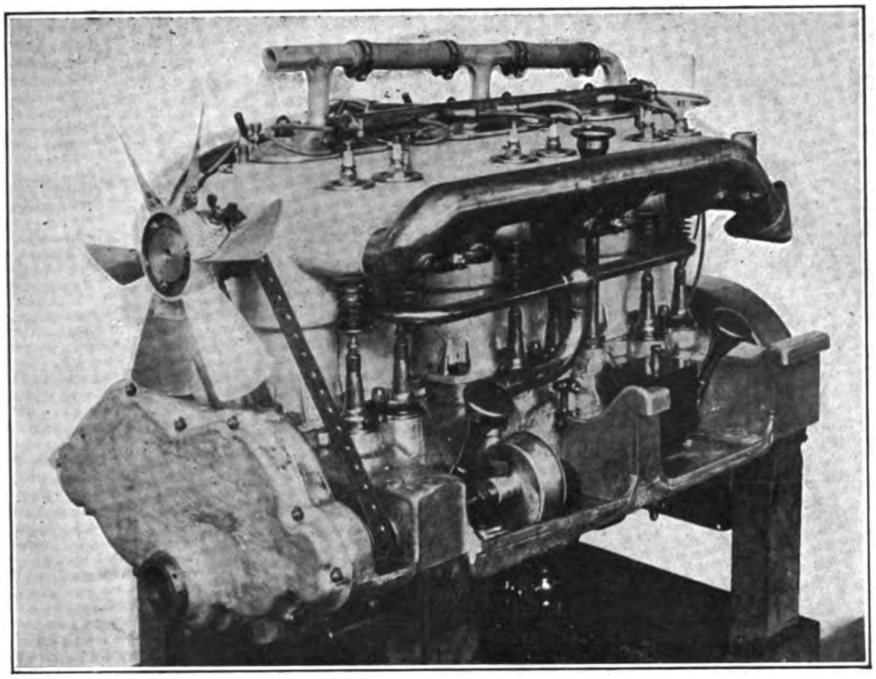
Right side of the Lozier six-cylinder 51-horsepower motor, presenting the Stromberg carbureter, magneto, and method of driving

The ignition system remains as before. It consists of two separate methods, including a Bosch high-tension magneto and a storage battery of large capacity, working in conjunction with a coil and distributor, with two independent sets of spark plugs.

Lubrication is by splash. A gear-driven pump supplies the oil to the motor, an auxiliary oil tank is placed on the chassis and a hand-pump is connected therewith through the good office of which lubricant may be supplied to the bearings needing it at the



Left side of Lozier "six" motor, showing water pump connections, and fan drive

will of the operator.

The clutch is of the multiple disc type, as in last year's car; it is made up of 31 steel discs in an oil-tight, dust-proof flywheel housing. The driving discs are mounted on annular ball bearings. A clutch retarding brake is utilized for the purpose of overcoming inertia, thus rendering the gear shifting operation simple and preventing disastrous clashing.

The transmission is of the 4-speed, selective sliding type, with an aluminum box in one piece, provided with a cover. This is a departure from the usual practice of halving the box, and it is claimed for this construction that oil leakage is eliminated. The direct drive is on third speed, as in former Lozier cars. The ratio is about 3 to 1, it being the idea that in autoing it is practicable to run on the third speed for most of the time. Using this speed direct assures a certain silence of performance and reduces the necessity of listening to the hum of gears nearly all the time.

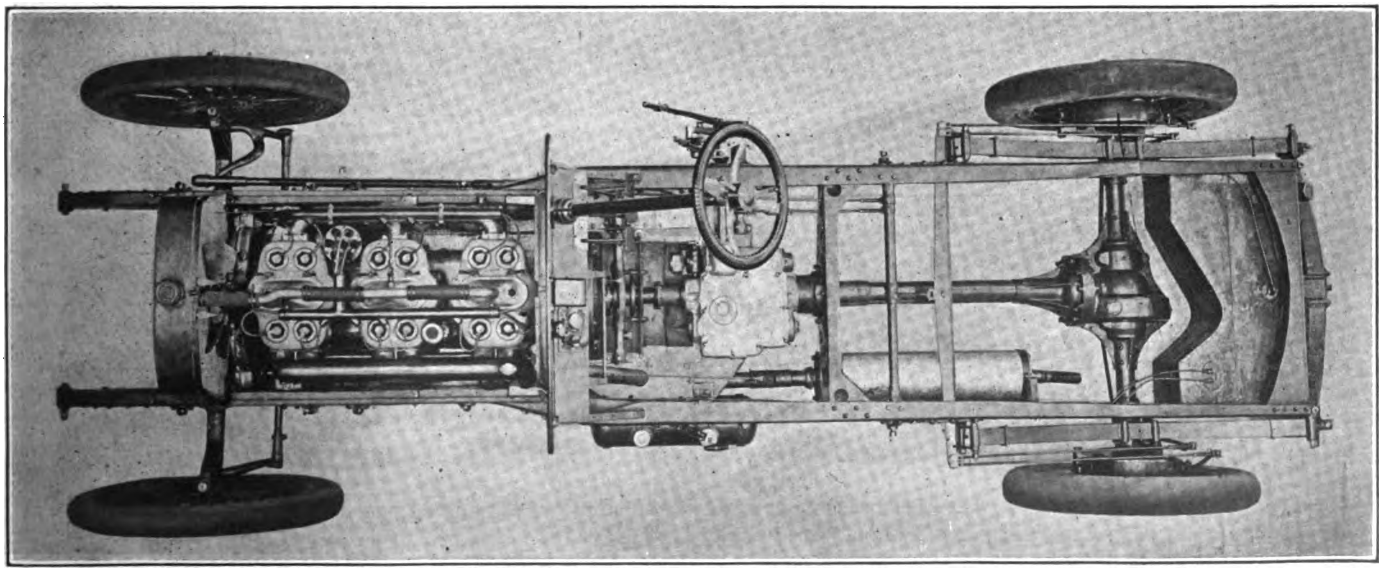
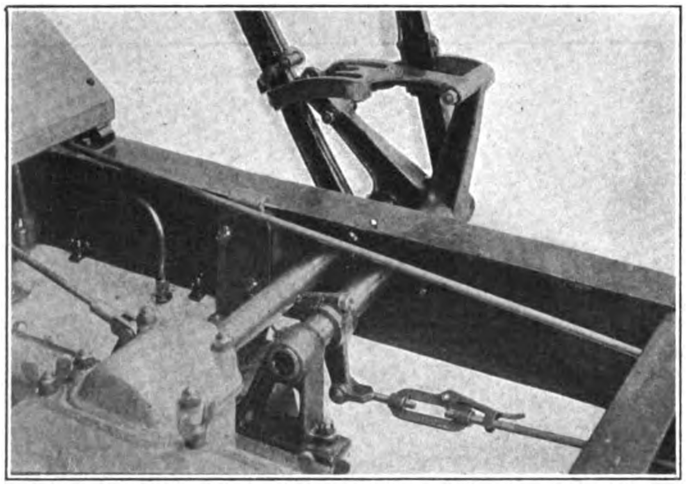
The final drive is by a cardan shaft of the full floating type without universal joints, although the forward end of the shaft terminates in a universally held member related to a substantial cross bar fastened in the two members of the chassis frame, there being a large ball-shaped housing with ample bearing surface to take the shock and do the work.

This construction eliminates the need of a torsion rod, the torsion function being performed by a tubular housing, of nickel steel, bolted rigidly to the differential case of the live rear axle with its extremity composed of a telescopic joint as before mentioned. The live axle is so designed as to be readily withdrawn, and by unbolting the two straps holding the differential in place the entire differential and main gear may be removed. Both of the main drive bevels are mounted on ball bearings, the drive shaft bevel being supported on the floating end by a ball bearing, as well as at the forward end, and both bevels are provided in addition with adjustable thrust bearings.

A change has been made in the radius rod, which, instead of terminating in ball and socket members, is designed to encircle the rear axle at the rear end, while the forward end terminates in a bronze bushed eye and is held by a pin of liberal dimensions. The radius rods are made from D-shaped drop forgings. The spring perches are free to turn on the rear axle tubes, it being the idea to induce flexibility, which quality is also added to through the good properties of the telescopic joint at the forward end of the propeller shaft housing.



Chassis plan of the six-cylinder 51-horsepower car indicating the relations of units and method employed for obtaining clearance for the gasoline tank in the rear



Part of the Lozier side-frame at the point of fastening of the quadrant for the side-levers

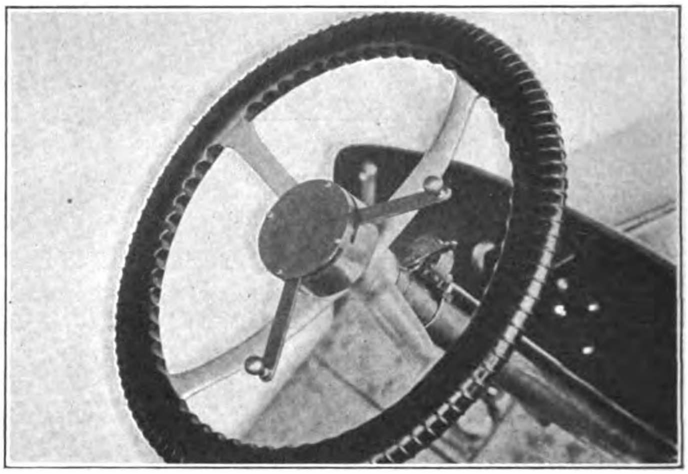
Among the improvements to be noted in the motor is a compression release on the exhaust valves. The starting-handle axle is enclosed in an oil-tight housing, excluding the entrance of dust, and when the handle is let go after starting the motor it is so contrived as to remain in the upright position, nor is there an external latch or strap employed. The magneto and carbureter are located on the right side of the motor, the latter being of the Stromberg type. The magneto is driven by an extension shaft out of the half-time gear housing, the pinion of which meshes with the train; the magneto is flexibly mounted, the universal joint for the same coming just back of the right fore arm of the motor case. The left side of the motor holds the water pump, makes room for a well contrived exhaust manifold, with the water piping just beneath, and the fan is driven by a belt which passes around a driving pulley, the latter being on a shaft which is driven by a pinion located relatively the same as the magneto drive. The motor is supported by three arms, and instead of an underpan, the aluminum case is flanged out between the arms and is faced to snug up against the underflange of the chassis frame.

An examination of the chassis will disclose a nice relation of the units with means for ready assembling, and among the other features of distinctly Lozier characteristics is the idea of the independent placing of the emergency brake mechanism so that the ills of torsion do not interfere with the sliding mechanism. The gasoline tank is placed back of the rear axle high up to afford the proper ground clearance, and it is so shaped that the differential housing clears, but the capacity of the tank is increased, due to the advantage taken by fixing a constant clearance line following the contour of the axle.

The regular Lozier equipment includes trunk rack, robe rail, foot rest, horn, brass tire-holders, tool box with complete set of tools, Prest-o-Lite tank, two gas headlights, dash lamps and tail lamp, the latter being a combination of oil and electric. The battery has extra large amperage calculated to furnish ample current for motor, lamps, Klaxon horn, speedometer, etc.

As to price, all the models of Type 51 are listed at $5,500, with the exception of the limousine, which is quoted at $7,000. The latter style in Type 46 is catalogued at $6,000, the other three styles at $4,600.

Upon the completion of the magnificent Lozier plant at Detroit no more complete cars will be built at the company's Plattsburg factory; that plant will thenceforth turn out castings, gears, machine screw parts and other supplies for the new works at Detroit. Two large additions have recently been put up at Plattsburg, and the plant there will continue to be operated to the fullest extent.



Lozier steering equipment, showing a large diameter fluted grip on the wheel, stout post, with secure anchorage at the foot-board

Ideal Electric Vehicle

MECHANICAL AND ELECTRICAL FEATURES OF THE IDEAL, SHOWING THE RELATIONS OF THE COMPONENT UNITS AND METHOD OF CONNECTING UP THE ELECTRICAL SYSTEM

LONG-continued effort in the electrical field of endeavor has brought most of the equipment down to a standard basis, but there is still a chance for the individual to exercise his ingenuity. The Ideal Electric Company, of Chicago, Ill., having in mind certain requirements for vehicles in this class, entered the field with the intention of supplying the obvious needs. The appearance of the car is shown in Fig. 1, which, in a general way, may be set down as a town car with inside control, side-chain drive, using an individual motor and a silent chain for the primary reduction. The chassis is so contrived that the battery is properly housed in two sections; one at the front, and the other at the back end, bringing the weight over the springs and so distributing it that the riding qualities of the car are very good. The center of gravity is low and the road performance notable.

The motor is shown in Fig. 2; it is of the Westinghouse vehicle type, fully enclosed, and is flexibly mounted upon the jackshaft J1, using bearings B1 and B2. The support to the side-frame S1 at one end has a liberally proportioned flange F1, and the silent-chain drive S2 is clearly shown at the point where the cover is removed from the housing for the same. The differential gear is in the same housing at the enlargement E1 and the point of fastening or flanging to the remaining side-frame comes at F2. The driving sprockets are pressed on the ends of the jackshafts at S3 and S4. The wiring for the motor is secured to suitable terminals at W1, and the arrangement is such that the wiring conforms to the diagram of the same as depicted in Fig. 3.

One of the Matters of Recognized Importance

In electric vehicle work it is almost impossible to keep acid fumes out of contact with the wiring system, and in order to avoid the resulting difficulties it was deemed expedient in this car to run the wiring system in such a way as to have it accessible for repair, but at the same time protected from acid fumes and mechanical interferences of every kind. The wiring is done according to the plan as shown in Fig. 3, and is so arranged as to include the connections to a battery divided into two parts, one of which is marked "front battery" and the remaining subdivision is designated as "rear battery." The controller is so designed as to include four forward speeds, the "off position" and reverse. In first speed a resistance is employed, and its relation to a field shunt is shown in the wiring diagram. The equipment includes a single motor, a voltmeter V and an ampere meter A, also a bell for signaling, and the lighting is done by means of electric lamps with connections to lamp circuit as indicated. The charging receptacle connects the two halves of the battery in series, including an ampere meter, with the understanding, of course, that the voltmeter is connected in parallel to show the voltage on charge and the voltage of the battery during discharge. Beyond commenting upon the correctness of the method employed in the connecting up of the equipment used, it is worth while taking into account the fact that the company has standardized its methods, so that the artisans when they become accustomed to the work are enabled to proceed with accuracy and dispatch, thus reducing the cost of repairs, and what is more to the point, the time a car will be out of commission, should repair work become a necessity.

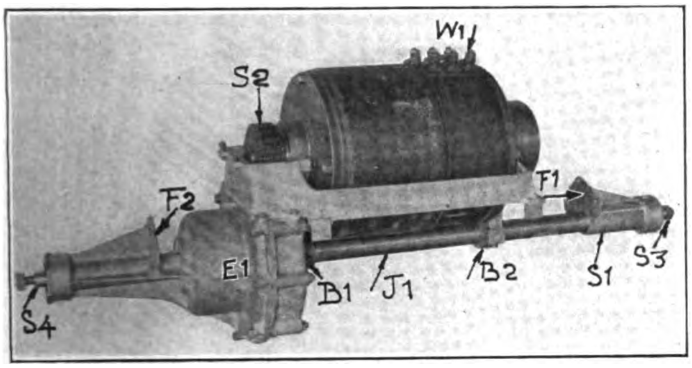


Fig. 2—Westinghouse motor with a double-reduction gear, the primary reduction being with a silent chain

Methods of Control Carefully Looked After

The fact that electric automobiles are to be driven a considerable portion of the time by those who may be entirely devoid of mechanical training renders it necessary to so contrive the control system that it will not prove to be too complex to be readily understood. In addition to the question of the number of speeds available, it still remains to so arrange them that they will respond logically and when the power is cut off the brakes should be readily applied if it is desired to do so. In this car the control lever is placed to the left of the driver, who also sits at the left side of the seat, and there are four forward speeds arranged progressively so that pushing the lever in the forward direction throws in the four forward speeds one after the other, and pulling the lever backward has the reverse effect. If, after the lever is shifted to the zero position, it is desired to apply the brakes, all that has to be done is to pull the lever back from neutral to perform this operation. If it is desired to go into reverse, however, the lever must be shifted sidewise for a short distance and then pulled back.

The steering equipment consists of a tiller within the car located on the left side convenient to the driver, and the mechanism it actuates is simple and strong. The connecting links are of adequate strength, placed in protected positions, and all the joints are so carefully made that lost motion is kept out. The axles are of the I-section, forged in one piece from suitable grades of steel, and the remaining details are worked out in a fitting manner.

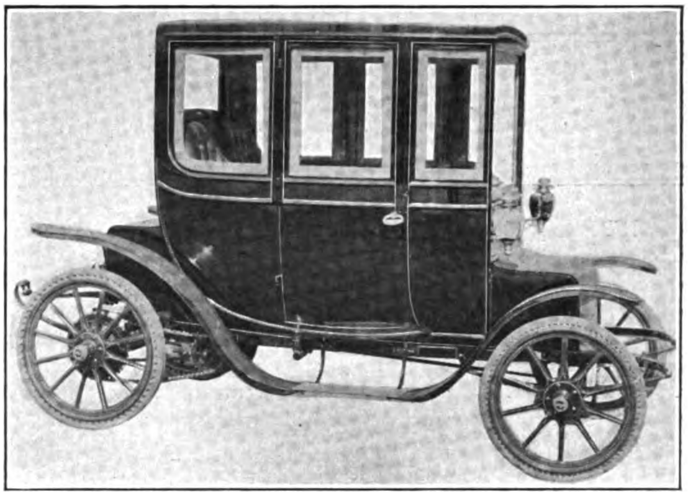

Fig. 1—Ideal Electric town car with inside control

The car is built up on a chassis frame of the I-section, of dimensions to render it wholly unnecessary to rely upon the body framing to support any of the load, and the method of bracing the side bars is that which obtains in regular practice in the construction of gasoline types of automobiles. The motor suspension is so devised that the side chains are relieved from undue strains, and alignment is brought about and maintained through the use of distance rods that are sufficiently strong to withstand the work that is likely to be put upon them in severe service.

Exide Battery is Used in the Ideal

Reliance is placed upon the Exide battery in the cars of this make, and the number of cells as well as the number of plates per cell is determined by the service to which each car is to be devoted. Preference is given ample battery equipment rather than to skimp with a view to economy of weight or to lower first cost.

In view of the general character of the service to which electric vehicles of this class are put, the greatest attention has been given to the details of the battery installation. If, in the course of events, it is found desirable to remove the battery for purposes of cleaning, it may be accomplished in the shortest possible time by the owner, or if a man is in charge of the car, it is not necessary for him to be a battery expert. All the connections are carefully identified and the method of marking is such that, in putting the battery back into the car, it can only be done in one manner and that is the right way. The work of charging the battery is much simplified, and the chances of damaging the battery are reduced to a remote contingency. The cost of maintenance of the car is held at a lower level in this way.

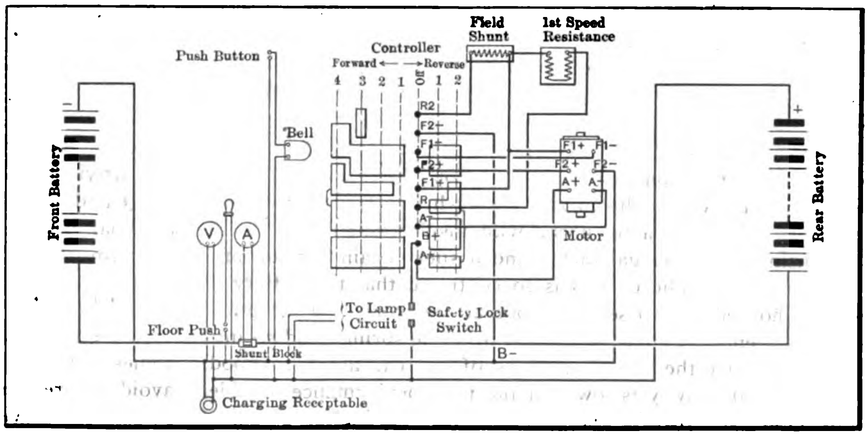

Fig. 3—Wiring diagram arranged for a unit motor and the battery in two parts, designed to give four forward and one reverse speed

Graham Differential

PRESENTING A CROSS SECTION IN TWO PLANES OF THE GRAHAM DIFFERENTIAL GEAR WHICH IS OF THE OVERHAULING TYPE. ALSO DETAILS OF DESIGN AND CONSTRUCTION

DIFFERENTIAL gears of the conventional type consist of a system of planets engaging similar suns. They are so contrived and arranged that they weigh out the torque of the motor, conforming to the conditions as follows:

(A) If the automobile is traveling straight ahead on a hard level road an equal amount of power is delivered to each traction wheel, and the differential-gear system remains inactive just as though the two wheels were attached, having an axle between them.

(B) When the automobile is turning around the corner, the differential gear permits one wheel to rotate faster than the other, but it delivers power to both wheels if the traction conditions are the same for each of them.

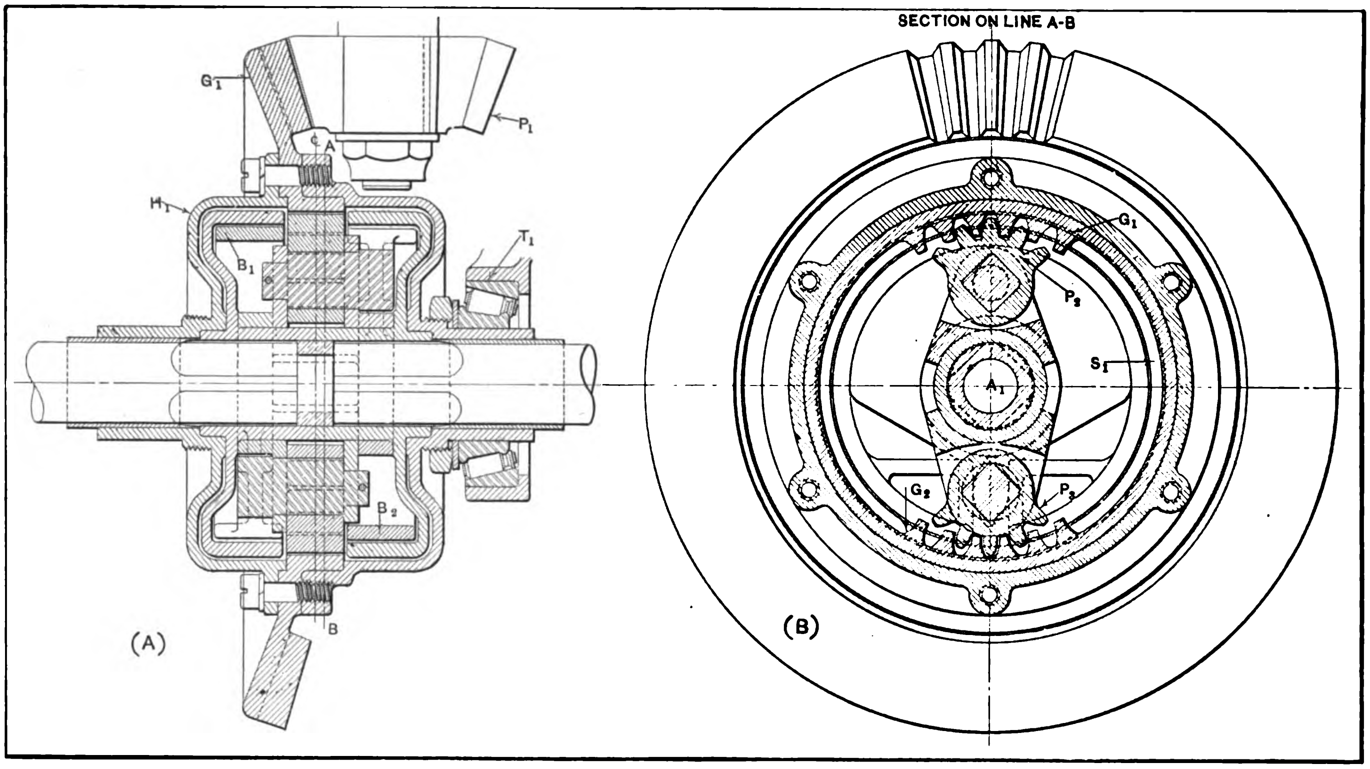

Fig. 13 (A)—Longitudinal section of assembled differential gear; (B)—Cross section of the same

(C) If the road condition is varying and one of the traction wheels drops into a soft spot, the amount of power that may be taken by the other is reduced by the lack of traction of the wheel resting on the soft spot, and if the conditions become sufficiently bad the wheel that is resting upon the soft spot will turn backward and the other wheel will stand still so that effective traction is defeated.

The reason for using a differential of this type is to permit of driving on a curve without having to slip one of the wheels. The disadvantage (C), while it represents a serious condition that must be reckoned with, is less than that which would obtain were there no means for preventing slipping when an automobile is going around the curve.

The Graham differential gear, as illustrated in Fig. 13, shows a section parallel to the axle at (A) and a section at right angles to the axle at (B). This gear is manufactured by the Graham Differential Gear Company, with an office at 2123 Michigan avenue, Chicago, Ill., and the principle of operation departs from the conventional type of differential gear sufficient to overcome the ills as referred to in (C) involving the performance under bad road conditions, offering at the same time the facility referred to in (B) in that the automobile is permitted to go around a curve without dragging one of the wheels.

The particular axle shown in Fig. 13 was gotten up to include the use of Timken roller bearings, one of which is indicated at T1. The bevel pinion P1 meshes with the bevel gear G1 in the regular way. Briefly stated, the construction as indicated is such that when an automobile is going around a curve the outer wheel, which must travel the greatest number of revolutions, is permitted to go faster than the inner wheel, but the load is taken by the inner wheel during this period unless it enters a soft spot on the road, when if it slips the outer wheel takes the work. If the outer wheel can travel faster than the inner wheel, provided the roadbed is firm, it stands to reason that the inner wheel if it slips will overhaul the outer wheel, which the construction permits, in which event the outer wheel will take the work until the time arrives when the inner wheel is permitted to take up its burden again.

Referring to (B), Fig. 13, P2 and P3 are pinions, each on independent spiders revolving around the axis A1. These pinions mesh in the teeth of the internal gear at G1 and G2 on the common spider S1. One pinion P1 is rigidly attached to one of the jackshafts, and the other pinion P2 is rigidly attached to the remaining jackshaft. Referring to (A), Fig. 13, there are two brake bands, B1 and B2, which are actuated when power is applied through the pinion P1 from the motor by way of the propeller shaft, thence to the gear G1, and finally to the housing H1. From the housing H1 the power is transmitted to the teeth G1 and G2 of the spider S1, causing the pinions P2 and P3 to

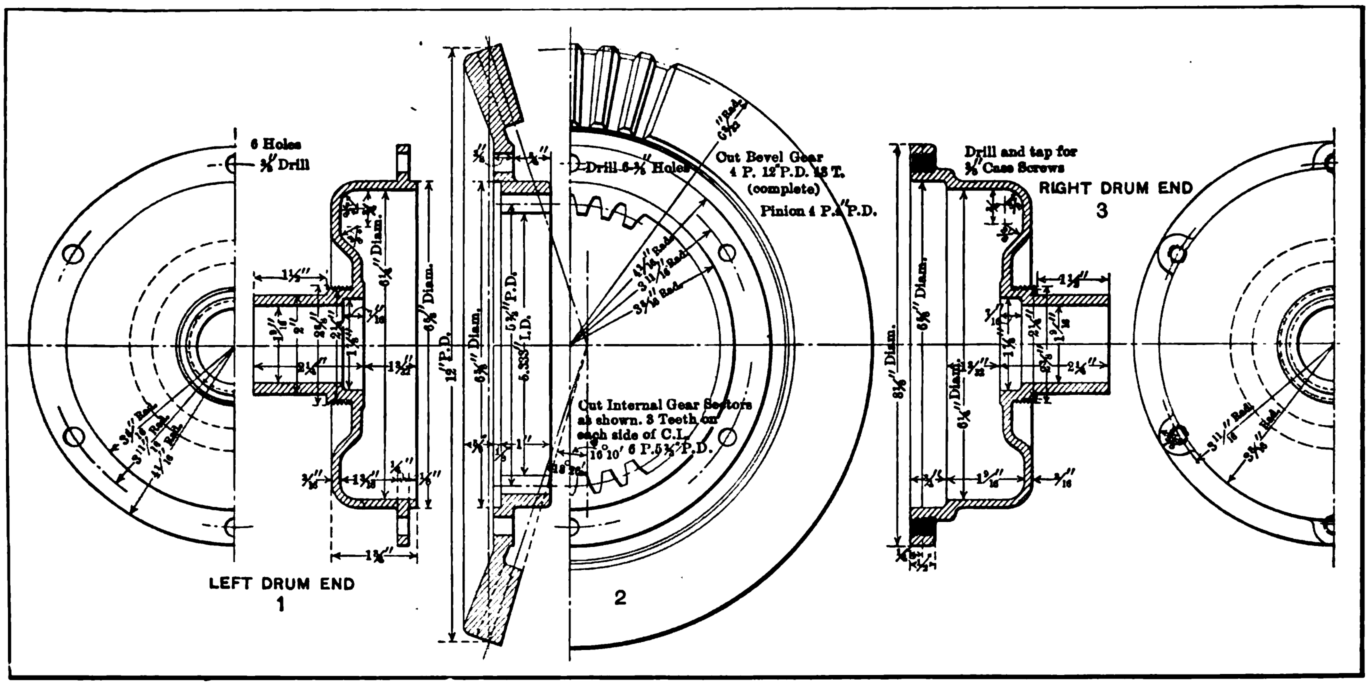

Fig. 1—Left drum end; Fig. 2—Bevel gear; Fig. 3—Right drum end

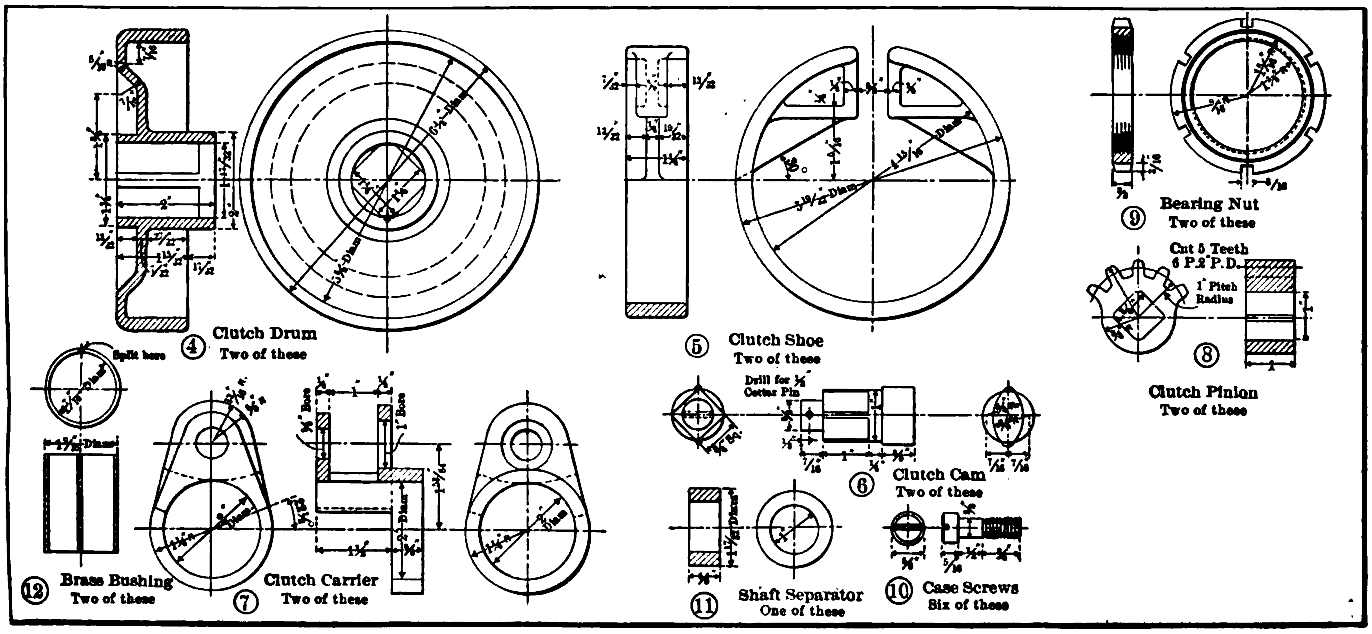
rotate, thus imparting motion to a cam, which in turn expands the brake bands, and completing the drive.

It is possible for one wheel to rotate faster than the other, due to the simple process of overhauling and the straightening up of one of the cams in response to the motion. Under such conditions the remaining cam and one of the brake drums in rigid relation with its band afford the means of driving. Under ordinary conditions the inner wheel does this work, but it is not essential to success that either of the wheels does the driving. As the construction shows, the wheel that travels the slowest is the one on which the work will come. This low speed may be due either to the negotiation of a curve or lack of traction of the other wheel.

The brake bands are provided with cork inserts and they carry the load with great certainty, due to the fact that the bands are expanded before rotary motion is imparted to the members, so that relative motion is obviated. Moreover, the construction is such that the pressure causing expansion of the bands increases in greater proportion than the torque, hence the conditions that are ordinarily chargeable to the failure of brakes are eliminated.

The proportions of the Graham differential are such that it will go in the housing as ordinarily provided for conventional differential gears, and the weight of the mechanism compares favorably with the other means at hand. A better understanding of the needs will be found by glancing at Figs. 1, 2 and 3, representing the left drum end, the large bevel gear and the right drum end respectively, they being shown in plan and section. Considering the importance of differential gear systems, and the necessity of having the parts of good design and stable, it was deemed expedient to reproduce here all the parts employed in this gear, so that Figs. 4, 5, 6, 7, 8, 9, 10, 11 and 12 are given as representing the miscellaneous parts and fittings required.

It may be interesting to observe that the conventional types of differential gears offer unusual disadvantages under certain conditions, as when the roadbed is poor and the load is heavy. The Graham differential is being taken up to supplant other types of gears under these severe conditions, and it seems to be efficacious for the purpose.



Figs. 4 to 12, inclusive—Parts to scale with sizes given

The Halladay Automobile

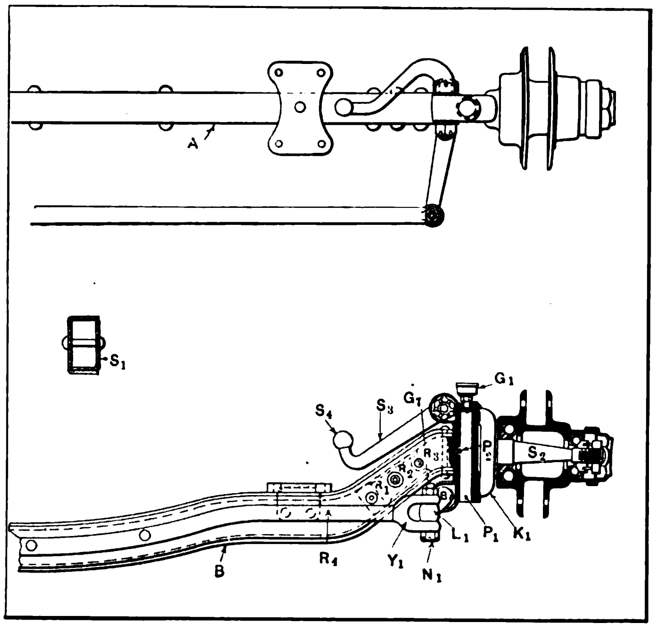


Fig. 2—Plan and section of A. O. Smith type of pressed-steel front axle using cup-and-cone ball bearings

RECOGNIZING the necessity of being able to give to a discriminating clientèle the character of automobiles it expresses a preference for, the Streator Motor Car Company, Streator, Ill., builder of the "Halladay," presents for 1911, among its several models, the Model 40, which is the subject matter here. The specifications of this car are offered in tabular form for the sake of brevity and utility, and the general appearance of the car, as it is designed for touring, is shown in Fig. 1. Referring to the design of the body, it is of the convertible type, i.e., if the purchaser elects to take a touring body as shown in Fig. 1, it is with the understanding that it can be converted into a "gunboat" at short notice and small cost. Just how this is accomplished is shown in the illustration of the body, and the method of doing the work is clearly described in connection therewith.

Points of Note in the Front Axle Design

The front axle is shown in Fig. 2 in plan at A and in part section looking at the front in B. The axle is of the A. O. Smith pressed-steel type, the section of which is shown at S1. Referring to the front view B, the knuckle casting is a close fit in the pressed-steel axle and is riveted at R1, R2 and R3. The knuckle pin P1 passes clear through, is prevented from dropping out by a tangent pin P2, and has a grease cup G1 at the top. The knuckle K1 is a drop forging of special steel, annealed to subdue internal strains. The spindle S2 is machined and ground so that the inner races of the cup-and-cone bearings are a sucking fit. The cross rod R4 is of large diameter of annealed drawn steel tubing, with a yoke Y1 with liberal bearings accommodating its mate on the end of the lever L1, and the hardened bolt B1 is provided with a grease cup G2 in its head, and a castellated nut N1, with a locking pin at the other end. The steering arm S3 is of special steel with a large diameter sphere S4 on its end, which accommodates the socket of linkage between it and the arm on the steering post. The material and workmanship throughout are up to a fitting standard, with all the parts carefully heat treated to induce a proper measure of kinetic ability. Referring to Fig. 3 of the live rear axle and torsion tube combined, it will be observed that drawn and pressed steel tubings and housings are used throughout. The differential gear system D1 is of the bevel type, and the jackshafts J1 and J2 have square ends S1 and S2 where they fit into the "suns" of the differential system. Cup and cone bearings are employed at every point with locking adjustments so arranged that lost motion may be taken up if in the course of time it is developed.

SPECIFICATIONS OF HALLADAY

MODEL			BODY		MOTOR				COOLING		IGNITION		
	Price	H.P. A.L.A.M.	Type	Seats	Cylinders	Bore	Stroke	Cyl. Cast	Radiator	Pump	Magneto	Battery	Lubrication

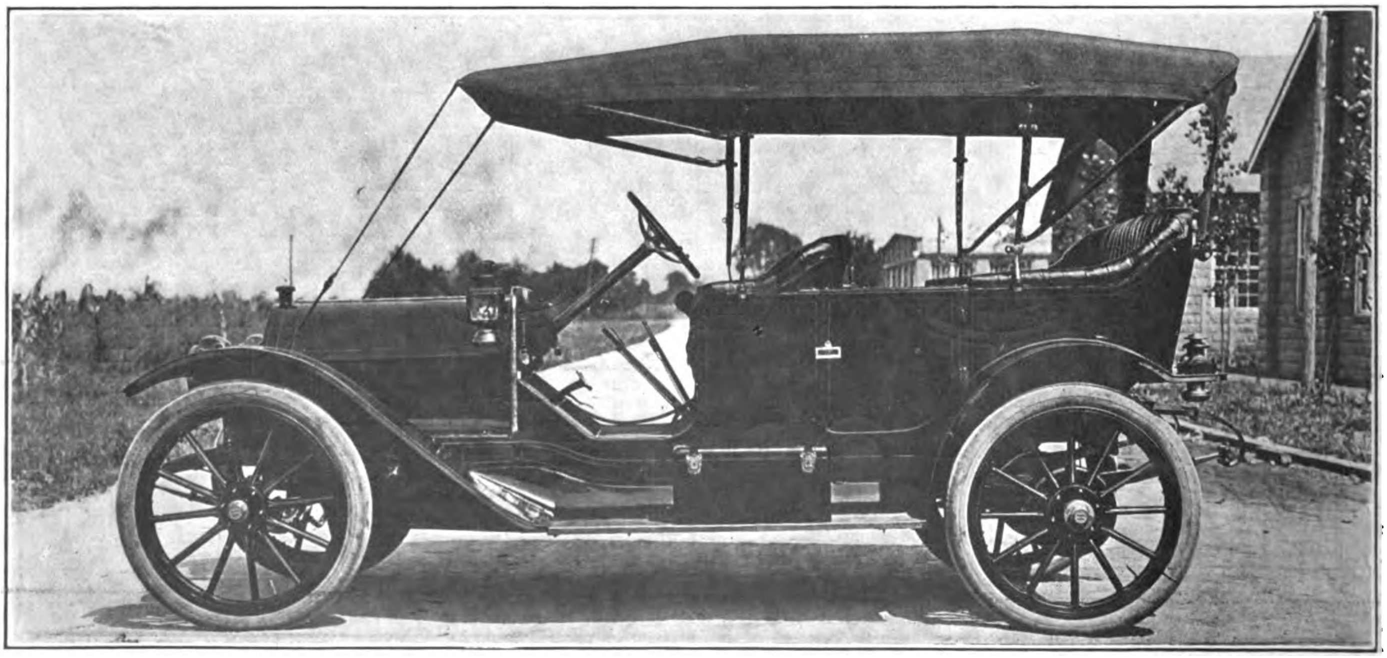

Fig. 1—Model "40" Halladay with a conventional straight-line touring body and means for converting same into a gunboat at any time

FOR 1911. THIS IS SO MADE THAT IT CAN BE CONVERTED FROM A NORMAL TOURING TYPE TO A FORE-DOOR PROPOSITION

The bevel pinion shaft S3 has two bearings B1 and B2 with a considerable spacing between them, and the pinion P1, which is carried by the bearing B2, is fitted close up to the bearing so that the cantilever effect is reduced to a minimum. The torsion tube T1 is shown in two planes, and the universal joint J3 at its extremity is relatively large, fitting into a socket which in turn is supported by a substantial cross member of the chassis frame. The hub H1 shown at the right is accurately machined, and driving takes place through a jaw J4 so that the construction has all the virtues of a floating system. The brake drums, one of which is shown at B3, are of large diameter, housing the brakes B4 and B5 alongside of each other, so that both the service and emergency brakes are of the internal expanding type, hence protected from the silt of the road and rendered effective by a straight line system of links and levers.

The Multiple Disc Type of Clutch and Housing

The clutch used is of the multiple disc type as shown in Fig. 5 and is flanged on the flange F1 of the crankshaft, being centered at C1 and securely bolted in the manner as shown. The driven member D1 rotates on a plain bearing with a bushing B1, and the discs D2, of which there are a suitable number made of saw-blade steel, have the especial virtue of being conical on their friction faces, and it is also worthy of note that the driving faces D3 for the outside and D4 for the inside are extra large. The housing H1 is oil tight and the cover C2 has a bearing B2 at the shaft and an oil tight joint J1 where it fits the housing H1. The clutch spring S1 has seven turns, using a large diameter wire, thus affording a sufficient pressure to prevent the clutch from slipping under the most severe conditions. Thrust is taken by a ball bearing D3, and one member of the universal joint U1 is shown in place on the taper of the shaft with a locking nut L1 to hold it in place. The clutch is released when the pedal is pressed with a pressure of approximately 40 pounds, which pressure is transmitted to the trunnions T1 and T2 through a suitable motion.

"40" AS OFFERED FOR 1911

	TRANSMISSION							BEARINGS				TIRES	
Clutch	Type	Speeds	Location	Drive	Wheelbase	Tread	Frame	Crankshaft	Transm's'n	Axle	Weight	Front	Rear
Mul. Disc.	Selecti'e	3	Unit	Shaft	118	56	P. St'l	Plain	Ball	Cup and Cone	2750	36x3½	36x3½

An Innovation Resides in the Touring Body

The Model Forty body is shown in Fig. 6 with the plan at A, side elevation at B and cross section at C. All dimensions are given and the general appearance of the body when it is entirely completed, as per plan, is that of a fore-door type along gunboat lines. The innovation hinted at is involved in the construction by means of which the body may be delivered to the purchaser as a strictly touring type, without fore-doors, but the arrange-

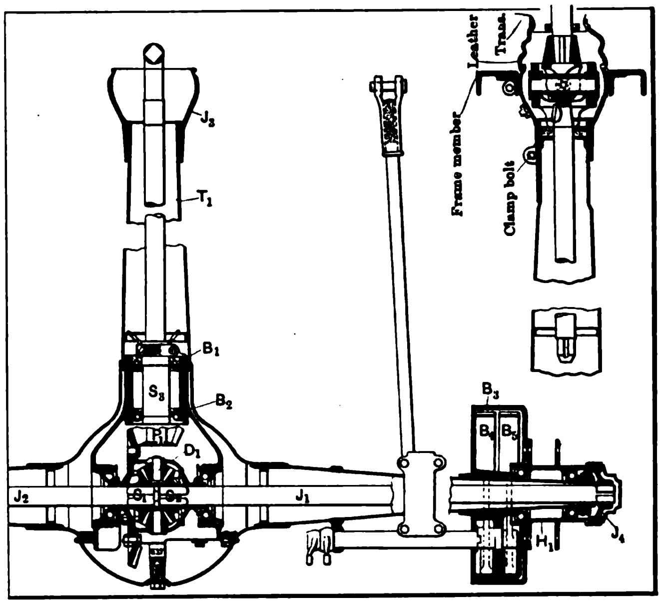

Fig. 3—Pressed-steel type of live rear axle, section to show bevel differential and two pairs of internal expanding brakes

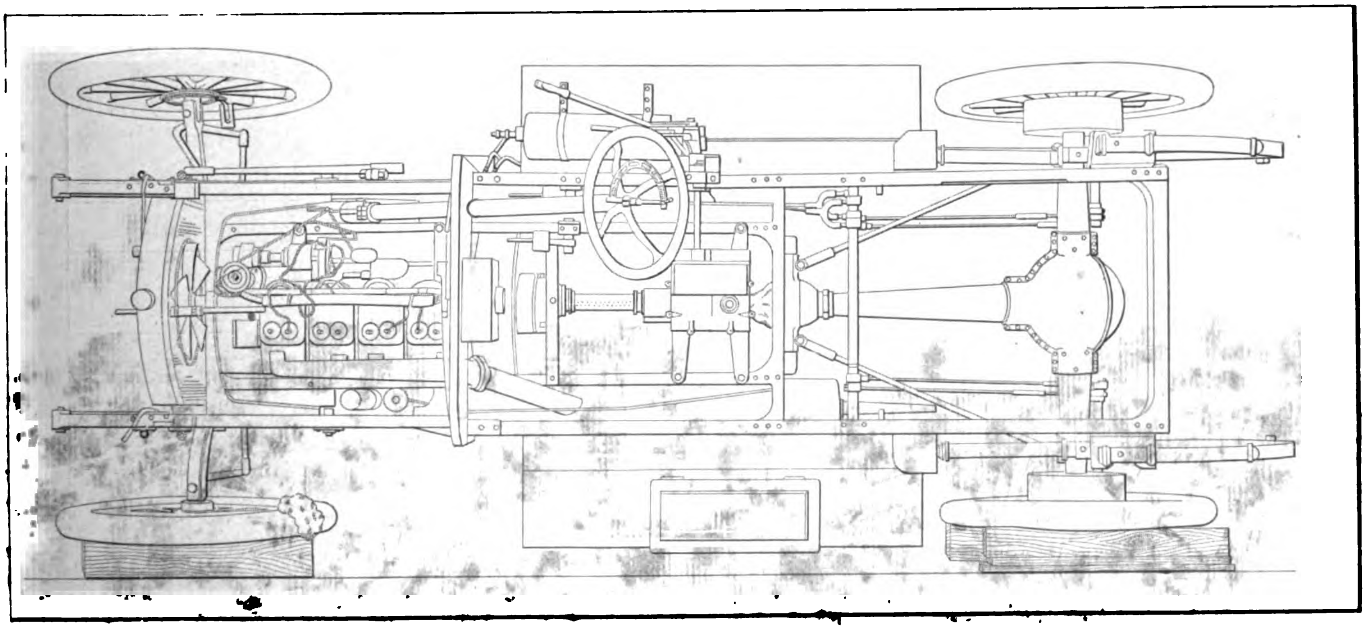

Fig. 4—Stripped chassis, showing relations of units mounted on the double-drop I-section frame. This wax cut was made from a photograph of the car as it stood on blocks, resting on two wheels

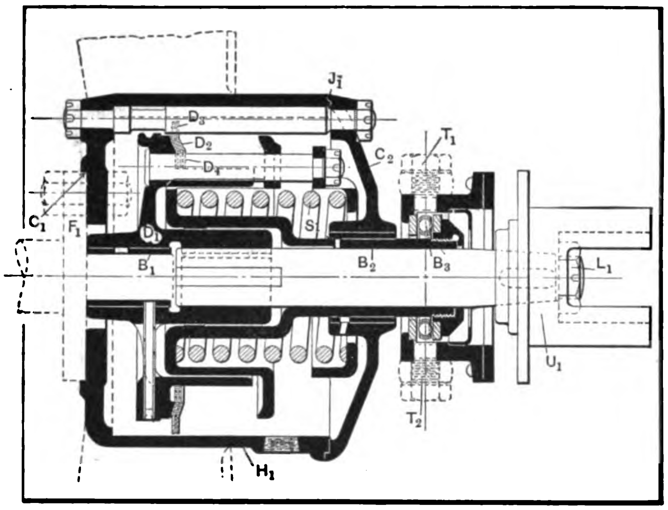

Fig. 5—Multiple-disc clutch within the flywheel confines, with a stout spring and ball-thrust, and an oil-tight housing

ment of the framing at the front is such that the fore-doors may be added at any time at no great cost and without delay.

A close examination of the front end of the body as depicted in the side elevation B will show the dash D1 with a cowl C1 fitted over it, sweeping back to the jam of the door J1, supported around the rim R1 by a bead and at the lower point by the footboard F1 as well as at the framing below. The fore-door is shown in the section through EE, and a foot note at the bottom states "sills must be made to fit sillplates." The design includes an aluminum accommodation piece which is so fashioned that it will fit readily into place on the regular touring body, and by removing the old dash and substituting the new one as before described the entire undertaking is consummated without having to alter the body in any way, but the finished appearance is up to the most exacting demand so that the autoist who purchases a car of this make may have his choice of this car with a touring body of the conventional type with the full understanding that it will be converted to a fore-door type of body at any later date, thus giving him a choice and an option. The character of material, workmanship and finish as represented in this body is in keeping with the latest and most approved practices.

Worm and Sector Steering Gear with Ball Thrusts

The importance of a substantial steering gear is recognized as fitting, and the Gemmer type of worm and sector gear as shown in Fig. 7 is used on this car. The worm W1 is of hardened special steel, meshing with the sector S1, which in turn is pressed onto the shaft S2, and keyed by the key K1. The housing H1 is oil tight and thrust is taken by thrust bearings T1 and T2. The spark and throttle control is interpreted by bevel systems B1 and B2, driven by concentric shafts S3 and S4 within the worm shaft, with a protecting shell outside. The steering wheel W2 is of mahogany, fitted over the rim R1 of the spider, and the spider is keyed to the shaft (on a taper) using two Woodruff keys K2 and K3. It is also pressed down by means of a nut N1. The spark and throttle control levers are shown in part section above the steering wheel. The section A in the left bottom corner of the illustration affords another view of the worm and sector, thus rendering the whole construction sufficiently clear to make further discussion unnecessary.

Annular Ball-Bearing Type of Transmission Gear

The scheme of design of the transmission gear is shown in Fig. 8, which is a section in the vertical plane, cutting through

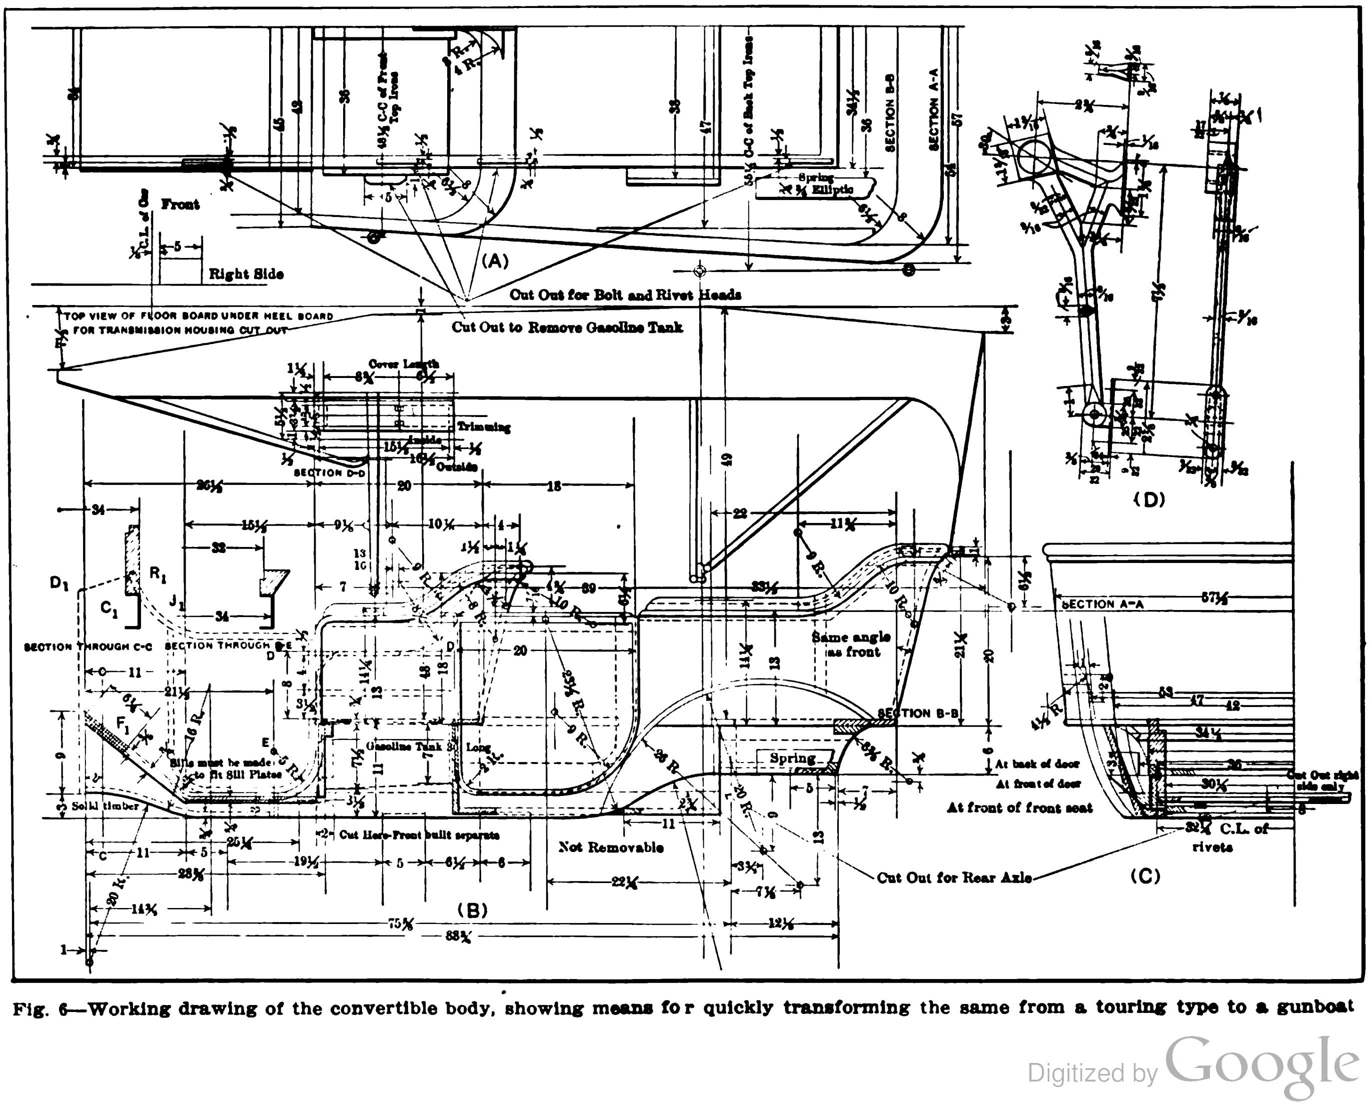

Fig. 6—Working drawing of the convertible body, showing means for quickly transforming the same from a touring type to a gunboat

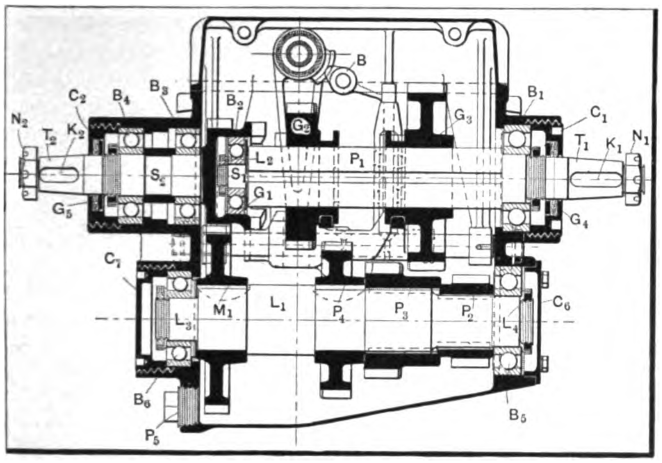

Fig. 8—Section of the transmission gear of the selective three-speed type with stout spindles centered on F. & S. annular ball bearings

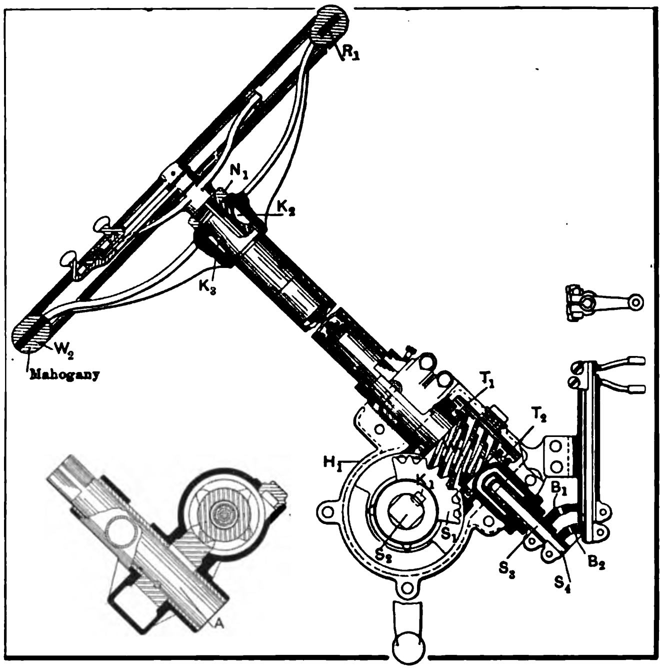

Fig. 7—Worm-and-sector type of Gemmer gear with internally located concentrically disposed spark and throttle mechanism

the prime and lay shafts. Referring to the prime shaft P1, which is directly above the lay shaft L1, it is centered in a large annular-type ball bearing G1 at the end, and where it engages the jaw drive a ball bearing B2 is a sucking fit on the shouldered portion of the shaft S1 with a locking nut L2 placed to hold the inner race in secure relation. The outer race is a hand fit in the bore of the internal gear G1 with endwise freedom. The ball bearing is therefore in a position to do its work without having to resist thrust, and the design is such that the bearing affords a relatively large factor of safety. The sliding gears G2 and G3 are fitted over the square shaft P1, and the pinion for low gear P2 on the lay shaft L1 has a large surface, is a press fit and is provided with two keys. The pinions P3 and P4 as well as the master gear M1 are also keyed on, but they are so much larger in diameter than the pinion P2 that trouble from this source is not to be anticipated. The stub end shaft S2 has two ball bearings B3 and B4 with center distances between them sufficiently great to eliminate lost motion. The lay shaft L1 is provided with large ball bearings B5 and B6 with a sucking fit on the shouldered portion of the shaft on each end and locking nuts L3 and L4 holding the inner raceway securely in place while the outer races are a hand fit, hence self-aligning. Both shafts are of large diameter and relatively short; deflection is therefore aborted and the ball bearings throughout are provided with closures in the most approved way. For the prime shaft the closures C1 and C2 screw into place, making the housing perfectly tight, and oil is prevented from migrating out by the grooves G4 and G5. The lay shaft covers or closures C6 and C7 are not provided with openings because the shaft does not protrude through. The universal joints are fetched up on tapers T1 and T2 on a basis of 1½ inches to the foot, the idea being to provide a slow taper so that a small amount of pressure will force the joints on so that they will withstand the torsional effort without requiring the keys K1 and K2 to do very much work. Castellated nuts N1 and N2 are provided and screw up against the hubs of the universal joints, forcing them up upon the tapers, after which the castellated nuts are locked. At the lowest point in the aluminum case a 1-inch taper plug P5 is provided, by means of which the whole interior of the case may be flushed out, thus making it possible to clean out "shabby" lubricating oil, replacing it with new "slippery" product. There are other nice features that might be lingered upon, but the general character of the design, construction and workmanship of the transmission gear are brought out in sufficient force to satisfy the purpose here.

Coming Events

CALENDAR OF FUTURE HAPPENINGS IN THE AUTOMOBILE WORLD THAT WILL HELP THE READER KEEP HIS DATES STRAIGHT—SHOWS, RACES, HILL CLIMBS, ETC.

Dec. 1	Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.
Dec. 31-Jan. 7, '11	New York City, Grand Central Palace, Eleventh Annual International Automobile Show.
Jan. 7-14, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Manufacturers.
Jan. 16-21, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Jan. 28-Feb. 4, '11	Chicago Coliseum, Tenth Annual National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Pleasure Cars and Accessories, Exclusively.
Feb. 6-Feb. 11, '11	Chicago Coliseum, Tenth National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Commercial Vehicles, Pleasure Cars, Motorcycles and Accessories.

Races, Hill-Climbs, Etc.

Aug. 16-27	Munsey Tour.
Aug. 26-27	Elgin, Ill., Road Race, Chicago Motor Club of Chicago, Ill
Aug. 31	Minnesota State Automobile Association's Reliability Run.
Aug. 31-Sept. 8	**Kansas City, Mo., Reliability Run, Auto Club of Kansas City.**
Sept. 2-5	Indianapolis, Ind., Speedway Meet.
Sept. 3-5	Run and Labor Day Race Meet of North Wildwood Automobile Club.
Sept. 3-5	Brighton Beach, Two-day Track Meet.
Sept. 5	Cheyenne, Wyo., Track Meet.
Sept. 5	Denver, Col., Road Race, Denver Motor Club.
Sept. 5	Los Angeles, Cal., Speedway Meet.
Sept. 5-10	Minneapolis, Minn., Track Meet at State Fair.
Sept. 7-10	Buffalo, N. Y., Reliability Run, A. C. of Buffalo.
Sept. 9-10	Providence, R. I., Track Meet.
Sept. 10	Los Angeles, Cal., Mount Baldy Road Race.
Sept. 10	San Francisco, Cal., Golden Gate Park Road Race, Automobile Club of San Francisco.
Sept. 10-12	Catskill Reliability Contest and Hill Climb, Motor Contest Association.
Sept. 10-12	Seattle, Wash., Race Meet.
Sept. 15	Algonquin, Ill., Annual Hill Climb of Chicago Motor Club.
Sept. 16-26	Asbury Park, N. J., Aviation Meet, Aero Club of America.
Sept. 17	Syracuse, N. Y., Track Meet of Automobile Club of Syracuse, Syracuse Automobile Dealers' Association and the New York State Fair Association.
Sept.	Chicago, Commercial Car Reliability Contest of Chicago Automobile Club.

PURCHASERS are much concerned about the body problem this year. Will they be safe in acquiring a conventional type of touring body or will the fore-door type prevail?

* * *

AUTOMOBILE bodies and millinery, are discarded when they go out of style. It is at some cost in both cases.

* * *

WHEN millinery is discarded the head of the owner is retained and it is usually capable of further service. When an automobile body is rendered *hors de combat* by the dictator of style the whole contrivance, including the body, is disposed of at a small part of the total cost.

* * *

ECONOMISTS are watching the automobile industry, hoping, perchance, that some way will be found to prove to the average mind that it is an economic waste.

* * *

HOMBRE de un libro (man of one book), the average economist, looks through a dollar, or for a dollar-owner, more likely than not, but the fact remains that it is a gross extravagance to cast off a $2,000 automobile to get rid of a $400 body.

WHAT is the right solution of this vexing problem? Is it to come by educating the owner, who, lacking in stamina, abandons a serviceable body just because Jones, his neighbor, has one that looks different?

* * *

CONVERTIBLE bodies offer attractions from this point of view, and it is the plan of at least one maker this year to offer an option with the body. If the purchaser elects to acquire a conventional type of touring body it will be with the full understanding that it will be converted into a fore-door type of body at any later date if the purchaser so wills it.

* * *

GAUGING the automobile business is a process that can only be conducted successfully if the instrument of precision employed is one that will present the result in known and well-recognized terms. The breaking of the record by the Stearns car at Brighton Beach, advancing the standard 57 miles from 1,196 to 1,253 miles in twenty-four hours, represents something of the real advance that the automobile has made within a year.

* * *

BUT the situation is considerably better than is shown by this new record. Tire trouble interfered seriously with the performance not only of the Stearns but of the other contestants.as well. To whatever extent tire trouble retarded this performance account should be taken, and in the final sum-up it must be remembered that the strain on a car increases as the velocity square. In interpreting this statement it is equal to saying that there is no test to which an automobile can be put that is equal to a record-breaking run on a circular track.

* * *

APROPOS of the tire problem it may not be out of place to call attention to the fact that the main proportion of it is due to running on partially inflated tires. The autoist who prefers to use the tires in the capacity of springs will find them high-priced for the purpose. The man who sets up the claim that a tire is fully inflated simply because he is wearied of pumping is, of course, wrong. What he needs is a power pump.

* * *

BUDDING autoists are the most inclined to jump to the conclusion that cotton, as a fabric, is lacking in strength, hence incapable of sustaining under considerable pressure. It is a great mistake to undertake to relieve a tire from pressure by the infernal expedient of running it in a partially inflated condition.

* * *

THE fact that a tire is not wholly inflated by the man who injects the air into it will not reduce the working pressure by a hair. When the weight of the car together with the inertia component comes on the partially inflated tire, the working pressure will be just as high as it would be under fully inflated conditions. There is the added misfortune of flexure with a partially inflated ire, to which must be ascribed the greatest reason why tires do not last too long.

Detroit Trade News

HAPPENINGS OF THE WEEK IN THE AUTOMOBILE MANUFACTURING CAPITAL—NEW CORPORATIONS, FACTORY GLEANINGS, NEW AGENCIES, TRADE CHANGES, ETC.

DETROIT, Aug. 22—Another accession to the ranks of small car makers is the Whitney Motor Car Company, which has just been incorporated with a capital stock of $150,000. It is the intention to manufacture a gearless friction drive roadster that will sell around $400. Brock C. Eby is president of the company; J. C. Hudson, vice-president; H. C. Whitney, secretary, and George O. Taeckels, treasurer.

The recently organized Universal Motor Truck Company has filed articles of incorporation, placing its capital stock at $350,000. Coincident with this, C. H. Haberkorn has resold to the Universal Motor Truck Company the factory site he recently purchased in the north end of the city, and ground will be broken this week for the new plant.

The Paige-Detroit Motor Car Company has increased its capital stock from $100.000 to $250,000, in anticipation of large extensions for the coming season. James Borquin, superintendent with the Chalmers Company since its inception, has severed his connections with that concern, and becomes general factory manager for the Paige Company, which means a livening up all along the line.

Commencing September 1, the Maxwell-Briscoe-McLeod Company, Michigan distributors for Maxwell and Columbia cars, will change its name to the United Motor Detroit Company, in conformity with the plan being followed wherever selling branches of the United States Motor Company are found.

Edward R. Hewitt, of New York, is now a stockholder in the Metzger Motor Car Company and one of its staff of technical experts. Mr. Hewitt was for years the moving spirit in the Hewitt Truck Company, taken over by the Metzger people about a year ago. Since that time he has been identified with the same line, but henceforth the benefit of his experience will be given to the pleasure as well as commercial cars being turned out by the Metzger Company at its Detroit plants.

A "sociability" run will be held by Detroit motor enthusiasts next Sunday, and to arouse added enthusiasm Albert R. Smith has donated a handsome silver loving cup as a trophy to the driver making the nearest approach to the time Mr. Smith occupied in covering the course. The road leads from Detroit through Plymouth, Pontiac, Utica and back to this city. From the number of entries received the run promises to be a great success.

The Michigan Buick Auto Supply Company has filed articles of incorporation, with a capital stock of $2,000,000.

The E-M-F Company has leased the four-story brick structure at Fourth and Abbott streets, just vacated by the Detroit Bag Company, and will devote it to some of the many ramifications of the motor car business as conducted by this concern.

Quite the most interesting bit of personal news to local automobile circles comes with the acquisition by the Hudson Motor Car Company of Edward H. Broadwell, vice-president of the Fisk Rubber Company. Mr. Broadwell recently acquired stock holdings in the Hudson company, and has been elected second vice-president of the company. He will assume complete charge of the selling end of the business, and will have as his assistant sales manager E. C. Morse. "Ned" Broadwell has been associated with the motor car industry from its inception, and for the last ten years had been with the Fisk Rubber Company, the last five years serving as vice-president. He assumes his new duties September 1.

The Ford Motor Company has begun the erection of a $30,000 addition to its Canadian plant, located just across the river, in Walkerville. When completed this will give 20,000 additional square feet of floor space. Work is also being rushed on the company's new salesroom at Woodward avenue and the Boulevard. The structure, which will be ready for occupancy late next month, is of reinforced concrete, 100 x 100 feet on the ground, and three stories in height, although it is the intention to ultimately increase it to eight. When completed it will be one of the most imposing showrooms in the city.

The Wagenhals Commercial Motor Car Company, of St. Louis, Mo., will shortly locate in Detroit and engage in the manufacture of a three-wheeled light delivery car, which combines many novel features, chief of which, of course, is the elimination of the customary rear axle, differential and other standard parts.

As usual, the automobile is proving a strong factor in the political campaign now being waged throughout the State. Chase S. Osborn, who is seeking the Republican nomination for Governor, has been touring Michigan in a Regal car for some weeks. Other candidates who find the railroads inconvenient are employing similar means of transit, and are covering four and five towns a day, whereas under the old way but two towns could be covered.

The first light delivery cars for the Van Dyke Motor Car Company began coming through the west side factory last week, and it is expected that in a short time the plant will be turning out twenty-five machines a day.

Pending the completion of a magnificent garage at Woodward and Alexandrine avenues, ground for which has just been broken, the Elmore Motor Car Company has established a temporary agency for Michigan and Canada at 295 Jefferson avenue, with M. A. Young in charge. The business here will be conducted under the style of the Elmore Automobile Company and a complete line will be carried.

Some two dozen Cadillac sales agents from all parts of the country organized an association known as "The Old Guard" in Detroit recently. Each member has been in the service of the company at least five years. The association will meet three times a year, in January at New York, in February at Chicago, when the auto shows are on, and in Detroit at the time the new model is ready for the market. G. E. Blakeslee, of Jersey City, the oldest sales agent in the company employ, was elected president. I. M. Uppercu, of New York and Newark, was chosen secretary and treasurer. There are no other officers.

The Lion Motor Sales Company has been organized with a capital of $10,000 to handle the Lion car, made in Adrian, Mich. The officers are: Fred Postal, president and treasurer; Robert L. Fee, vice-president and manager, and Harry Postal, secretary. The same men constitute the Michigan Motor Sales Company, 650 Woodward avenue.

Another Selden Injunction Issued

An injunction has been served by United States Marshal Henkel on C. A. Duerr & Co., of New York, who were formerly agents of the Ford Motor Company in New York, restraining them from making, selling, or using cars infringing the Selden Patent.

Duerr & Co. were defendants in the same suit as that brought against Ford Motor Co., and the injunction now granted against them was served on Charles A. Duerr as president of the company, and Lindsay Russell, as trustee in bankruptcy for the company.

Charles A. Duerr is now New York distributor for a licensed car and the effect of the present action will be to enjoin him from selling anything but cars manufactured under Selden Patent license.

Ready at Elgin

BIG FIELD OF CRACK CARS AND DRIVERS ON HAND FOR THE FOUR BIG RACES

CHICAGO, Aug. 23—Given the same kind of weather as prevails to-day, the national stock road chassis races at Elgin on Friday and Saturday of this week should be the greatest stock car speed carnival that ever has been run on a highway. The Chicago Motor Club, which is putting on the show, has succeeded in getting together a most brilliant field of cars, which are thoroughly representative of the American industry, there being only one foreigner—a Benz in the small car race.

With about all the star drivers in the big race of the meet, the 300-mile Elgin National on Saturday, there should be excitement enough to suit the most fastidious motor enthusiast. The main race of the first day, the Illinois Trophy, has attracted eight entries, which include the National, Falcar, KisselKar, Midland, Marmon and Lexington. In the Kane County there are seven, which takes in the Corbin, Overland, Marmon, Marion, KisselKar and Cino. The Fox River Trophy event, in which the little cars will compete, has eight contenders, three of which are Stavers, two Fords, Warren-Detroit, Cole and Benz. In all, there are thirty-six entries for the four events, representing twenty-two different makes of cars. One that came in at the last minute was the third Staver.

The drawing for numbers took place this morning and the luck of the draw gave No. 1 to Arthur W. Greiner, the Chicago amateur, in the Elgin National event, in which he will pilot a National 40. The National also was fortunate in the Illinois trophy, No. 1 in that event going to Livingstone, the other driver on the team. Joe Matson in the Corbin pulled out the first postion for the Kane County trophy for his car, while the Fox River drawing resulted in Frank Kulick in a Ford drawing first position, although his number is 31. The drawing also showed a switching about of drivers. The Marmon people decided to save Harroun for the last day and put Dawson in the Illinois in Harroun's place, while Louis Heinemann took Dawson's seat in the Kane County. The KisselKar people substituted H. Endicott for Schoeneck in the big race and saved the latter for the Kane County.

While some of the teams have been in camp at Elgin for more than a week, activities in the training line did not start until yesterday because the course was not completed until the latter part of last week. The circuit was in shape for practice on Friday, but it was decided that it would be better to wait until Saturday. However, when Saturday came there was a heavy rain in the morning so that it was deemed best to postpone the practice until Monday. All conditions were favorable yesterday and some fifteen or sixteen cars were out for their first trial. There was no disposition on the part of any of the drivers to go the limit on their first appearance and most of the two hours of practice was taken up in becoming acquainted with the course. However, there were several bursts of speed, and there were several laps at better than 60 miles an hour. Grant, Harroun, Livingstone and Mulford were among those to show the capabilities of the course in this manner. The drivers declared that the circuit was in admirable shape for the racing and the first day at practice proved that the road commissioners had done their work well. The straightaways were hardly disturbed by the cars and not marked up in the least. Two of the corners stood the gaff well, but the turn at Hornbeek's, which is at the southeast corner of the circuit, was cut up some because of the fact that big trees overshadowed the road so the sun cannot get in its best licks. There was more practice to-day despite the fact that during the night there was a heavy thunderstorm. This rain, however, seemingly had no effect upon the course and by 11 o'clock this morning it was in fit shape for practice.

There still remains considerable to do before the race on Friday in the way of completing the racing plant. Workmen still are busy putting in the pits in front of the grandstand, but they are putting up permanent repair depots. Instead of making the pits of wood they are cast in con-

1—"Crow's-Nest" on top of the garage at the National camp

3—These huge tents furnished ideal sleeping quarters

5—The National team—Seek, Greiner and Livingstone

7—Where the hungry racers do congregate at mealtime crete so that in future years all that will be necessary in order to make them serviceable will be to dig out the dirt which will fill them during the year. The grandstands were completed yesterday; but this is no trick, for the stands are the same that were used during the Masonic doings here in Chicago. They are easily transported and by using them the Elgin association saved considerable money.

In marked contrast with other road races, the Elgin people have made every effort to down extortion. Rooming accommodations can be had in the town for $1 a day, while the storekeepers have shown they possess civic pride by not shoving up their prices. Another thing that will tend to increase the attendance is the fact that popular prices prevail on the course. There is an initial charge of 50 cents for general admission and after that seats may be had in the bleachers for 50 cents, grandstand seats for $1 and box seats for $1.50. Parking spaces are sold for $1 per car, which fact will surprise many who have been accustomed to pay from $10 to $25 for such a privilege. By catering to the masses in this way it is evident that Elgin will draw crowds that will rival the Vanderbilt in size. These crowds will be handled with great facility by the railroads, which plan to run special trains as often as the people fill them.

The course is located within one mile of the heart of Elgin, so that even if the Elgin trolleys which run to the edge of the course cannot accommodate everyone it will be no great hardship to walk. If there isn't a crowd at the races it will not be the fault of the Chicago papers, which have become so interested in the event that they devoted pages to the races last Sunday and are following up this publicity in a manner which cannot fail to bring the speed carnival to the attention of the general public. Already all of the ninety-two boxes have been sold and many reservations have been made in the grandstand.

The Elgin races will not start at daylight, as will the Vanderbilt, for Westerners have not yet been educated to that point, nor can the roads be tied up so early in the morning. Each day's racing will start at 10 o'clock, and the course will be closed by the soldiers at 9 o'clock.

There was a slight change in officials made to-day, when George E. Hunter, of Elgin, was made honorary referee, in place of C. H. Hulburd, president of the Elgin National Watch Co., whose engagements would not permit him to fill the position. Succeeding Mr. Hunter as judge is Walter Egermann, president of the Aurora Automobile Club which presented the Fox River trophy. M. H. Portmer, of New York, will handle the Warner Electrical Timing apparatus that will be used.

Following is a complete list of entries for the four events:

LIST OF ENTRIES FOR THE ELGIN TOURNAMENT

Car	Entrant	Model	No. Cyl.	Bore	Stroke	Driver
Elgin National Trophy						
1. National	A. W. Greiner	1910	4	5	5 11-16	A. W. Greiner
7. National	National Auto. Co.	1910	4	5	5 11-16	A. Livingstone
10. Marmon	N. & M. Co.	1910	4	4½	5	J. Dawson

The Motor in the Air

CONSPICUOUS EVENTS AMONG AVIATORS DURING THE WEEK —WRIGHT MACHINE FREED FROM FRONT INCUMBRANCE PROVES SUPERIORITY OVER OLD TYPE

At Asbury Park, a summer resort on the New Jersey coast near New York City, an aviation meet was opened August 10 and was still in progress August 23, though at first arranged for ten days only. The opening days were made notable by two accidents. Dropping from a height of 2,000 feet a parachute jumper named Prince, whose apparatus failed him for causes which have been explained but still remain unknown, met immediate death. The aviators at the meet were all employed by the Wright corporation. One of them, Walter Brookins, tried to make a landing by spiral descent to a certain narrowly defined spot and fell from a height of about 100 feet into a crowd of onlookers, several of whom were injured. Brookins escaped with severe contusions of his face, and appeared again later at the meet, undaunted. Maurice Garsuch, 18 years old, whose skull was at first supposed to have been fatally fractured, has since filed suit for $15,000 damages, and George Burnett, who suffered concussion and dislocation of the hip, is reported to be preparing to enter suit for a still larger amount. The machine was smashed beyond repair. No indictment was found. To replace the destroyed machine a large new Wright biplane was sent to the meet from Dayton, Ohio, and arrived on August 15. Its construction and performances soon became the sensation of the meet and of world-wide importance. All that remains in front of the biplane proper in this machine is the fore part of the skids, the front elevating planes or tilt rudders having been abandoned, and the up-and-down direction is controlled solely by means of a rear horizontal single-plane rudder, as in monoplanes and Voisin biplanes. The size of the new machine is figured sufficient for carrying six persons. In its performances on Monday, August 22, it proved itself capable of much greater mobility, in the acrobatic evolutions by which it was tested and exhibited, than the older Wright type, and it flew steadier in the straightaway and faster. Unless a bad-weather test should eventually prove its equilibrium to be beyond the aviator's control, in greater degree than for the older type, it will therefore be extensively imitated, being in itself an adaptation from other aviation machines.

John Moissant, a cavalier of fortune hailing from Chicago, but known in many other parts, started from Paris with a French mechanic as passenger Tuesday evening, 5:45 o'clock, August 16, and flew to Amiens, arriving 7:40; started from Amiens, after a gay night with friends, Wednesday morning, 5:45, reached the Channel at 10:50 a. m., continued across and reached Tilmanstone, six miles beyond Dover, just at noon. He said he had steered by a compass suspended in glycerine and placed between his feet, being unable to see anything by reason of foggy weather. Several attempts to get from Tilmanstone to London between August 18 and August 22 came to naught through troubles with the Gnome motor, which the French mechanic could not sufficiently remedy. On August 22, according to Associated Press dispatches, Moissant and his companions, in making a last attempt to reach London, only twenty miles away, despite a contrary wind estimated at thirty miles per hour velocity, were hurled to the ground, and the machine was much damaged, while the aviators escaped unhurt. Before this flight Moissant is reported to have flown only five times.

On August 17 a 488-mile cross-country contest, which was divided into laps and arranged so as to give the participants great latitude in choosing time and weather, was won by Leblanc driving a Blériot machine. Auburn was second, and Legagneux in a Farman biplane was in at the finish, though disqualified on a technical point. Several army officers also finished the circuit, but were prohibited from competing. The number of contestants from the beginning included many of the best-known French aviators.

On August 20 Clifford B. Harmon, of New York, a well-known real estate dealer and amateur aviator who has been practising flights with Farman and Curtiss biplanes at Mineola, L. I., flew in a Curtiss machine from Hempstead, L. I., over the wooded land surrounding Roslyn, across the Sound to near Mamaroneck, landing close to the country seat of his father-in-law, E. C. Benedict, and won the Doubleday prize for the first who crossed the Sound.

Industrial Aeroplanes

(*Continued from page 302.*)

Further, as it is the air resistance itself which places the resilient blades at their working pitch, the reaction of the blades against this deflection must be of equal force, and, as this reaction is delivered against the atmosphere at exactly the same angle and otherwise exactly the same conditions as those governing the thrust due to rotation (of either the rigid or the resilient propeller), the total thrust of the resilient propeller must be exactly twice (minus friction losses) that of the rigid propeller.

Through a chain of reasoning no less cogent than simple mathematics, it is therefore established that a resilient propeller, in which the resiliency has been properly calculated and materialized to equal the resistance against rotation at a desirable pitch, will consume and deliver twice as much power as the rigid propeller of the same desirable pitch and of the same identical dimensions.

This alone places the properly designed resilient propeller in a separate class.

In order to simplify the reasoning it has been assumed here that all of the resistance against rotation is air resistance and that all the air resistance is utilized to deflect the resilient blades. A different assumption simply makes a stronger case for the resilient propeller, reducing the power consumption to be expected of it while maintaining the thrust it delivers as at least twice that of the rigid propeller. The different assumption does, however, affect the spring resistance which should be employed. It should correspond (with allowance for the leverage employed in overcoming it) not to the total resistance against rotation but to that portion thereof which is utilized to cause the deflection. And this is probably equivalent to the portion which is transformed into propulsive thrust by rigid propeller blades. So, the advantages to be gained by means of resilient construction, once its intricacies shall have been mastered, have been rather understated than overstated.

Further consideration of all the factors involved, for which there is no space in this article, leads one to assume that the resilient propeller will eventually do a good deal more than may now be proved for it in words, and especially that the power which it will consume will be taken in practice not from the motor (so as to necessitate an increase of motor power) but from the waste which occurs when motor power is applied to rotate a rigid propeller. No absolutely compelling argumentation can be offered for this contention, but it is known that the thrust produced by the most improved standard propellers nowise corresponds to the power which produced the thrust, coming scarcely within 20 per cent. thereof, and that nevertheless the slip in these propellers is extremely small and perhaps in some cases even negative, so that their efficiency measured by their slip, as customary for marine propellers, approaches 100 per cent. This situation seems to indicate that the rigid propeller, save for what action of a different order may be due to the transverse curvature of the best rigid blades, simply screws itself through the atmosphere but wastes practically all the thrusting capacity which might be gained by adapting the blades to work by "impulsion" as well as by pressure. The importance of impulsion in steam turbine engines being fairly well understood, it would seem rational to attempt to apply a similar principle to atmospheric propellers which act in a medium no less elastic than steam. Bearing in mind the capacity of the resilient propeller for absorbing and delivering a powerful thrust, twice as powerful a thrust as the rigid propeller of the same dimensions can be made to deliver, it may be rash to assume that the resilient construction constitutes the only means for gaining impulsion and a 100 per cent. increase in power economy, but a certain probability is at least established to the effect that the resilient propeller is capable of a highly important practical development. And it is possible to predict, with only one alternative, one of the results, which is the complete abandonment of slip as a measure for the efficiency of atmospheric propulsion (and in fact marine propulsion as well). This follows logically from doubling the thrust of the rigid propeller with a resilient propeller of identical dimensions. The doubled thrust must produce a speedier forward movement, which means a pronounced negative slip. And a negative slip is an absurdity as a basis for measurement. The alternative prediction is that resilient propeller blades will be found to work most effectively at double the pitch used for rigid ones.

The skids in the described aeroplane machine are intended for use with the practically developed resilient propeller.

Thomas Dealers Convene at Buffalo

Buffalo, Aug. 20—The E. R. Thomas Motor Company's Dealers' Convention closed a three-days' program of business and pleasure with a smoker at German-American Hall this evening. There were speeches made by President E. R. Thomas and other officers, and a vaudeville entertainment was enjoyed by about 90 guests of the company.

Thursday afternoon at 1:30 the dealers took dinner at the factory. After a short business session, they were entertained with a beefsteak supper at the Hotel Lafayette. The dinner was enlivened with bits of comedy contributed by the officers and visitors. This was followed by a theater party.

The business session on Friday morning had for its principal feature an engineering talk by H. G. McComb, chief engineer of the company, dwelling upon the various functions of the chassis and motor, and expatiating upon the new Thomas Flyer.

The afternoon session was taken up with a demonstration of the 1911 models, together with a talk on body construction by A. W. Woodruff.

Mack Wins in Its Class in Truck Roadability Run

The entry of Shave Brothers & Wilson, the Mack, driven by E. Turgeon, has been announced as the tenth winner in the recent roadability run for motor trucks conducted by the Philadelphia *North American* and the Quaker City Motor Club. This was in the class for mammoth trucks (gasoline) above five tons, which was not decided by the contest committee at its meeting last week.

Communications

THE LOGIC OF THE PROPOSITION AS HANDLED BY A MAN FROM NEVADA AND OTHER TERSE COMMUNICATIONS DISCUSSING THE MERITS OF THE AUTOMOBILE FROM AN ECONOMIC POINT OF VIEW

The Logic of the Proposition.—"And there is no new thing under the sun," Ecclesiastes, 1:9. In the words of our text the inspired writer foretold the coming of those prophets of evil, who see peril to our country in the automobile. From the wireless telegraph back to the day when Eve first decided to wear a fig leaf, victims of mental strabismus have shied at every step in the world's progress.

In 1673, just after the introduction of stage coaches, a book entitled, "The Grand Concern of England, etc.," denounced them as among the greatest evils that ever happened to the Kingdom. It alleged that "traveling by coach was calculated to destroy the breed of horses and make men careless of good horsemanship; that it hindered the training of watermen, and seamen, and interfered with the public resources; that those who were accustomed to traveling in coaches became weary and listless when they rode a few miles and unwilling to get on horseback, not being able to endure frost, snow or rain, or to lodge in the fields; that to save their clothes and keep themselves clean and dry, people rode in coaches and thus contracted an idle habit of body; that this was ruinous to trade, for the reason that most gentlemen, before the days of coaches, were wont to ride with swords, belts, pistols, holsters, portmanteaus and hat-cases, which, in the coaches, they have little or no occasion for; for when they rode on horseback they always carried along an extra suit for change at the journey's end or by the way; but in coaches they would ride with a silk suit, an Indian gown with sash, silk stockings, and beaver hat, and carry no other along, because they escaped the wet and dirt which on horseback they could not avoid; whereas, in two or three journeys on horseback these clothes and hats were wont to be spoiled; which done, they were forced to purchase new, and that increased the consumption of manufactures and the employment of the manufacturers, which traveling in coaches doth in no way do."

The logic of the proposition is unanswerable, and the style of reasoning singularly familiar. With slight paraphrasing, it would present, even more convincingly than the most lurid pipe dream, the necessity for aborting the automobile industry.

A friend of mine has just come from Iowa, where he has for many years done business in a large way, and come to know the State and its conditions thoroughly. He tells me that this latest "bugs-in-the-attic" malady is epidemic in that State, and that many of the bankers have it in so virulent a form as to seriously embarrass the farming industry. He further tells me that the increase in actual values in that State within the past ten years, due to the motor vehicle alone, is, on a most conservative estimate, not less than half a billion dollars.

One phase of this subject which I haven't seen referred to is that the present universal, insistent demand for improved highways throughout the length and breadth of this country has come principally because of the motor car. Without it we would not have reached where we are now for the next twenty-five years. As this is a continuous and increasing national asset, it can be measured only as capital, upon which the money value of one year's economic benefit due to the motor vehicle's part of road improvement would be, say, 5 per cent.

Wonder when Ike Partington will give his mother a hunch to cut out the attempt to sweep back the Atlantic Ocean with her broom, and beat it?—James W. Abbott, late special agent U. S. Highway Department, Piocke, Nevada.

A Quandary Which Is Still Quandering—His wife wanted an automobile, just a little one with seats for two and a dog, but he could not quite "see it." There were so many other things he had in mind and knew he would want some time. But now she had finally tucked away $800 out of her own personal savings. It was all in nice clean yellowbacks in a box downtown. The little scoundrel had been knitting fashionable sweaters, while he was at his office, and had sold them regularly to "Francoise," the ladies' outfitter. It was getting hard to resist so much ambition and persistence, hard to tell her about cost of "upkeep" and the valuable time spent in gadding about, interest lost when they did not use "it," garage charges if they stored "it" and insurance troubles if they built a shed for "it" in the backyard. He had taken Tony home with him this evening to stave off argument. Tony was his lawyer friend, a smart, resourceful chap and a nice fellow, though diplomatic to the backbone.

It did not work out as calculated. There is a tide in the affairs of women when a barrier does not stop them, but only invites them to leap. Chauffeuse-to-be appealed direct to Tony. But Tony was prepared and did not need to glance from one to the other. "Yes, it would be nice, of course. What car had you thought of buying?" He said it with the grace that comes so much easier to the proxy than to the principal. Tom looked doubtful. Was Tony going back on him?

"Well, if you have not really made up your minds yet, I should advise you to take an automobile paper for a while," Tony resumed after explanations. "I have a friend who tells me that it is astonishing how much real information seeps out between the lines of one of those papers when you read it regularly for three or four months. They simply cannot hold it back, much as they try." Tom saw the light. Here was at least delay. But after that, what? It might come out worse than ever. She might get the impression that nothing less than a $2,000 car would be worth while.

"Ha, ha, ha, I had you scared, Tom. Don't deny it." Tom was following his friend to the street car line, and they had just turned the corner safely. "What, you old stylite, where have you been these years? Don't you know how that paper game works? They are just for men. There is not a woman who can read one of them without getting disgusted and all mixed up. All you have to do now, Tom, is to get your wife to read it regularly, bless her innocent soul. But look out for yourself, it is apt to work the other way around with you." "I guess you meant all right, Tony," Tom said briefly, "and I suppose I shall have to chance it, but——well, good night, Tony."

The Motor Car Not an Extravagance—It is argued that many people cannot afford to own motor cars. The answer to this argument is that the ownership of a motor car so increases the radius of the owner's activity, and has such a pronounced influence on his efficiency and health, that he is able to earn an income that will enable him to support a motor car. Of course, there are exceptions to prove this rule, just as there are exceptions in all other lines. It can be admitted, without prejudice to the industry, that some persons may have purchased motor cars at a cost and of a type not adapted to their requirements. This does not prove that this class of persons cannot afford to own motor cars. It must not be assumed that just because it is a motor car, that it is an unnecessary expense or extravagance. The use of the motor car does not distract its owner's attention from his business. On the contrary, its use enables him to do more business, with less effort, in the same hours, by shortening the time of his errands and business calls. At the same time it affords opportunity for healthful recreation for himself and family and saves many expenses which were common before its use began.—C. C. Hanch, Treasurer of the Nordyke & Marmon Company.

Award of Trophies in Brooklyn Dealers' Run

A. R. Pardington, referee in the recent two-day reliability contest of the Brooklyn Motor Vehicle Dealers' Association on Long Island, has announced the winners of the eight handsome trophies contested for in the two sections of the contest as follows:

Martin-Evans trophy, division 1A, cars that sell for $800 and under, won by No. 14 Hupmobile, driven by D. M. Bellman.

Brooklyn *Daily Times* trophy, division 2A, cars that sell for $801 to $1,200, won by No. 4 Hudson, driven by W. H. A. Bruns.

Standard Union trophy, division 3A, cars that sell for $1,201 to $1,600, won by No. 26 Crawford, driven by W. J. Houldcroft.

The Julius Bindrim prize, offered as a second trophy in division 3A, was won by No. 8 Maxwell, driven by E. T. Bloxam.

The Kingsley Swan trophy, divisions 4A, 5A, 6A and 7A, for touring cars that sell for $1,601 and over, won by No. 21 Columbia. driven by G. M. Wagner.

The Brooklyn *Life* trophy, competed for in divisions 4A, 5A, 6A and 7A, open for runabouts that sell for $1,601 and over, won by I. C. Kirkman, who drove No. 1 Columbia car.

In the tourist section the most consistent running time was made by the Ford, No. 50, to which is awarded the Brooklyn *Daily Eagle* trophy.

The next best running time in the tourist division was made by No. 52 Cadillac, driven by H. G. Woodworth, who wins the Long Island Automobile Club trophy.

Auto Mail Delivery Efficiency Test

PHILADELPHIA, Aug. 22—The first United States mail automobile efficiency trial, to be held under the auspices of the Quaker City Motor Club, will take place during the week of August 29 to September 3. Each day two cars will start from a point selected by the post office authorities, the object being to reduce the time of delivering the early morning mail. The time en route is to be strictly noted and the car finishing delivery in the quickest time will be awarded a sterling silver trophy. So far the following entries have been received:

Louis J. Bergdoll Motor Car Company, Bergdoll, August 29; Oxford Automobile Company, Brush car, August 29; Philadelphia K. M. F. Company, Hudson car, August 30; Olds-Oakland Company, Oakland, August 30; W. J. Sprankle, Overland, August 31; Harvey Ringler, Chalmers-Detroit, August 31; H. C. K. Motor Car Company, Kline-Kar, September 1; Longstreth Motor Car Company, Pullman, September 1; Prescott-Adamson, Reo, September 2; Continental Motor Car Company, Parry, September 2; Penn Motor Car Company, Mitchell, September 3; Johnson Motor Car Company, Al La Roche, September 3.

Catskill Reliability Run and Hill Climb

Entry blanks are out for the two-day Catskill Reliability Contest and Hill Climb September 10 and 12. The tour will start from New York on Saturday morning, September 10, at 7:30 o'clock, but the cars will not check out until assembled in line at Edgewater, N. J. The tourists will rest on Sunday in the Catskills and on Monday the hill climb will take place on Kaaterskill Clove. A fine program has been arranged for the hill climb. The classification will be by price and piston displacement in cubic inches. The events are as follows:

No. 1—Gasoline stock cars, $800 or under.
No. 2—Gasoline stock cars, $801 to $1,200.
No. 3—Gasoline stock cars, $1,201 to $1,600.
No. 4—Gasoline stock cars, $1,601 to $2,000.
No. 5—Gasoline stock cars, $2,001 to $3,000.
No. 6—Gasoline stock cars, $3,001 to $4,000.
No. 7—Gasoline stock cars, $4,001 and over.
No. 8—Open to amateurs. Limited to cars owned by residents of Catskill and a radius of fifteen miles from Kaaterskill Clove Mountain. Handicap according to price.
No. 9—Gasoline stock chassis between 161 to 300 cubic inches piston displacement.
No. 10—Gasoline stock chassis between 301 to 450 cubic inches piston displacement.
No. 11—Gasoline stock chassis between 451 to 500 cubic inches piston displacement.

Society of Automobile Engineers Growing Rapidly

The following members and associates of the Society of Automobile Engineers were elected this week: Frederick W. Blanchard, Faulkner-Blanchard Motor Car Co., Detroit, Michigan; Henry L. Barton, Metal Products Company, Detroit, Michigan; Edward W. Curtis, Jr., Studebaker Bros. Mfg. Company, Chicago, Ill.; DeWitt Clinton Cookingham, Rauch & Lang Company, Cleveland, Ohio; Geo. W. Cooke, Pierce-Arrow Motor Car Company, Buffalo, New York; T. P. Chase, Chalmers Motor Company, Detroit, Michigan; Wm. Morris Davis, E. R. Thomas Motor Company, Buffalo, New York; Edward Dixon, Thos. B. Jeffery & Co., Kenosha, Wisconsin; Frank E. Ferris, Brush Runabout Company, Detroit, Michigan; H. W. Gillett, Aluminum Castings Company, Detroit, Michigan; Starling Henry Humphrey, Brush Runabout Company, Detroit, Michigan; Geo. N. Hickey, Van Dyke Motor Car Company, Detroit, Michigan; Wm. H. Hogle, Brush Runabout Company, Detroit, Michigan; Harold H. Kennedy, The Waverley Company, Indianapolis, Indiana; Fritz Loeffler, Mannheim, Waldorf, Germany; Ralph L. Morgan, Ralph L. Morgan Company, Worcester, Mass.; Horace Henley Newson, McCord Manufacturing Company, Detroit, Michigan; George L. Norris, American Vanadium Company, Pittsburg, Pa.; Chas. B. Rose, Velie Motor Vehicle Company, Moline, Ill.; Wm. H. Reddig, Chalmers Motor Company, Detroit, Michigan; Charles R. Short, G. & E. Power Company, Philadelphia, Pa.; Nicholas Shamroy, Landau & Golden Company, New York City; Clyde W. Stringer, Brush Runabout Company, Detroit, Michigan; Geo. A. Weidely, Premier Motor Mfg. Company, Indianapolis, Indiana; Frank E. Couch, 316 Hudson Street, New York City; Charles F. Case, Oliver Motor Car Company, Detroit, Michigan; Clyde E. Dickey, Denman & Davis, New York City; Wellington F. Evans, Metal Products Company, Detroit, Michigan; Henry May, Pierce-Arrow Motor Car Company, Buffalo, New York; George S. Morrow, Stepney Spare Wheel Company, Chicago, Ill.; Albert F. Rockwell, New Departure Mfg. Company, Bristol, Conn.; Winfield DeWitt Rheutan, The White Company, Cleveland, Ohio; R. A. Radle, Clark Sales Company, Detroit, Michigan; Thomas Towne, Ideal Opening Die Company, New York City; Walter Webster Totman, Whitney Mfg. Company, Hartford, Conn.

Westerners Contemplating Secession from A. A. A.

SEATTLE, WASH., Aug. 22—Convinced that the West, and particularly the Pacific Coast, will never derive any benefit from either the A. A. A. or the A. C. A., Frank M. Fretwell, a prominent member of the Automobile Club of Seattle, and Clifford Harrison, assistant secretary of the Portland Automobile Club, have issued a call for a meeting to be held in Seattle, September 4th, to discuss plans for the formation of a Western Automobile Association. The plan embraces every club in Washington, Oregon, California and British Columbia.

At that time the Portland, Ore., and Vancouver, B. C., clubs will attend in a body as guests of the Seattle Automobile Club. The delegates attending the meeting will be asked to bring a certified statement of the membership of the club they represent, as the voting will be on the basis of the club membership.

It is also Harrison's idea to publish a substantial periodical in connection with the association and to make the annual dues large enough to cover the cost of sending copies to each member, the book to be similar to the one published by the A. A. A.

George S. Patterson to Be President

Having resigned his position as general manager of the Gaeth Automobile Company, of Cleveland, Ohio, George S. Patterson is now in the East on a mission of more than the usual importance. It is whispered about that he is to be the president of one of the important companies and that he is on a "still hunt" for men and material with which to put the finishing touches on his already successful career in the automobile field.

Perfect Scores in Munsey

(*Continued from page 297.*)

of Rhode Island and those of Southern Connecticut. They remained in practically the same condition as he left them until within the past ten years, when the coming of the automobile gave road building a decided impetus.

From New London to Westerly there could be considerable improvement, but from that point to Narragansett Pier and from the Pier for 25 miles toward Providence, the roads leave nothing to be desired. The route to Boston was over the chief line of communication between the earliest colonies in New England. Governor Winthrop laid out most of the roads, and traces of ancient earthworks erected by him to protect the road during Indian troubles are still visible.

Historically the roads were interesting. Leaving the Thames, the way led past the school house in which Captain Nathan Hale taught when he received the call to arms that meant shameful death and immortal fame for him. Fort Griswold, that ill-fated stronghold that was overwhelmed by a British force, next attracted attention. The story of Colonel Ledyard's foul murder and the massacre of the handful of defenders of the fort were remembered while the cars whirled by.

The end of the day's run at Boston, with all the thrilling memories of that city, was an enthusiastic finale to a day of mixed feelings. The city of Providence was generally censured for the position assumed by the authorities against the tourists and not a voice was raised in behalf of the action.

One of the features of the night stop at New London was an informal reception at the exclusive Thames Club, at which Mr. Doolittle, of the editorial staff of THE AUTOMOBILE, was a guest of honor. After being presented to all present Mr. Doolittle was asked to speak, and in a somewhat detailed address he treated of the mission of the motor, particularly applied to conditions in the State of Connecticut, pointing out the vast increase in real estate valuation that has resulted by reason of the effect of the automobile in making great tracts of barren land valuable for the bungalow sites of rich men living in New York and other centres of business. He also outlined the purpose of the Munsey Historic Tour.

Fourth Day

PORTLAND, ME., Aug. 19—In a driving rainstorm the Munsey tourists started the fourth day of the run from in front of the Hotel Lenox. Boston is a difficult place to get out of, and several of the cars managed to get lost before reaching the city limits. The first few miles were through territory rich in historic incident. The place from which Paul Revere started his famous ride; the scene of the glorious defeat of Bunker Hill and a dozen other events treasured in the history of the nation, were passed in getting started on the great Atlantic Boulevard leading to Portland. This road was built early in the last century as an outlet for the rum and sugar manufactured at the Maine metropolis from the cane syrup and molasses imported in the holds of the numerous ships that plied between that port and the West Indies. Naturally there was other freight to be moved over it, as the country developed, and at one time the travel from Boston, and even farther south and west, was comparatively heavy. But in the interim that followed the decay of the rum and sugar trade, and before the fish industry of this section became a commanding factor, the road fell into disuse to a large extent and only within the last few years has it been rehabilitated. In places it is about as fine as anything so far traversed by the tourists, but in others the work of straightening, smoothing and hardening is still in the early progressive stage.

Maine is taking a vast interest in State roads, and in no fewer than four spots of to-day's route the caravan passed road-making gangs. In New Hampshire the highways were in uniformly good condition. One of the pleasant things about the run through Massachusetts was the hearty reception accorded the travelers at Gloucester, Mass., the ancient seaport, whose ships once sailed on each of the seven seas. Gloucester is not resting on the memory of a glorious past. It is a lively little place and its citizens realize the commercial importance of the automobile even better than several of the avowed centers of motoring. When the tour passed through to-day, the Board of Trade of Gloucester was on hand with a welcome that prejudiced every member of the touring column in favor of the city. Interesting booklets descriptive of the city, its past, present and possible future, were given to everybody in the procession with a hearty expression of good-will toward the automobile.

Beverly, the summer home of President Taft, was another object of curiosity to the caravan.

In Maine the route followed the coast practically all the way to this city, and at the numerous summer resorts big crowds of pretty girls cheered the progress of the tour. No conflict with the authorities was reported to-day, which was a welcome change from the Rhode Island experience.

The Staver-Chicago, No. 23, was the only car that lost its chance to secure a perfect score as a result of the day's run. This car damaged a bearing in the differential on Wednesday, but was not so seriously hurt as to be put out of the running on account of that mishap. But when the car had proceeded two and a half hours out of Boston one of the rear springs gave way and it required 2 hours and 27 minutes of repair work before the car could move on. This caused the Staver-Chicago to be 42 minutes late at noon control and the total penalty assessed by the technical committee was 169 points.

The Inter-State also earned some additional penalties, as some more loose metal, including a bit of phosphor bronze, turned up in the gear case. Mr. Dill decided to accept the penalization now, rather than to wait until later in the run, when he might get much more, and after a thorough examination of the transmission, which occupied 62 minutes, he announced that the car was again in good shape. The penalty imposed to-day was 62 points, making the total against the Inter-State 111.

The score stands at the end of the day with 21 cars still in the list of perfect records.

Fifth Day

BETHLEHEM, N. H., Aug. 20—Across the State of Maine and half way through New Hampshire was the course of the fifth day's running of the Munsey Tour. The roads were smooth enough practically all the way, but the grades and turns proved too much for several of the cars and accomplished the complete downfall of one of them.

It was the Maxwell runabout that succumbed just after passing through Crawford's Notch and with nothing like a real obstacle between the car and the night control. The camshaft broke on the exhaust side, stripping the gears and messing up the mechanism of the car so that it was withdrawn from competition, the penalty assessed being 1,000 points.

The Elmore, privately owned, also met with its first set-back during the day. A broken terminal in the ignition required three minutes' work to fix, and the motor was stopped during that time. The net result was 6 demerits.

The Staver-Chicago suffered further penalty when the upper half of the left rear spring gave way. The penalty was fixed at 73 points.

The Moon car also added a single point to its score, when the jarring and swinging necessary to make 20 miles an hour rendered one minute's repair work necessary on the rear fender. This gives the Moon a total of 2 points.

One of the Fords is in trouble with a loose motor base. The Columbia and Pierce-Racine still have clean scores, despite loose connecting rods in one and ignition trouble in the other.

The wounded Maxwell car was towed away to the Mount Washington garage by the Brush Runabout, used as the photographer's car. All the cars not specially mentioned are apparently in as good condition as when they started.

The Thomas Press car that met with mishap near West Point last Tuesday was repaired by driver George Miller and was rushed over the course to join the caravan at Boston. This the Thomas was able to do, and has been in a prominent position in the line ever since.

The tour proved to be particularly popular in Maine, and clear to the Western boundary, wherever there was a hamlet, crowds gathered to cheer the procession.

The course in New Hampshire, through the heart of the Bretton Woods and the White Mountains, was by far the most picturesque of any so far. The level of the highway rises constantly from the State boundary until the course lies between solemn-looking cliffs, clad in summer verdure and rising precipitously from the road, which is fully 2,000 feet above the level of Casco Bay at its highest point. The way passes through what is called Crowford's Notch, a gash in the mountain, which has been cut down materially so as to make a passable wagon trail.

From the Notch to Bethlehem the roads were excellent, and the 27 cars left in the contest had no difficulty in reaching control within the time limit.

When the city of Portland was the main seaport for this part of the United States and a large part of Quebec, the traffic toward the seaboard and back again was conducted over the old international highway. Long before that road occupied its present direction and position it was one of the most heavily-used highways in this part of the country. When it was first laid out to Quebec from Portland it made a wide detour, skirting the southern foothills of the White Mountains. As far back as 1772 a hunter, Thomas Nash by name, discovered a pass through the mountains that he reported as available to shorten the road distance to Canada. The story, as told to-day, is that Nash, while out hunting near Mount Washington, then an unnamed peak in the wilderness, lost his bearings, and in trying to discover some peak that was known to him, he climbed a tree, and in that elevated position saw that there existed a narrow gorge between two of the giant hills.

The outbreak of the war for independence caused Nash to forget his discovery for the time being, but after peace had been restored he made a formal presentation of the facts to the State government and received an offer of a large land grant if he could demonstrate the feasibility of the route by leading a horse through the Notch. In 1803 Nash made the attempt and succeeded in getting through. Just how much land was given him as a result of his boldness is debatable, but descendants of the Nash family in the vicinity are accounted among the most prosperous of the local citizenship.

The result of finding the pass in the hills was to cut off at least 100 miles from the former route, and inasmuch as it facilitated trade, it was recognized as a good work even in that early day. To-day the road that follows the course laid out by the hunter is as nearly a perfect specimen of what a mountain road should be as can be imagined.

While the inland wagon trade of Portland has dwindled to nothing and the road is no longer used to bring in freight to be shipped in American vessels, it is of wide importance. For local traffic it is remarkably adequate, and as an automobile highway it answers its purpose admirably.

Sixth Day

Burlington, Vt., Aug. 22—The State of Vermont appreciates the automobile. From one side of Vermont to the other, the heartiest greetings of the tour were extended to the Munsey tourists to-day. No cross-roads were too significant and no city too large to welcome the travelers and the route of the sixth day of the tour, from Bethlehem to the shores of Lake Champlain, was the scene of a continuous ovation.

Vermont is well justified in her favorable position toward the motor car for to that expression of development the whole transverse road system of the State is undoubtedly due.

It was automobile day at Montpelier and the capital was decked out in bunting when the head of the caravan pushed itself over the last hill and entered the city. The business houses closed at noon in honor of the tour and the Automobile Club of Vermont, one of the most active State organizations of its size in the country, arranged for its annual parade through the streets of the capital to take place while the Munseyites were in midday control.

At Montpelier the tour was welcomed by the Governor and other dignitaries and the Automobile Club of Vermont held open house in half a dozen places. After the parade of local automobiles, the run of the afternoon to Burlington was commenced and night control was reached at about 4 o'clock.

The first real mixup of the tour occurred at Burlington. The day's run for Tuesday had been scheduled at 202 miles, but it was found that the time required to ferry over all the cars to Chazy, at the northern end of Lake Champlain, would require over six hours and that boats were not available to do the work at night. Therefore, Referee Ferguson decided to have the cars ferried to Plattsburg and to start the run from that place, making the road distance 137 miles for the day. After preliminary arrangements had been made to do this it was found that only fifteen cars could cross during the night and these were ferried over, the rest being obliged to wait until morning.

Great Western car No. 18 was badly wrecked this afternoon not far from Burlington. The cause of the accident was a careless pedestrian, a woman who stood idly in the path of the car and made no effort to escape, forcing the driver to swing out suddenly. The place was just at the entrance to a covered bridge and there was not sufficient room for the car to pass. It struck the abutment of the bridge and wrapped its front wheels and axle about the timbers. Washington car No. 5 also had some hard luck.

Five miles out of Bethlehem, it was discovered that the radiator was dry and water had to be taken on. Mr. Carter explained to the referee that the car had been filled up in control but that probably some mischievous or careless person had turned the cock and let the water escape. As the car did not leak after being filled, this view of the case was officially accepted and no penalty was imposed.

The Crawford, No. 27, lost its perfect score when it burned out a main bearing on its shaft somewhere east of Montpelier and was late at noon control by 435 minutes. For the resulting trouble to transmission and rear axle, a technical penalty of 432 points was also given. The car was able to join the procession again, and is apparently working smoothly.

The Ford 30 was given eight demerits for work on a loose strut rod bracket, thus taking the car out of the clean score class.

The wrecked Great Western was drawn to a nearby blacksmith shop and the smith labored over it until late in the night. He practically made a new wheel, straightened the bent axle and it was reported that the car would check out to-morrow.

Seventh Day

Saratoga, Aug. 23—The route to-day was materially shortened by shipping the cars across the lake to Plattsburg and starting the run from Bluff Point instead of going clear up to Chazy. It was found that to follow the originally planned route would require ferrying the cars a longer distance in smaller steamers and that it would take at least six hours to do so. Therefore, part of the cars were shipped across the Lake last night and the remainder this morning. The start was made at 11 o'clock, and the run through the Adirondacks, touching Elizabethtown and finishing at Saratoga, was uneventful. The Glide car came to grief during the morning run. This car reported by telegraph that it would withdraw on account of trouble with a main bearing, and loosened connecting rods.

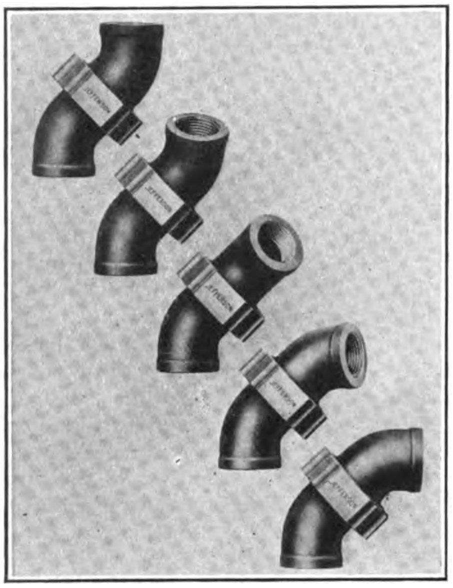
The Elmore is also out of commission because of the failure of the factory to file a stock-car certificate. The entry of the car was made subject to such action by the manufacturers. It is continuing as a non-contestant.

The penalty on the Great Western has not yet been fixed.

Prominent Automobile Accessories

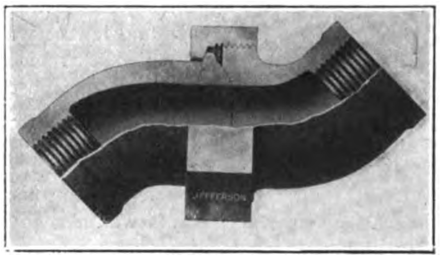
A NEW SWING PIPE UNION

In the accompanying illustration is shown the new swing union which is being made by the Jefferson Union Co., of Lexington, Mass. It consists of two 45° elbow parts with a spherical iron-to-iron seat ground to a perfect fit, the two ends being connected by a nut of either brass or malleable iron. At slightly additional cost these unions can be made with the company's regular brass-to-iron seat, which consists of a narrow brass ring of wrought metal sunk in a channel in which it fits tightly. A lip of iron protects the brass ring from contact with the fluid, and also from injury, should the pipe be screwed in too far. For close work this union can be equipped with a special notched nut which can be set up with a bar of iron and a hammer.



Showing Jefferson Swing Union in various positions

One of the pictures shows the union in various positions from that in which it will connect parallel pipes slightly off-set to the other extreme of connecting two pipes in the same plane at 90°. In the intermediate positions it is possible to make connections between pipes at a great variety of angles, the joint always being perfectly tight regardless of the angle of connection due to the perfectly ground spherical seat. By using the combination of one end of the swing union in connection with regular parts, it is applicable to so many kinds of odd connections that it may almost be considered a universal union.

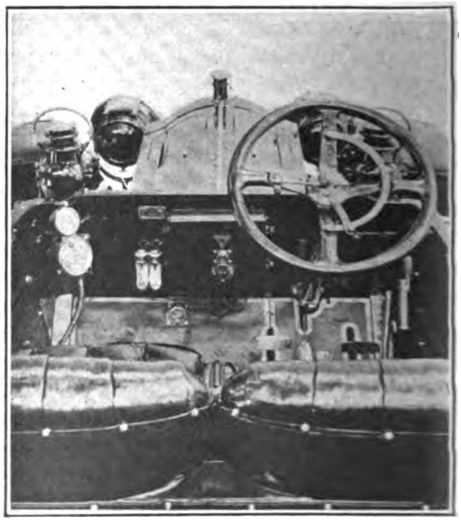


Sectional view of Jefferson Swing Union

SPEEDOMETER AT LEFT SIDE OF DASH

It has been demonstrated that the left side of the dash is a good place for the speedometer, and the Packard Motor Car Company has arranged to attach them on that side of its 1911 models if desired. The accompanying illustration shows the speedometer in that position, which permits of an easy reading of the instrument by both the driver and the occupant of the left front seat. When the speedometer is on the right side the passenger on the left seat cannot see it at all, and often it is difficult for the driver to see through the spokes of the steering wheel when driving at speed.

The left side position also saves the driver from answering the questions of the curious and the nervous. Any speedometer may be attached in this position, because the different speedometer manufacturers are prepared to supply instruments driven from the left front wheel.



Speedometer at left side of dash

THE LARGEST TIRE IN THE WORLD

There is shown herewith an exact reproduction of the famous Morgan & Wright Nobby Tread Tire, which was used for display purposes during the recent Elks' convention at Detroit. According to standard tire sizes, it would be a 96 x 12-inch tire. It is so large that a man can stand upright comfortably inside the rim.

The largest tire in the world

SPECIAL TIRES FOR AEROPLANES

The Diamond Rubber Company, of Akron, O., is in the market with a special aeroplane tire. The tire shown here with a tread of chrome leather has aroused considerable interest among aviators.

Leather-tread tire for aeroplanes

Most types of aeroplanes use from two to four rubber-tired wheels for running along the ground in starting and also for stopping. In the latter case a spoon brake like the old bicycle type, braking directly on the tire itself, is used. On all rubber tires the action of the brake is somewhat destructive to the tread. It is for the purpose of obviating the wear of the spoon brake that this aeroplane tire is made with the tread of chrome leather. It is of the single tube type.

VOL. XXIII NEW YORK—THURSDAY, SEPTEMBER 1, 1910—CHICAGO No. 9

THE AUTOMOBILE

MUNSEY TOUR FINISHED

COVERED with the dust of ten States through which they had passed, the contesting column of automobiles in the Munsey Historic Tour of 1910 that started from Philadelphia, August 16, paraded through the streets of Washington, D. C., late Saturday afternoon, escorted by nearly 100 flag-decked and spotless machines belonging in the capital city. There were two absentees, the Glide entry, which could not be repaired in time to reach Washington on account of the distance from which the spare parts had to be shipped, and the Elmore.

The K-R-I-T, Maxwell runabout and Regal cars, which withdrew at various places along the route and continued as non-contestants, were all in line and running smoothly. The Elmore, owned and entered by Frank Hardart of

Great Western waiting for the brake test

Brush made a brave showing despite tire trouble

Philadelphia, which was disqualified by reason of the failure of the factory management to file its stock certificate covering the car, broke a spring near Harrisburg and could not finish. The Great Western, Crawford and Staver-Chicago, which were heavily penalized on the road, finished the tour with a fine showing of power and running quality.

The two contesting Brush runabouts, three Fords, Warren-Detroit, Maxwell touring car, Moon, two Washingtons, Pierce-Racine, Enger, Ohio, Inter-State, Columbia, Corbin, Cino, Stoddard-Dayton, Kline-Kar and Matheson, seven of which had earned some sort of a penalty, constituted the main division of the tour and were given ovations all along the line.

The official cars were also accorded their full share of the honors. The diminutive Brush runabout, which carried the official photographer and which unofficially came through with a clean road and mechanical score; the powerful Selden, which carried confetti from one end of the route to the other without skip of any kind, under the guidance of J. D. Murphy; the two E-M-F's, which acted respectively as pilot and press cars and which monopolized all the real accidents of the tour outside of the mishap to the Great Western; the starter's car, an Ohio, which had better luck on the road than its team mate in the contesting division, having a spotless record; the Washington car, which carried part of the press representatives and which was driven by Jack Welsh without even a semblance of tire trouble; Referee Ferguson's carriage, a Columbia, which made the run without unofficial penalization, and the giant Thomas Flyer, guided by the hand of George R. Miller, the same engineer who steered the three-ton machine when it won the famous race from New York to Paris, were all repeatedly cheered on the way to their resting place in the official garage.

At the finish of the road work thirteen cars had perfect scores, according to final announcement. These were: Columbia, two Washingtons, two Fords, Corbin, Brush, Enger, Cino, Stoddard-Dayton, Maxwell, Kline and Matheson.

Four cars were penalized for the last day's work as follows: Warren-Detroit, 11 points for work on stay rod and magneto, bringing its total to 15 points. Great Western, 66 points for lateness at noon control and work in repairing a spring, a total of 2,229 points. The Ohio, 3 points for work on a rod, giving this car a total of 79 points. The Moon also earned one more demerit for motor stop, making its total 3 points for its work on the road.

At the conclusion of the run the cars were turned over to the technical committee for a most searching examination. It was estimated that it would require an average of 45 minutes' work on each car to determine its exact condition as compared with its shape when commencing the tour.

The Regal entry's trouble was a broken spring, the accident happening near Bloomsbury. The repair work was accomplished so quickly that much regret was expressed that the car did not continue in the contesting division, as the penalization would have been much lighter than the 1,000 points charged for its withdrawal.

The technical committee, consisting of E. L. Ferguson, James Hemstreet and Joseph Tracy, went to work immediately on the cars and following the spirit that has actuated the officials since the beginning of the run, they announced that the final standing would be ready for publication on Tuesday.

It was a delightful affair from start to finish. Referee Ferguson was on the job every minute, formulating his rulings with refreshing promptness and keeping up to the minute with his tabulations. As a general thing, the score for each day's run was formed and posted ten minutes after the last car arrived, if it arrived within its schedule. If a contestant was late, Mr. Ferguson usually knew why long before the car arrived, and consequently there were none of the exasperating delays that have marked the administration of other tours. Arthur Newmeyer, starter; Mr. Hemstreet of the technical committee, and Francis J. Byrne, the official press representative, are deserving of special commendation for their work, as is also T. C. Willis, the advance man who was belabored at times by all hands, but who performed his duties in a peculiarly effective and efficient manner, arranging for the entertainment of the party along the route. Everybody else who had any official connection with the party did his duty conscientiously and well.

There was no real kicking. Occasionally when a penalty was imposed the sufferer muttered a few things, but in a short time he realized that a tour of this kind is a battle and the unfortunates who fall because they choose to do a gallant deed or through accident where the other fellow is to blame, are just as dead as those who are shot down for running away.

There was a spirit of do or die that characterized the driving of all the cars. Not that it was reckless or foolhardy, but each driver seemed to have resolved upon setting out that he would take his car through without penalty if possible—but he would take her through.

Speaking of the drivers of the contesting cars, the following incident was amusing and illuminative. When the cars drew into Bethlehem, N. H., and the tired drivers and crews alighted and were being assigned to rooms in the Sinclair House, a New York butter and egg operator who is said to be close to the front in that line edged up to the representative of THE AUTOMOBILE and said:

"I see a dozen fellows among those drivers who have exceptional faces; clean-cut brows and firm chins. They show in their appearance that they have the possibilities of taking and holding much higher positions than the mere driving of automobiles. I should say that all of those men there (indicating a group of the drivers) might become first-rate butter and egg salesmen if they showed a willingness to work hard."

The men included in the group pointed out by the butter and egg man were: A. G. Carter, of the Carter Motor Car Company, who had three machines in the tour; Leo Shaab, president of the L. H. Shaab Auto Distributing Company of Baltimore; I. W. Dill, of the Inter-State Automobile Company of Harrisburg; W. S. Mercer, a director of the Great Western Automobile Company of Peru, Ind., and Charles E. Miller, of Charles E. Miller & Brother.

Each of the gentlemen mentioned probably could school himself to sell butter and eggs successfully if he found that selling and making of automobiles was not so profitable as the other line of industry.

All of which shows that keen observation and the ability to pick out real successful men is not lacking among the Summer visitors.

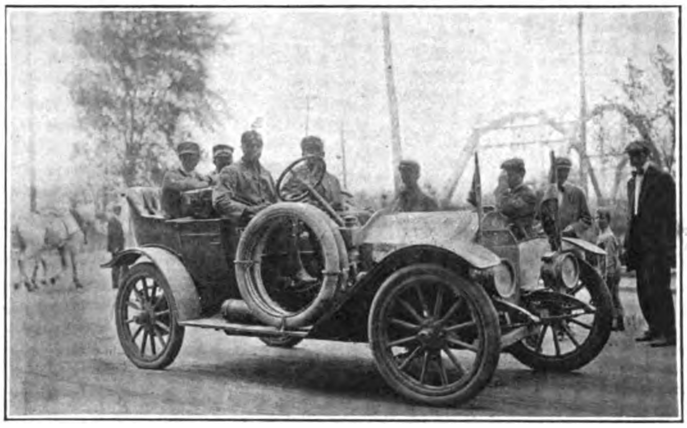
After the technical committee had finished its searching labors at the official garage in Washington, which continued over three days, not a single clean score remained among the contesting division of the Munsey Tour.

Not that the cars were wrecked by their long journey, for most of them could negotiate the route again without radical repairs, but it is hardly in reason to suppose that any automobile could go through such a test as was propounded to the cars of this tour without loosening bolts, sagging springs and other minor and unavoidable troubles.

The Maxwell touring car, No. 25, with a clean road score and penalized 3 points on final technical examination for the loss of a fan belt, was the winner of the sweepstakes prize. The car was driven with masterly skill and care throughout the contest and did not show a semblance of trouble until the committee got to work.

The winners in the various classes were: Brush 14, which had a perfect score on the road, but which was penalized 26 points by the committee; Ford 34, with a perfect road score and a technical penalty of 7 points; the Maxwell touring car as noted; the Washington roadster No. 6, which was penalized 12 points in the brake test and 8 points on final technical examination; the Stoddard-Dayton, No. 24, with a clean road score and a final penalty of 12 points and the Matheson 32, which was penalized 102 points on the brake test and 20 points on final technical.

Among the non-winners Brush 13, Ford 8 and Ford 30, Warren-



Staver-Chicago at Wilkes-Barre

Pierce-Racine going up one of the hills at Wilkes-Barre

Detroit 10, Washington 5, Enger 17, Corbin 11, Columbia 2. Cino 22, and Kline 31, only missed their classes by narrow margins.

No clutch, transmission nor motor trouble was discovered in any of the contestants by the technical committee, a remarkable showing. Several of the highly penalized cars deserve special mention. This is particularly true of Great Western 18 which was wrecked outside of noon control near Montpelier, Vt. La Mar, the driver of the car, was approaching an iron bridge when a woman suddenly turned into his course. Two paths lay open to him. He could either take a chance of injuring the woman or he could shoot his car into the iron girders and supports of the bridge. Like a good sportsman he chose the latter course and as a result his car was wrecked.

With his front axle in the shape of a letter S and with one wheel in fragments, the driver set to work to make repairs. A country blacksmith worked with the crew until after midnight and amid the cheers of those who knew the true facts in the case, the car joined the procession at the next control and finished the trip. Its penalty was 2284 demerits.

The Regal, which broke a spring in the last stages of the tour, had an unsmirched record up to that unfortunate moment. The unspeakable chuck-holes of the Pennsylvania highways were the cause. Why in the ordinary course of human events anybody should wish ever to ride over such roads in a motor car is inexplicable. The wonder is not that the Regal broke a spring, but that the more fortunate contestants did not do so.

FINAL SCORES OF CONTESTANTS IN MUNSEY RUN

		Final Examination					
No. Car	Road Pen.	Brakes	Clutch	Trans.	Motor	Fin. Technic	Total
Division 1A—$800 and under

28—Glide	1000—withdrawn as contestant						
Division 6A—From $3,001 to $4,000							
33—Matheson	0	102	0	0	0	20	122

The K-R-I-T and Maxwell runabout, which were withdrawn on account of mishaps, one on account of a broken wheel and the other as the result of a broken bearing which caused a lot of trouble, finished the tour with a dash that belied the fact that they were declared out of the contest.

The Inter-State entry suffered the worst luck of the tour. But for the presence of a handfull of scrap metal in its gear case at the outset of the journey, the record of this car proves that it would have been tied with the winner of its class for the cup and the chances are that the difficulty experienced by this car at the start may have had some effect upon the brake and final technical penalties imposed. Of course, an entry in a great contest should be inspected with exceeding care before the flag falls, but the entrants of the car were generally accorded warm sympathy for the strange mishap that cost them a more prominent place in the final result.

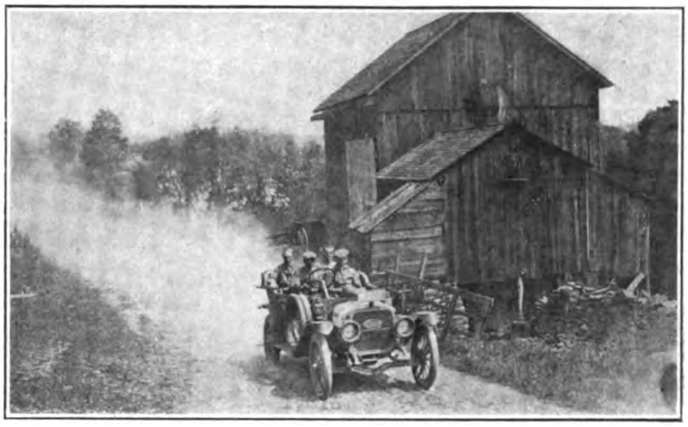
The Moon, Staver-Chicago and Crawford entries received considerable penalties of one kind and another, the Moon breaking a spring leaf, the Staver experiencing trouble with a bearing and the Crawford having similar but more serious trouble. All three finished in style despite the vicious Pennsylvania and Maryland roads.

The Matheson had real tough luck. The car had run along with perfect score until turning for home, when, after following the pacemaker and starter on a wrong trail which led to a hillside road covered with rolling gravel, there was some error in signaling and the Matheson, when within three car lengths of the official cars, was forced to put on brakes. The rolling gravel would not hold the car and despite everything that could be done the car struck the Ohio roadster occupied by the starter and

Stoddard-Dayton scampered along the road at Wilkes-Barre

Selden leading across the bridge at the Susquehanna

sprung a spindle and bent a side member. While its score on the road was clean, the brake test showed what had happened.



Corbin, just beyond Saratoga, on the State road

WASHINGTON, D. C., Aug. 27.—The last day of the long grind was in some ways the hardest of the tour. The Pennsylvania roads to Gettysburg were rough in spots, and the long fine drive over Confederate avenue, where the Army of Northern Virginia was stationed during the great battle of the Civil War, came as a welcome relief after the terrific jolting the cars received between the starting point at Harrisburg and the battlefield. Pennsylvania has more than an abundance of road-making material at hand, and the condition of the roads is inexplicable save on the hypothesis of neglect.

After crossing into Maryland, a very different story is to be told. Going into Frederick, for miles the roads are conducted as toll-roads. Where they are not criminally neglected, they are so filled with big water breaks that riding with any comfort, at a greater speed than ten miles an hour, is preposterous. It takes a lot of nerve to charge real money for the privilege of riding over such disgraceful highways, but the word was passed around that running a toll-gate in Maryland was practically a capital offense, and the keepers of the gates added to the impression.

Honors Divided at Elgin

LOZIER WINS THE ELGIN TROPHY, NATIONAL CAPTURES THE ILLINOIS, MARMON ANNEXES THE KANE COUNTY AND THE BENZ THE FOX RIVER TROPHY

ELGIN, ILL., Aug. 27—Under the auspices of the Chicago Motor Club, the most ambitious programme of long-distance road racing events ever promoted in this country was brought to a successful conclusion to-day when the Lozier, driven by Ralph Mulford, swept over the line a winner in the big event of the carnival—the Elgin trophy race.

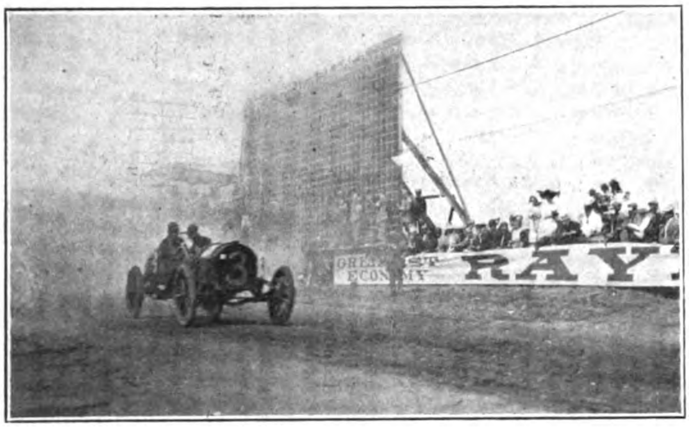
Yesterday saw the National, driven by Livingstone, win out in the Illinois trophy race; the Marmon, with Buck at the wheel, capture the Kane County trophy, and the Benz, with Hearne up, lead the field to the wire in the race for the Fox River cup.

The victory of the four-cylinder 1911 Lozier to-day was from as brilliant a field as ever faced the starter in an American stock chassis road race. The average pace maintained was within a fraction of that made by the Alco in the last Vanderbilt, the rating being 62.5 miles per hour for 305 miles, whereas the Alco did 62.8 for 276 miles in the Vanderbilt. As in the case of the National in the Illinois and the Benz in the Fox River, the Lozier went the entire distance without a tire change. But one stop was made, and that to take on supplies at 203 miles.

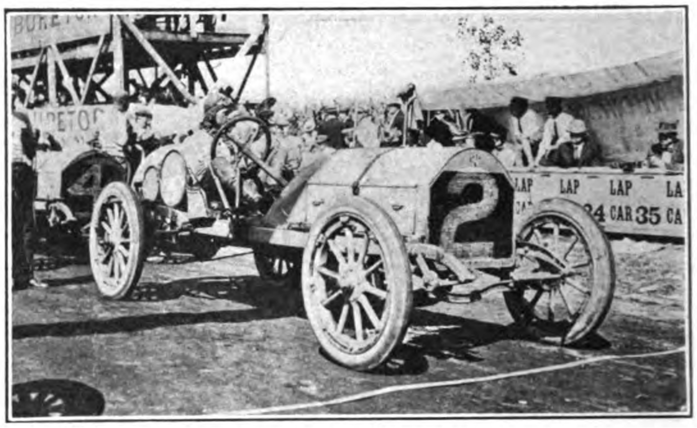
The big white Lozier with its white-garbed driver and mechanic made a great impression upon the 75,000 spectators by the steadiness of its running. With the regularity of an express train and at a speed fully as great, lap after lap was made with great consistency. The fastest circuit was the twenty-second, in 7:54, while the slowest was the twenty-fifth, when the watches showed 9:46. This included the time occupied at the pit in taking on supplies. The Lozier was not pushed during the latter portion of the race and Mulford played safe. He had a lap and a half at the finish over the National, the Illinois trophy winner.

Besides the four cars that finished, there started in the big race at 10 o'clock this morning a Black Crow, driven by Stinson; a Marmon, with Harroun at the wheel; an Alco, driven by Grant; a Simplex, with Saynor up; a Kissel-kar, with Harry Endicott in the seat; the Dawson-Marmon; the Matheson, handled by Basle; the Knox, with Oldfield driving, and Schiefler's Jackson—surely a most brilliant field. Undoubtedly had it not been for accidents early in the race the contest would have resulted in the greatest road battle ever fought on American highways. The Alco's career was brought to an end by a twisted clutch which put it out of the race at a time when its chances looked bright.

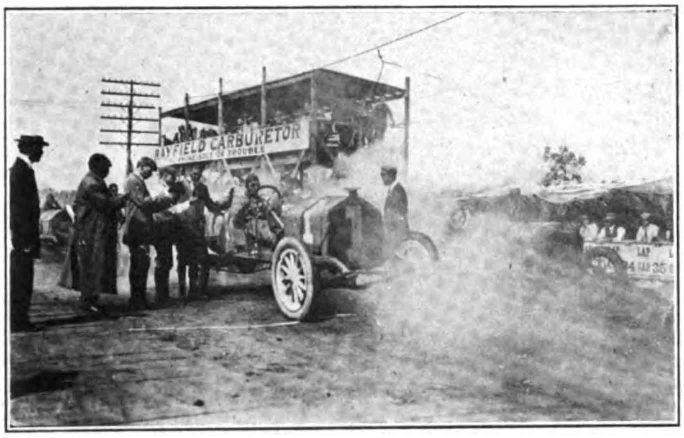
Marmon No. 4 was also put out on the same round by a frozen piston that eliminated the yellow car. Then Simplex No. 5 began to have tire trouble, which eventually put it out of the running—it stuck to the finish, however. With its most dreaded rivals eliminated, the Lozier settled down to a steady grind that landed the cup without much trouble.



Lozier winning the Elgin trophy



Falcar lined up at the tape



National, a great performer and winner, at the tape

National No. 1 Wins the Illinois Trophy

No. 1 National, a demonstrating car entered by the Chicago agents and converted into a racer by stripping it of the body, yesterday won the Illinois trophy for cars of from 301-450 cubic inches piston displacement and removed all doubts as to the speed of the Elgin course. The winner averaged 60.6 miles per hour for 203 miles and went the entire distance without a single stop, its large fuel capacity enabling it to hold out to the end, while its tires went through without a mishap. From the outset the National never left the result in doubt, leading from start to finish and at times showing some remarkable bursts of speed. Second to the National was No. 2 Falcar, which averaged 57.2 for the distance, while third was No. 6 Marmon, which made 56.9 miles per hour. There were just 4 seconds difference between third and fourth, the Midland having the advantage over No. 7

Alco, No. 6, in foreground; No. 8 Simplex behind

National, the former car averaging 54.7 and the latter 54.6. The race attracted a field of eight starters, of which five finished, while two of the others were running when the flags dropped for the final time. Only one car was put out of commission, that being the KisselKar, which went out after the tenth round because of radiator trouble. Besides the cars mentioned the other starters were No. 4 Falcar and No. 8 Lexington.

From the outset the two Nationals started to make a runaway of it, and for a time it looked as if they would accomplish their purpose. No. 7, being the first away, started to beat it from the beginning, and while No. 1 kept as close as possible it never was really dangerous after No. 7 had put in its four remarkably fast laps in the second, third, fourth and fifth rounds, in which it was clocked in 7:52, 7:54, 7:55 and 7:57.

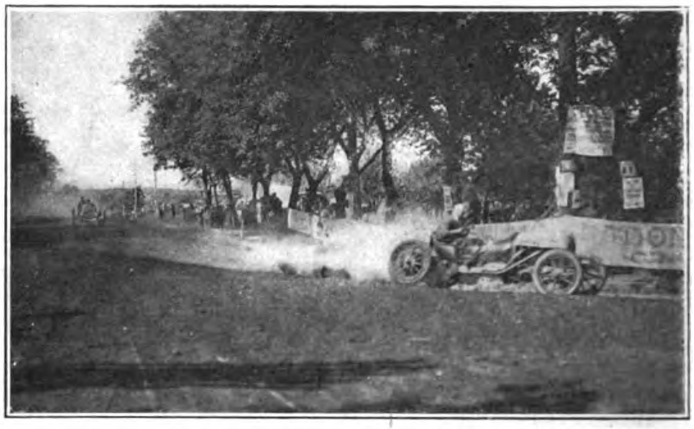
Cole, performing like a veteran, cutting in ahead



Staver-Chicago doing a turn like a whirlwind

Comparing the times of National No. 7 in the Illinois and the Lozier in the Elgin National, the tables show that the former went faster for twelve laps on Friday than did the latter in the big race to-day. There wasn't much difference, however, the National figures being 96:34, as against 97:10 for the Lozier. At the end of the fifteenth round the National still had the advantage by 52 seconds, but from this point on the Lozier had the advantage. A comparison of times of the two races for twenty-four laps, the distance of the Illinois cup event, shows that the National did 201:08.53 for his twenty-four laps, while the Lozier did 193:13.

Kane County Trophy Goes to the Marmon

Marmon No. 26 after a heart-breaking 169-mile race yesterday won the Kane County trophy event, in which seven cars of the 231-300 class competed. The Marmon's performance was a most noteworthy one, its average for the distance being 55.1 miles per hour. It won by a margin of 3 minutes 7 seconds over the Marion. The other Marmon, No. 23, was placed third and an Overland got fourth. The Marion averaged 54.2 miles per hour, Marmon No. 23 51.9 and the Overland 46.2.

The three cars that failed to go the distance were the Corbin, the KisselKar and the Cino, which met with mishaps before half the race had been run. The Corbin went nine laps before a broken frame caused its retirement; the KisselKar went eight and then pulled out because of a broken piston rod punching a hole in the crankcase, while on his second time around the Cino hit a telegraph pole at McQueen and was down and out.

The Cino accident was the first of the race. It had made a good getaway and at the end of the first lap was third to Corbin's first and the Marion's second. At the McQueen turn the Cino was running with two other cars, one of which was the Overland. These three were bunched approaching the turn and driver Fritzsch claimed he got the sign from the Overland mechanic to come ahead. But the Overland did not swing over, he asserts, and this left the Cino pilot the choice of going into the ditch or hitting the Overland. He chose the former, and hit a telegraph pole, bouncing from that into a barbed-wire fence. The Cino was so damaged in the mix-up that the radiator was put out of commission and it was declared out. The driver and his mechanic also were cut up some by the barbed wire, but neither was seriously injured.

The Kane County trophy race was the most interesting of the day from one viewpoint, that being the uncertainty that attended the running of the contest. It was no walkaway for any of them, five of the seven cars holding the lead at one time or other.

Fox River Trophy Goes to the Benz

With but one chance out of 34, Europe made good yesterday when a 30-horsepower Benz, a car of German manufacture, won the Fox River trophy which was offered in the small car race at 135 miles in which the eligibility line ranged from 161 to 230 cubic inches piston displacement. The Benz was the one foreign car entered in any one of the four events, and from the start it divided favoritism with the Cole. But the final results showed that for once the public had not sized up the situation properly for the Benz never left the result in doubt, leading from start to finish and beating the second car, a Warren-Detroit, by nearly 26 minutes. Of the six that started in the event only three finished, the Staver No. 36 sliding into third place. The Benz averaged 54.1 miles per hour for the distance, the Warren-Detroit did 46.1 and the Staver showed 44.9.

Originally there were eight cars entered in the event, but the weighing in yesterday afternoon resulted in the technical committee refusing to pass the two Fords, which had been entered by the Ford Motor Company. This decision was caused by the failure of the two cars to come up to the minimum weight of 1,400 pounds, which had been set for the 161-230 class. There was no question as to their eligibility as a stock car proposition, but No. 38 Ford hit the beam at 1,075 pounds, while the other Ford was even lighter, 950 pounds. Henry Ford positively refused to permit of bringing either one of his cars up to weight by the fitting of extra heavy seats, which might have enabled them to reach the coveted mark. Mr. Ford declaring that the Fords he had offered were stock cars and that it would be going directly against his principles of light-weight construction if he added extra weight in this manner. The decision of the technical committee was appealed by Thomas J. Hay, manager of the Chicago Ford branch, but the referee refused to reverse the technical committee's finding which ended the Ford incident.

The Chicago Motor Club brought about an innovation in the starting of three races which were to be run simultaneously. Instead of starting the Fox River first, and then following with the other two, as if all three were in one field, the 301-450 class was sent away at 30-second intervals followed immediately after by the Kane County cars. Then there was an intermission of 20 minutes before No. 32 Staver in the Fox River got away. The idea in this was to have as many cars running at the finish as possible and thus add to the interest. The scheme worked out well and all three of these races came to an end at almost the same time.

The following table shows the fastest laps made in the various events:

Car	Driver	Time	H. P.	Race	Lap No.
National No. 7	Livingstone	7:52	64.5	Illinois	2
National No. 7	Livingstone	7:54	64.3	Illinois	3

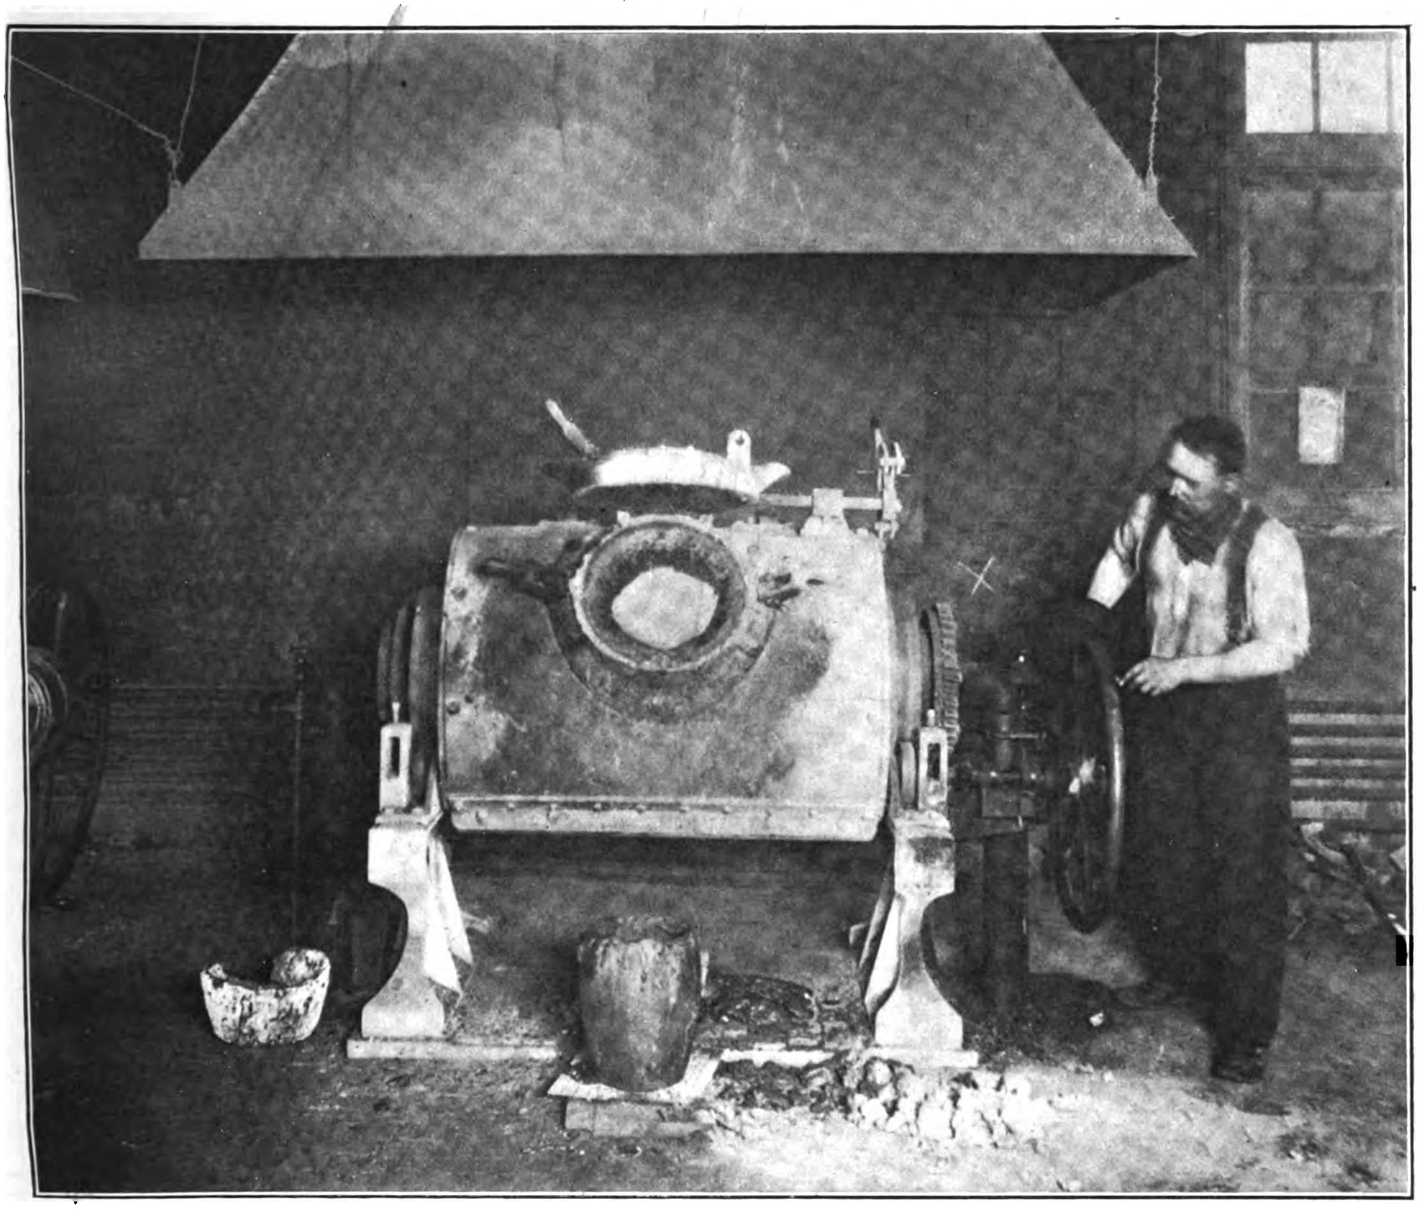
DEVOTED TO THE DISCUSSION OF ENGINEERING PHASES OF AUTOMOBILING, INCLUDING DESIGNING AND CONSTRUCTION FEATURES OF PRODUCTS, AND INFORMATION TO AUTOISTS



EXAMPLE OF ADVANCED FOUNDRY PRACTICE IN AUTOMOBILE PLANTS—TAKEN FROM THE MAXWELL

SIMPLICITY is worth more than every other feature combined, not only in an automobile, but in every other character of machine that has to be run by man. Confining this question to automobiles, there is more to be said for simplicity than there is when the same term is applied to a locomotive or a ship. The automobile is operated, for the most part, by men who know almost nothing about mechanical contrivances, nor is it possible for most of them to grasp the principles involved except in a vague sort of a way.

On account of the difficulty involved in getting the owners of automobiles to appreciate the things that they ought to know something about, and to eliminate the situations that can be of no great value, it is quite easy to foist upon the industry a considerable number of things that no longer adhere to the older arts. It is possible for men who know very little themselves to invent complication and find a ready market for it. But is it easy for the men who invent simplicity to make a living in this field? Supposing a man were to propose to show how it would be feasible to do without 1,000 of the 9,000 kinds of parts that are used in the average automobile, how much would he be able to sell the plan for? Nothing. Let some other man design a complication and offer it for sale; how many autoists are there who would refrain from trying it out? Very few.

In defining simplicity as it refers to automobile work, let us not be deceived; leaving off half of the essentials will scarcely serve for the purpose; making a carbureter do half of the work that a carbureter is supposed to do is not the proper course; a carbureter, for illustration, is better able to do this work than a cylinder of a motor. In a word, confine the carbureter to its proper function; keep the cylinders doing their share, make the magneto do ignition work only. Be sure that the spark plugs are capable of holding up their end. Such is simplicity in automobile work.

Likewise, throughout an automobile, if the units and the components thereof are so designed that they will do the work for which they are intended, the chance of failure at any point will be much reduced. But if the magneto, for illustration, is defeated by spark plugs that are incapable of standing the wave of electromotive force that the magneto is capable of impressing the result is complication.

As an indication of the ills that follow complication of this sort, it is only necessary to point out that the motor will perform badly, if at all; the carbureter will apparently function badly, and the autoist, no matter how much experience he may have, will be much puzzled.

In trying to get out of trouble in the face of this complication, the autoist will soon have the car in a state of bad repair; the carbureter will be out of adjustment; the magneto will be out of time, and the whole situation will be in just the state that a doctor finds a man when he is troubled with several disorders, no one of which will respond to treatment—impoverished blood is the real disorder.

As another instance of the definition of simplicity, some designers prefer to make one bolt do two things; other designers use a bolt for one purpose only. Which is the nearer to right from the point of view of simplicity? Certainly one bolt doing two jobs disposes of a part. On the other hand, is it in the interest of simplicity? When an owner of a car finds that repairing is necessary, is he so likely to understand a complicated situation, and is it not true that the mechanism is complicated when one bolt is used to hold two parts in place? Does it not assume the proportions of a mechanical puzzle? The repairman receives a certain amount of money per hour for his time. Is he likely to take more time solving a mechanical puzzle than he will occupy if he merely removes two bolts instead of one? When one bolt is placed to do two kinds of work it is possible that it may be subjected to two kinds of stresses, and the strength of the bolt may not be equal to the occasion. At all events, when this question of simplicity is solved, it will take into account all of these matters, and it is quite possible that the end will be different from that which the average man pictures in his mind.

Safe Handling of Gasoline

TELLING OF THE DANGERS, AND ILLUSTRATING SOME OF THE METHODS THAT ARE EMPLOYED AS SANCTIONED BY LIBERAL EXPERIENCE.

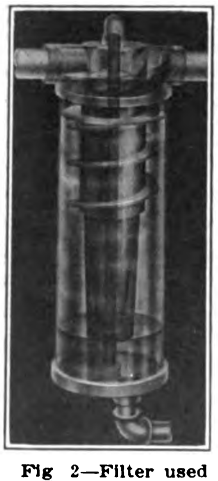


Fig 2—Filter used on Bowser gasoline storage tanks

UTILITY, as it resides in the automobile as a mode of transportation, depends quite as much upon the fuel available as it does upon the excellence of the mechanism. If, then, the fuel must be taken advantage of, certainly it must be stored in sufficient quantity to enable one to draw upon the supply as the occasion requires, without at the same time feeling that it is a source of too great responsibility to have it in hand in quantity sufficient to represent a fire hazard. It may not be generally appreciated, but even coal, when it is stored, must be carefully provided for to keep it from becoming ignited; spontaneous combustion is likely to set in unless it is properly ventilated.

The list of fuels available in the world include coal, wood, peat, hydrocarbons (in liquid form), alcohol, composite mixtures (made up of hydrocarbons, alcohol, nitrate of ammonia, picric acid, acetone, benzol, etc.), and if the matter is carried to its final conclusion, nitro-glycerine, gun-cotton, gunpowder and other explosives may be placed in the category of fuel.

Glancing at the fuel situation with a view to a further and more intimate acquaintance with it leads up to the question of the real dangers involved in the manipulation of the various grades and generic types of the same. Energy, of which there is a fixed amount in the universe according to the present belief, may be classified, referring to its various places of abode, as follows:

(a) Energy of position, that is to say, the energy that is stored in a mass, as a brick in an elevated position on the wall of a building, or a rocking boulder in the highest peak of a far-off mountain.
(b) Muscular energy of animals.
(c) Energy of the wind.
(d) Energy of vegetation.
(e) Energy of water.
(f) Energy of coal.
(g) Energy of liquid fuel.
(h) Energy of fuel in gas form.
(i) Energy of explosives.
(j) Chemical energy.
(k) Electrical energy.
(l) Energy of the sun's rays.
(m) Energy of impact.
(n) Energy of recoil.

What is energy? Briefly, it is a capacity for doing work.

What is work? It is the overcoming of resistance through distance. Another way to define work is to say, it is the product of moving force into distance.

When energy is expended work must be done; time is taken to do the work. The difference between energy and work, then, is the difference between the capacity for doing work and the doing of it. All energy that is not active resides in static form, as energy of position; that is to say, the energy is potential, ready to be freed, when, in time, it will perform work.

The energy as it resides in the various classes of fuel is measured in heat units and it has a mechanical equivalent.

Remembering that the measure of energy called the heat unit is the amount of heat that will raise the temperature of one pound of water one degree Fahrenheit (taking pure water at the point of its maximum density), it is a further step in the right direction to also remember that Joule's equivalent, the mechanical

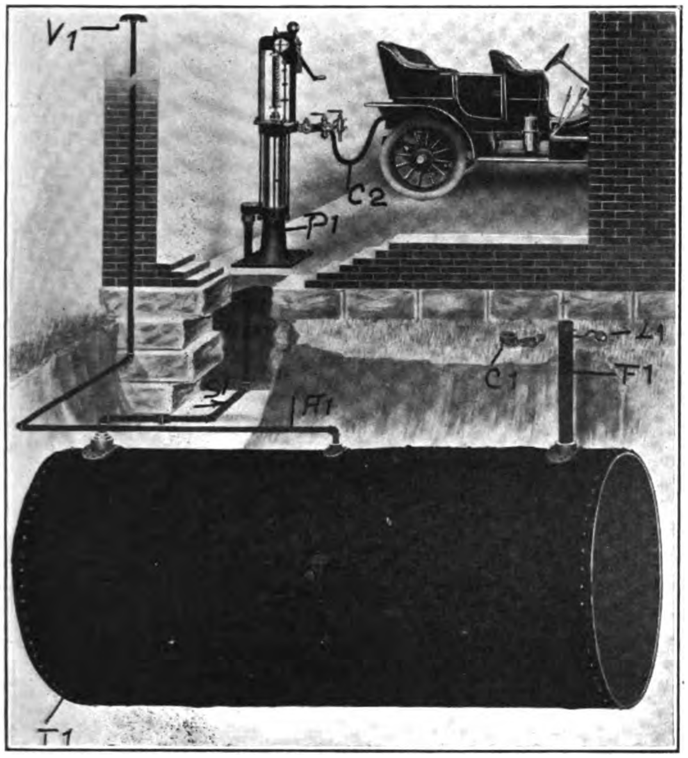

Fig. 1—Illustrating the most approved method of placing a storage tank of steel under ground near a garage

equivalent of heat. is equal to 142.4 foot-pounds. From this point on it is easy to frame a measure for power, as horsepower, so called, since it is stated that 33,000 foot-pounds equal one horsepower.

The Great Point of Difference to Remember

In the further discussion of the fuel problem, if it is the aim to properly differentiate, account must be taken of the time required to convert the energy that resides in the several generic types of fuel into useful work. The difference between the use of nitro-glycerine and coal, as a fuel, is largely in the difference in time required to abstract the energy from the respective forms. It takes quite a little time to abstract energy from coal; it requires but an instant to wring the energy out of nitro-glycerine.

Let us look into one other phase of this problem before striking the main road of the discussion. The most commercial way to abstract energy from coal is to burn it. The best way to burn coal is to set it on fire in the presence of enough oxygen to form carbonic acid and water. There are substantially 14,000 heat units in a pound of good coal; the energy may be abstracted from the same if the coal is completely burned in the presence of enough atmospheric air to supply the requisite amount of oxygen. The reason why the energy cannot be abstracted from coal as quickly as it can be from nitro-glycerine is because the oxygen of the air cannot be quickly combined with the carbon and hydrogen in the coal. The reason why nitro-glycerine gives up its energy so quickly is because the oxygen is combined in the mixture in more acceptable form, or the ingredients for freeing oxygen in the process of burning are in a better position than when atmospheric air is relied upon as the storehouse of the necessary oxygen.

As an illustration of what happens when explosives are not properly contrived, it is only necessary to remember that ordinary black powder, as used in blasting, etc., is far from smokeless; the smoke is due to incomplete combustion, the amount of oxygen present in acceptable form being less than that which would be required for complete combustion.

To sum up, remembering that time is an important factor when energy is displayed in the process of doing work, coal is better for fuel under a steam boiler than nitro-glycerine, because it burns fast enough to accomplish the commercial purpose of its being, whereas nitro-glycerine would introduce a monstrous hazard, and eliminate the germ of commercialism—disaster would be the normal expectation instead. When it is desired to destroy, as in war, nitro-glycerine and other explosives are preferred, the reasons being sufficiently clear to render further elucidation futile.

But if coal is too slow-burning to serve for purposes of war, and explosives are too vigorous to work advantageously under a steam boiler, it follows that in other walks, as when internal-combustion motors are to be used to furnish the power for automobiles, some other form of matter holding energy may be a better selection.

The internal-combustion motor has no need for a boiler because the fuel is burned directly in the presence of the mechanism that translates the energy. Any residuum, as ash, would clog up the machinery, and coal would deliver an abundance of ash. Liquid fuel, while it is composed of over 83 per cent. carbon (a form of coal), seems to be suitable for the purpose for two reasons, *i.e.* (a) the residuum, as ash, is relatively a mere trace, and (b) the fuel is more acceptable from the point of view of the combining of the requisite amount of oxygen to burn the fuel to complete combustion.

It is in the hydrocarbon series of fuels that reliance is placed, for the present, as fuel for automobile motors, referring to just the hydrocarbon compounds that are normal as liquid, but of which it may be said, the volatility is relatively high. Some hydrocarbons are normal in gas form, others may be found in solid form. Let it be understood right here, that all the hydrocarbons, before they will suitably mingle with oxygen of the air, must be vaporized; that is to say, they must be changed in their state of aggregation from solid and liquid forms to the gas form; even in the gas form, before they will burn, they must be combined with oxygen.

These hydrocarbons differ from all forms of explosives to the extent that they do not hold in their make-up the quantity of oxygen necessary to support combustion; indeed, there is very little oxygen in the hydrocarbons that survive in liquid form.

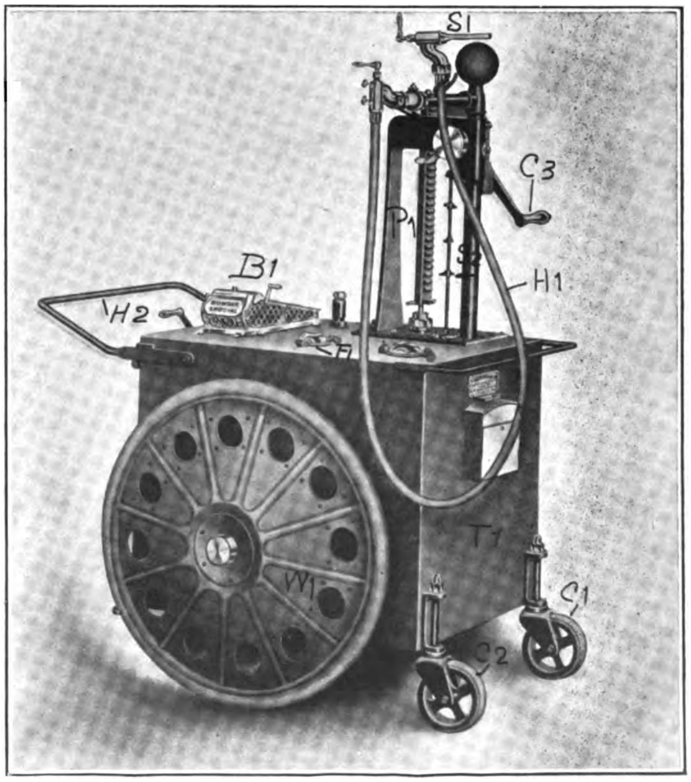

Fig. 3—Garage portable tank and pump, with facilities for noting and keeping track of the gasoline taken out of the tank

The most acceptable form of liquid fuel, then, may be regarded as holding qualities as follows:

(A) It should hold the maximum possible amount of energy in it per pound.

(B) The specific gravity of the fuel should be as high as possible in order that the amount of room that will be taken by it per thousand heat units will be low.

(C) It should be so volatile that it will vaporize within the available time.

(D) The boiling point (temperature of ebullition) should be as near the temperature of the surrounding atmosphere as possible.

(E) It should be capable of abstracting its oxygen from the air, nor should the compression or temperature have to be beyond that which is readily procured by simple mechanisms.

(F) It should deliver up its energy so readily that it will make for efficiency under normal working conditions.

(G) It should not, under any circumstances, deliver up its energy faster than the same can be disposed of safely.

Automobile gasoline answers to this description to a marked degree.

The Problem of Proper Storage Remains

Knowing all the requirements of the fuel and having one that responds to the needs, all that remains is to learn how to store and keep the same. Perishable substances, as eggs, beef and gun-cotton, must be stored in such a way as to preserve them. The fact that eatables will spoil if they are not properly kept is well appreciated; it is worth noting that gun-cotton will also spoil if it is not properly stored; but when it does spoil, unlike beef, it explodes.

Unless automobile gasoline is properly stored, it, too, will spoil, but, unlike gun-cotton, it will not explode. Instead of becoming more explosive as the result of spoiling in storage, automobile gasoline becomes less so, and in one sense this is a fortunate circumstance.

The only thing that can happen to automobile gasoline if it is not properly stored is that it will fail to serve for its purpose.

Of course, if automobile gasoline is allowed to leak out of storage and mingle in the atmosphere in the right proportion, it will, in the presence of a flame, burn. The force of this quick release of so much energy is enough to set fire to the surroundings and do quite a little damage of one sort or another.

Being sufficiently volatile for the purpose for which it is stored and ultimately used, it must be locked up much more securely than water for illustration. Extremely volatile hydrocarbons will penetrate the pores of a glass bottle; automobile gasoline holds in its make-up very little of the extremely volatile constitutent; but it is composed of a series of distillates, some of which are sufficiently volatile to penetrate the walls of a poor storage tank. To keep the gasoline intact it is necessary to provide a tank the walls of which are so dense that the more volatile portion of the fuel will remain, and in this way the autoist is assured of the fact that the fuel will not deteriorate while on storage, and he will also abort the chance of a fire.

How This Process Is Worked Out in Practice

If an autoist wants to run his car with the greatest measure of economy, the first thing to consider is the purchase of the fuel in packages large enough to afford to him the lowest price that can be negotiated.

Letters

ANSWERS TO INQUIRIES WHICH WILL THROW SOME LIGHT ON THE METHOD OF DETERMINING THE SPECIFIC GRAVITY OF GASOLINE; REMAGNETIZING PERMANENT MAGNETS; THE REFRIGERATING EFFECT OF GASOLINE; THE USE OF MANOGRAPH CARDS, ETC.

Might as Well Determine S. G. of Peaches and Pears

Editor THE AUTOMOBILE:

[2,347]—I have been told that the specific gravity method of determining the quality of gasoline is not now used; please tell me why. I am sure that there are others who would like to know more about this matter. Permit me to say that I have learned a great deal about the fuel problem in THE AUTOMOBILE. It is to be hoped that you will continue the effort that you are making.

Grand Rapids, Mich. P. E. F.
